JOURNAL OF PHOTOGRAPHY.

No. 3218. Vol. LXIX. FRIDAY, JANUARY 6, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. J. Malton Murray sends us an account of one of the leading portrait establishments in New Zealand, namely, the Bartlett studio at Wellington. (P. 3.)

In a leading article we lay emphasis upon some of the items requiring special care in the use of large-aperture lenses. Neglect of such considerations is frequently the cause of a lens being blamed for defects which it does not possess. (P. 2.)

Full working details for the Carbro process were recently given by Mr. A. C. Braham in the course of a demonstration of this method of making carbon prints at the Royal Photographic Society. (P. 4.)

In a recent paper in the "Physical Review," Mr Charles B Hodgman has given formulæ for a large number of light-filters, together with indications of their spectral properties. (P. 6.)

The Royal Photographic Society has already announced the date for the forthcoming autumn exhibition, namely September 18 to October 28. (P. 1.)

Official notice has been published of the registration as a company limited by guarantee of the Professional Photographers' Association of Great Britain and Ireland. (P. 10.)

Objection to an autumn P.P.A. Congress and recommendation of petrol vapour incandescent lamps for portraiture are the subject of letters from correspondents. (P. 11.)

A fitment for holding framed pictures conveniently for copying, and also for allowing a suitable adjustment of the artificial lights, is described by a contributor to "Assistants' Notes." (P. 7.)

A new type of non-slip printing frame and a machine for glazing are described in recent patent specifications. (P. 8.)

A process has been devised for the regeneration of hypo from fixing baths simultaneously with the deposit of the silver contained in the solution. (P. 2.)

Ownership of copyright in photographs made independently by an employee may at times be highly obscure in the absence of clear business arrangements. (P. 1.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article, Mr. H. J. Campbell is at pains to show the facility and quickness of making three-colour paper prints by the Raydex process. He describes his own manipulation in detail. (P. 1.)

Particulars of a modified two-colour process, patented by J. F. Shepherd and Colour Photography, Ltd., in which a yellow image is added to a combination of blue, green and pink, are given on page 3.

The Goraky process of colour cinematography has been supplemented by a new optical device for the simultaneous taking of the three colour-sensation negatives. (P. 4.)

Further details of the automatic three-colour camera of A. Ronald Trist will be found on page 3.

EX CATHEDRA.

The R.P.S. Exhibition. In the current issue of its Journal the Royal Photographic Society makes early announcement of the time which has been fixed for the next annual exhibition, namely, from September 18 to October 28, 1922. This will be the sixty-seventh of the exhibitions which have been held without interruption and, as in the case of others during recent years, will comprise not only pictorial photography but colour transparencies and colour prints and scientific and technical exhibits relating to photography. We are very glad that this early announcement has been made, and we take this first opportunity of drawing the attention of technical and scientific workers throughout the world to the service which they can render photography and the Society by contributing to this section of the exhibition. We are sure we can say, on behalf of the Society, that it will welcome exhibits illustrating the applications of photography in manufacture, research and nature study, and also work by photo-micrographic and X-ray methods in the same fields. Anyone having employed photography in these ways is asked to place himself or herself in communication with the Society for the purpose of making the forthcoming scientific and technical section fully representative of what is being done in the various countries of the world. Full particulars of the exhibition are obtainable on application to the Secretary, 35, Russell Square, London, W.C.1. The latest day for the receipt of entries is August 25.

* * *

Copyright in Semi-Free-Lance Photographs. A question which not infrequently arises as to the ownership of copyright is concerned with the taking of photographs, say for newspaper illustration, by a photographer who is employed to make them for a firm or individual, and at the same time has the opportunity of taking subjects "on his own." It is hardly necessary to explain that the copyright in photographs taken by such a photographer in the course of his ordinary employment are the property of his employers; and in the absence of evidence to the contrary it is a natural assumption that all photographs made by him become the property of the person or persons regularly employing him. Disputes in these circumstances arise from the absence of definite evidence that such and such exposures were made for the employers and such and such others by the photographer for himself, presumably at his own expense in materials and out-of-pocket charges. It would seem that even when there is a definite general agreement that a photographer shall take subjects for himself in the intervals of work for his employers, there can be no certainty as to the ownership of the copyright in a given subject except by a written document formally earmarking such and such subjects as having been made by the employee on his own initiative and at his own cost.

Unquestionably the disputes which arise in circumstances such as these would be avoided by a straightforward business system which would distinguish in writing between one section and the other of the photographer's work.

* * *

Hypo Recovery. A method of throwing down the silver contained in used hypo baths and at the same time of regenerating the hyposulphite for the fixation of further negatives or prints has recently been patented in Germany by A. Steigmann. According to the "Kolloid Zeitschrift" the process consists in adding to the exhausted fixing bath, which preferably should be heated to a temperature of 120 to 140 degs. F., a small proportion of sodium hydrosulphite, commonly called "hyposulphite" by chemists, together with an equal weight of soda carbonate. The result of this addition is to throw down the silver as a granular deposit of the metal. It is stated that after filtering off the silver mud the bath is ready for further use. Apparently, the action of the hydrosulphite takes place only in an alkaline solution, and therefore is not applicable in the seemingly simple form described above to acid fixing baths, which would require considerable addition of carbonate of soda for the neutralisation of the acid or acid salts in them. In any case, we should not regard the process as of value, except in treating large quantities of bath, such as those used in the fixing of cinematograph films. Even at the present price of hypo, recovery of this latter for use again is a proposition of extremely doubtful economy; and if the sole object of treating exhausted baths is the recovery of the silver contained in them, it is unlikely that a more satisfactory process can be found than the one commonly in use of adding a sufficiency of liver of sulphur.

BLAMING THE LENS.

The growing use of large-aperture lenses calls for much more skill and care in their working than most workers realise, as conditions under which an instrument with an initial aperture of *f*/8 will work quite satisfactorily are not at all ideal when the aperture is increased to *f*/3 or even *f*/4.5. We have recently had complaints as to the performance of lenses of high reputation, the charges being that they were deficient in covering power and that they had even less depth of definition than could have been reasonably expected.

Before condemning a lens, it should be ascertained beyond all doubt that the fault is not in the camera. The present tendency is to build cameras with the idea of portability rather than rigidity, and it is probable that this is to blame for many defects for which the lens is blamed. The majority of very rapid lenses are fitted to light hand-cameras, and these are more easily put out of truth than most people are aware. Cameras in which the front is supported by metal uprights call for very careful usage, as they are easily strained to an extent that will vitiate the performance of the most perfect lens. It is difficult to detect this by any ordinary method of inspection or measurement, especially when the front is much smaller than the plate, so that recourse must be made to some such device as that, which we believe was first suggested by Messrs. Taylor, Taylor and Hobson. It is the use of a small but delicate spirit level. Assuming that the ground glass is parallel with the back frame of the camera, the latter is stood upon a carefully-levelled surface, and the level placed upon the front cell of the lens. If the bubble is stationary while the level is turned round it may be assumed that the necessary degree of parallelism exists. Greater accuracy may be attained by levelling a glass plate upon three screws, and after removing the plate, standing the focussing screen directly upon the screw points or heads, as the case may be. This eliminates any error which might occur from unevenness in the back frame due to inequality in leather covering or the slight projection of fittings. This test will not, of course, indicate whether the error, if any, is due to the front or back of the camera being out of truth; it may be that in some cases the central position of the swingback has been incorrectly marked or that its fittings have been strained.

Next in importance to parallelism of front and back comes the register of the slides with the focussing-screen or the scale of distances. This, when working with large apertures, must be extremely accurate, for although it may not be so wrong as to give the impression of general unsharpness, it may so far disturb the relative positions of the pointer or screen as to give the effect that the lens is lacking in depth, the fact being that all the available depth is in front or behind the point upon which the lens was supposed to be focussed. Slides and screens of the ordinary type are easily tested by means of a simple depth gauge consisting of a stout strip of wood through which a screw passes. The strip is placed across the frame of the slide or screen and the screw turned until it just touches the surface of the ground glass or plate. We have found it a good plan to place a cigarette paper between the screw point and the glass and to bring the screw down till it only just allows the paper to be withdrawn. This is more certain than trusting to inspection of the contact, for if the spring behind the plate is weak the screw may press it down, and in such a case there would be enough pressure to hold the paper. It is desirable to test various parts of the surface, as it is possible that one end of the plate may be farther from the lens than another. As an illustration of the necessity for accuracy in register, it may be mentioned that a well-known optician uses for testing a dark slide of which the frame is made of stout brass, the focussing being effected upon a ground glass plate, which is replaced by the sensitive plate for exposure.

The scale-focussing arrangement often leaves much to be desired, even assuming that the distances are accurately marked. The principal fault is too great a distance between the pointer and the engraved surface. In such a case it is difficult to set the scale twice to exactly the same point. Bending or twisting of the pointer increases the risk of error.

A supposed lack of covering power is sometimes caused by constructional defects in the camera or exposing shutter. An inner frame may actually obstruct the field of the lens; or a before or behind lens shutter, by reason of too small an opening, may do the same thing. If this be suspected the lens should be fitted upon a camera of sufficiently large size to allow of the whole circle of illumination being received upon the ground glass.

Unsatisfactory definition of the image as a whole may be, but seldom is, due to faulty construction of the lens, but is more often caused by some injury which has disturbed the adjustments. A common cause is careless fitting to a between-lens shutter. If the lens has been fitted by the maker there is little likelihood of this, but if a camera maker has done the work it is possible that he may have gone wrong in several ways. The faces of the mount may not be parallel, the front and back tubes may not be concentric, or, a most important point, the separation between the components may be altered. It has occurred that when the length of the lens tube has prevented a camera from closing, the workman has calmly turned down the tube until it is short enough. When

such fitting has taken place it is a necessary precaution to compare the work of the lens in the shutter with that which has been done with it in the original tube.

Good lenses should be disturbed as little as possible. Constant unscrewing of the cells for cleaning is apt to wear the threads and destroy the centering, and on no account should the glasses be removed from their cells, the turning of a lens of a few degrees having sometimes a distinctly prejudicial effect upon its performance.

If a lens does not come up to the purchaser's expectations, the safe and proper course is to send it direct to the makers for inspection and report. It is as detrimental to the maker as to the user for a faulty instrument to be in circulation, and if the lens be actually faulty it will probably be put right without charge, even if the fault be not acknowledged. We recently handled a lens by a good maker, which was obviously defective, and on returning it were informed that one of the combinations belonged to another series. It was immediately put right free of all cost, with thanks for submitting it.

PROFESSIONAL WORK IN NEW ZEALAND.

In New Zealand a photographic studio which employs two or more persons, including the proprietor if he works in it, is a factory within the meaning of the Factories Act. This is no degradation to the profession, although it has had curious results. For instance, during the war, when parents and relatives were clamouring for photographs of the boys going to the Front, the Bartlett Studio was prohibited from working all the overtime it would have worked, because the Department of Labour had to see to the due enforcement of the law. Consequently, many relatives were kept waiting longer than they would have been if things had been otherwise.

I have been told that the best work—at any rate, the most expensive work—is turned out in Christchurch. I had a couple of busy days in Christchurch a little while ago, but had no opportunity to interview photographers there. Perhaps some day in the future I may have that pleasure, as it is almost certain I shall visit Christchurch more than once again.

In the meantime, however, I have had the pleasure of a chat with Mr. Andrews, who controls the Wellington Branch of the Bartlett Studio, the other being in charge of Mr. Bartlett at Auckland. This studio may fairly be considered as one of the best in New Zealand. I am not in a position to pass judgment on the professionals here as a body. But I am quite sure that anything that equals or excels the work turned out by the Bartlett Studio must be something very good indeed. This being a democratic country, there is, speaking broadly, no graduation between the studios doing first-class work and those which one might, without offensive intention, describe as just ordinary. There are, I understand, good workers here and there in some of the larger provincial towns, but it is in Wellington, Christchurch, Auckland and Dunedin that one finds the best workers. The other towns have not a population able to support the man who does high-priced work.

The work of the Bartlett Studio is of a very high order, and equals, I think, that of the best work at home—always bearing in mind that the run of customers able to appreciate really artistic work is limited. In the reception room at Wellington one may see some really choice examples. The room is, by the way, a very tastefully arranged one, calculated to make a favourable impression. Mr. Andrews is a young man of energetic temperament and decisive personality, who thoroughly understands his work. His taste may be gauged from the circumstance that he is an admirer of the work of Bertram Park and Pirie Macdonald. Also he likes to make soft-focus portraits, although he has to subordinate his love for this class of work to meet the wishes of many of his sitters. He had experience at home, and while there considered that Walter Barnett ranked amongst the soundest and best of workers.

Mr. Andrews has very definite ideas on treatment. He never photographs a man against a light background. He used in my case a dark green background and a blue side screen. He does not consider a light background suitable for masculine portraits. Neither will he put men into ovals and circles. The strong rectangular is, in his view, the correct form for virile male portraits—and he certainly succeeds in producing portraits distinguished by life and character.

There is furniture in the studio, but Mr. Andrews photographs people, not furniture. He mentioned in chat having removed a high-backed elaborate chair—suitable for a bishop—because so many people wanted to be taken seated in that chair, which was quite unsuitable in most cases. What furniture there is, is good.

Daylight is used for most exposures, but there is a small battery of half-watt lamps for night work or use blended with daylight. To the sitter's left there are three 3,000-c.p. lamps hung high behind a diffuser, and one 2,000-c.p. to the front and right of the sitter. Mr. Andrews does all his own operating, and is a deft hand in the studio. It is big enough to accommodate a group of 60.

Before the war platinotype was the principal process. Now the work is almost exclusively development paper, toned. Folio mounts are invariably used, with the print usually mounted with a margin of harmonious tint superimposed upon soft-toned brown mounts. At one time India proofs were a feature; the sketch portrait fashion had a certain vogue, but the studio sticks to sound, entirely good work that one can bear to live with day by day. There is no straining after freak effects; everything is artistically sound, and yet there is variety in treatment and individuality about each portrait.

The studio sticks to studio work. Outdoor and home photography are not sought after, and no attempt is made to cater for amateurs in the developing and printing line. Outdoor work here is not easy. In Wellington particularly a still day is rare—generally there is a breeze, and often half a gale of wind. One gets used to that, and goes sniffing for a breeze if a quiet day happens along. But as a photographic proposition, garden parties and the like are not attractive, and the results little likely to enhance the photographer's reputation. The fact that Mr. Andrews has had no slack time for ten years would seem to show that the policy followed is correct.

The prices obtained may be estimated from the following:—

	£	s.	d.	
Whole plate in folio mounts ...	5	5	0	per doz.
Cabinets in folio mounts ...	3	10	0	,,
Cabinets similar in style, smaller	2	10	0	,,
C.D.V. or thereabouts ...	1	10	0	,,

Enlargements range according to size and finish all the way from one guinea to ten guineas, framed complete.

Most of the business is done on a credit basis. The cash business is small, and bad debts practically negligible. The studio is run on business lines, with card files and files of proofs enabling back items to be turned up rapidly when reprint orders are received. The workrooms are well laid out and efficiently conducted. Mr. Andrews has an eye for talent, and he pays a salary of £550 per annum to a man who began some years ago in the studio on quite humble work. But he developed, introduced a feature that made a substantial

saving in the workrooms, and now does work that two men previously did.

There is no apprenticeship system. Juniors are started, and if they prove capable they get plenty of opportunity to progress. It is worth noting that Mr. Bartlett had a valuable ally for some years in a man who came out from home. Contrary to our Canadian friends, the New Zealand photographer seems to have been fortunate in the quality of assistant who has come from the Old Country to these shores.

The studio favours British goods, although its experience in recent years has not provided encouragement. At present the conditions do not, in Mr. Andrews' view, tend to the development of consumption of British material. It takes a long time to get material from home, and if any of it should chance to be faulty the waste of time, correspondence, and inconvenience are heavy adverse factors.

The Bartlett Studio photographs all the celebrities as well as the humbler elements of social life here. The folk up country come to Wellington for a holiday and to have their photographs taken. Many of the studio's customers are families, and one or another is always coming along. As a matter of fact, I believe if the studio were removed from its present central position in Wellington to some private and out of the way domicile, the clients would follow. There is, of course, only a limited opening for professionals doing the quality of work turned out by the Bartlett Studio. And although I don't suppose Messrs. Andrews and Bartlett would mind in the least, I do not advise any professional at home who is on a good wicket to set sail at once for "Noo Zee." We are doing our little best to keep smiling under the thumps of a pounding slump, and it's likely that the wealthy sheep-farmers who are now selling (at 9s. per dozen) sheep, complete with fleeces—that cost them 33s. each—will not be spending lavishly on photography for a while. That Mr. Andrews is as busy as ever during such a slump will, I think, be admitted as evidence that I have not exaggerated his ability as a business man and an artist.

J. Malton Murray.

THE CARBRO PROCESS.

[The following full report of the demonstration of the Carbro process, given by Mr. A. C. Braham before the Royal Photographic Society, is published in the current issue of the Society's "Journal," and is of particular value on account of its clear instructions in the making of Carbro prints by so practised a worker in the carbon process as Mr. Braham. The many examples of the process shown on the occasion of the demonstration amply illustrated the ability of the Carbro process to give the full gradation of the negative through the medium of a bromide print. Mr. Braham, whose opinion merits every respect, specifically declared that an expert carbon printer could make as good a carbon print by this process as the best he could make in the ordinary way by printing on carbon tissue, with the single qualification that there would be a difference if the negative was one containing critically sharp detail which it was required to reproduce.]

Mr. Braham reminded his audience that the process was founded upon Ozotype. The final picture was a carbon print made from a bromide print. The first chief requirement in Carbro printing was plenty of water and its free use. The worker must remember that he was dealing with a bromide print, and there was a danger that bleaching might not be regular, consequently the risk of getting patches unless the wetting was complete; also the tissue after it had been in the bath was thoroughly expanded, and if a piece of transfer paper which had only been perfunctorily soaked were taken and the two papers brought together, one of them having been thoroughly expanded and the other not, there was a stress and pull upon them, and complete contact would not be obtained.

The working baths consisted of the following formulæ:—

Stock Solution No. 1.

Potass. bichromate	1 oz.
Potass. ferricyanide	1 oz.
Potass. bromide	1 oz.
Water	20 ozs.

Stock Solution No. 2.

Glacial acetic acid	1 oz.
Hydrochloric acid (pure)	1 oz.
Formaldehyde 40 per cent.	22 ozs.

For Use—First Bath.

No. 1 stock solution	6 ozs.
Water	18 ozs.

For Use—Second Bath.

No. 2 stock solution	1 oz.
Water	32 ozs.

The second or acid bath should be made fresh each time of use; the other might be used for a considerable time. The temperature of the baths was important, and it was as well to work at a temperature which was constant.

Mr. Braham then recapitulated the various stages. In the first place the worker provided himself with a good bromide print. That bromide print was soaked in water, so that it thorough wetting being that in that case the absorption between the bromide print and the tissue which had been in the bath of potassium bichromate and ferricyanide would be equal. The tissue was immersed in the first (the potassium bichromate and ferricyanide) bath for three minutes. Then came the critical point when the user of the process must decide on the nature of the transcript of the bromide that he wanted. This governed the time in the second (the acid) bath. If it was desired that the Carbro print should be like the bromide, 20 seconds would be about the time; if greater contrast was desired, a shorter time would be given, and if a flatter result, a longer time. But the number of seconds was always conditioned by the particular bromide paper which was being used, although the rule held constant for all bromides; the more time the softer the result, the less time the harder the result.

Having put the tissue into the second bath for the required time, it was taken out and brought into contact with the bromide print, squeegeed, and allowed to remain in contact for a quarter of an hour, which was usually sufficient, although if a decidedly darker print was wanted, it might be left for 20 minutes or even more. The tissue and print should be put between grease-proof paper, because the use of bibulous paper resulted in the abstraction of some of the solution from the tissue, with the result that there might be patches. The tissue having remained in contact for a quarter of an hour or the stipulated time, it was stripped away from the bromide print, the bromide print was put into the dish to wash, and the tissue was brought into contact with a piece of transfer paper which had previously been soaked for a good time in cold water.

The print then remained in contact for, say, half an hour, and development took place as in the case of a carbon print, though it had to be borne in mind that the solubility was greater, and that a lower temperature should be used for the Carbro print than would be used for making the carbon. When the development was more or less complete, hotter water could be used, if desired, just as in ordinary carbon printing, but the start should always be made slowly.

Mr. Braham carried through the various manipulations, and mentioned other points as he went along. It was always desirable to have a white margin on the bromide as a safe edge. Sufficient depth of solution in the bath was desirable so as to avoid airbells, for a good depth enabled one to slide a piece of tissue under the surface. During the immersion of the tissue in the first bath he rocked the dish gently so as to break any airbells which might be present. At the end of three minutes he removed the tissue and allowed it to drain for 15 seconds, then dropping it into the acid bath and again rocking the dish. At the end of 20 seconds he took it out again and laid it squarely on the print. A palette knife was extremely convenient for lifting after squeegeeing papers on to one another or on to a glass support, and that was one of the necessary tools in this process. The tissue having been squeegeed on to the bromide print, was kept in contact for a quarter of an hour in order that the bleaching action might be complete.

It would be asked what sort of bromide was best for using with Carbro? Any type of bromide could be worked, although gaslight prints were not so satisfactory as the normal bromide. He had used various makes of paper; all of them worked, but a difference would be found in the time which various papers required in respect to the acid bath. That was a matter which each worker must determine for himself by experience. With regard to the number of Carbro prints which could be made from one bromide, he had been accustomed to say that the limit was ten, but he had had to revise his estimate. He passed round a bromide print from which fifteen Carbro prints had been taken, and it was still, apparently, as good as ever. That print had been fifteen times soaked, and fifteen times brought into contact with the tissue, and fifteen times stripped and washed, developed, and washed again. But there was not even a trace of blistering, although usually, when a bromide print was used time after time, if the paper did not disintegrate, the gelatine blistered.

A print of a kind could be made without the interposition of the acid bath at all, and he showed an example or two, but such a print was almost invariably clogged up in the shadows and had the high lights washed out. With regard to the times in the different baths, the time in the acid bath was governed by the worker's own fancy for a particular result, but the time in the case of the first bath was fixed at three minutes, with the one exception of the case of red chalk, where a modification had to be made. Evidently the pigment employed had some effect on the gelatine.

After the tissue and the bromide had been in contact for the required time the tissue was stripped away and brought in contact with the soaked transfer paper and squeegeed. He did not use any pressure to prevent curling, as with proper squeegeeing this was unnecessary. The washing of the bleached prints should be thorough, and they could be redeveloped with ordinary developer.

As the effective part in a bromide print was reduced silver, it had occurred to him that it might be possible to make some paint of the nature of water colour which should contain silver so as to serve in working up a bromide print which could then be reproduced a dozen times in as many Carbros. He showed a bromide which was worked up in this manner, with a water-colour containing Indian ink. Just a few touches of the brush charged with the pigment were given, and all those touches were reproduced in the Carbro as part of the Carbro image, with as complete a transference, thanks to the reduced silver in the pigment, as any other part of the bromide.

In reply to questions, he said that if olive brown or sepia were used, the time of immersion in the acid bath must be varied. With the normal time, olive brown gave a flat, and sepia a harsh, result.

Asked whether the combined bath had been given up, and what were the outstanding differences between that and the original Ozobrome bath, he said that the question of the original Ozobrome bath was one that he could hardly answer. It was a patented process, and the baths were sold as proprietary solutions. In the single bath method there was not the means of control by varying the time. The differences in result he had been able to secure through the modifications which were made possible by the two baths would be sufficiently evident from his demonstration. This, he thought, was a considerable advantage, even if it was the only advantage to be gained from the new method. He did not want to discuss the old method, but rather to emphasise the possibilities of the new.

Asked whether he used ordinary unsensitised carbon tissue, he said that this was necessarily so. Any of the ordinary tissues were available. As to a matt or glossy surface, he preferred a matt surface, which was easier in manipulation. In the Carbro prints the detail was rather on the soft side, but the carbon process itself did render such knife-edge sharpness wherever needed, that he wondered whether a glossy surface would render that detail on the final print.

On the question of matt or glossy surfaces in general, he preferred a matt effect, but there was no reason why a glossy paper should not be used. With regard to detail, if it were a case of the reproduction of a mechanical drawing, he did not think that sharpness in the same sense as lens-sharpness would be so well forthcoming in the Carbro as in the carbon print, but in pictorial subjects this did not signify. Here what was involved was a diffusion process, and the action in Carbro was lateral as well as downward, so that, speaking in absolute terms, there would be a loss of sharpness.

In reply to other questions, he said that he did not fix the prints in hypo after redevelopment, but used them as they were. If a bromide intensified by re-development, he thought that it was a case of slovenly work, the print not having been properly washed. As for the necessity for immediate redevelopment, he had believed that this necessity held good, until, working at an exhibition when he had no chance to redevelop immediately, he found that on redeveloping after two days there was no difference. In a case in which there were stains on the bromide of which the worker had been unable to get rid, he would be inclined to ask what was the matter with the original bromide print? Asked whether the development of the bromide print to begin with had any marked bearing on the result, he said that he thought it had: if development had not been full, there was not that reduction of silver which was required, and also the silver was not in the condition in which it gave the best results. The development of a Carbro print, he said, in reply to another question, might be done at a decidedly lower temperature than a carbon. If a print was too dark notwithstanding the warmth of the water, ammonia could be put in the developing water, but he did not like this procedure. Asked whether he had ever experimented by making Carbros from bromide prints, which had been treated with an intensifier or a reducer, he said that he did not see any reason why a bromide print should not be used, a part of which had been removed with ferricyanide.

A Prosperous Film Company.—Declaring a dividend of 15 per cent. on the ordinary shares at the annual meeting of the Stoll Film Co., Ltd., Kingsway, Sir Oswald Stoll said that very few companies in the industry had done so well. "The film industry in general," added Sir Oswald, "is one which, when it casts its swaddling clothes and acquires strength in limbs, brains in its head, and more character in its composition, is going to astonish mankind with its general usefulness."

The Soho Reflex. We have always had the highest opinion of the Soho reflex camera, which embodies within itself practically every feature which the ideal reflex should have, and, moreover, is of light and most workmanlike construction. An illustrated booklet of the various models has just been issued by Messrs. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W. It contains a full list of the reduced prices for these cameras which have come into force at the beginning of the present month. Photographers will congratulate Messrs. A.P.M., Ltd., on the reputation for excellence of design and workmanship which this camera of all-British origin and manufacture has obtained throughout the world.

LIGHT-FILTER FORMULÆ.

THE following short paper from the "Physical Review" collects the results of a large number of experiments made by Mr. Charles D. Hodgman, of the Case School of Applied Science, primarily for the production of light-filters for three-colour photography. As will be seen, however, the series include many filters applicable in photography of coloured objects on orthochromatic and panchromatic plates.

In the course of a somewhat extended study of the processes of three-colour photography a considerable number of filters of various types have been worked out. They include a series of three-colour filters of varied extent and abruptness of absorption, various yellow or orange contrast or compensation filters, and others for various special uses, such as photo micrography and contrast control in the photography of coloured objects.

The filters constructed were of the ordinary type, each consisting of two glass plates flowed with coloured gelatine, and, when dry, cemented together with balsam. The factors determining the selective absorption are the strength and dye content of the gelatine solution and the volume flowed per unit area. The flowing solution consisted in each case of 6 per cent. by weight of clarified gelatine, a definite quantity of one or more aqueous dye solutions, and distilled water to make the whole up to 100 per cent. Any filter is thus fully determined by giving for each of its two components (1) the dye used and the strength of aqueous stock solution, (2) the quantity of this dye solution used in 100 parts of the final mixture, and (3) the quantity flowed on unit area. The gelatine solution is filtered and poured while still warm on the previously cleaned and levelled glass plates.

The action of the filters is shown by photographs of their absorption spectra. It is possible, however, to indicate the characteristics

Filter.	Formula. Dye Solution.	Quan'ty.	Coating.	Plate.	Limits of Action. Microns.

* Orange G and fluoresceine will not dissolve in water in the proportion stated. Ammonium hydroxide is added drop by drop until solution occurs.

approximately by giving the limits of action in the spectrum. Such an attempt is made in the accompanying table in connection with sufficient data for exact reproduction.

In choosing filters for any specific purpose, it should be noted that the action obtained is limited by the sensitiveness of the photographic plate used and the character of the light-source. Due allowance must be made for these factors. The following data refers to absorption spectra for which the light-source was an incandescent tungsten filament in a gas-filled bulb of light blue colour. This lamp is supposed to produce an approximation to daylight, and is commercially known as "Mazda C 2." The spectrum of this source on the brand of panchromatic plate used is continuous from about 0.35 μ to 0.72 μ. A region of less action exists at about 0.52 μ. The ordinary plates, not colour sensitised, showed action without filter from 0.35 μ to 0.55 μ. In the case of the orthochromatic plates the action was extended to about 0.63 μ.

The first group listed is a series of red filters differing principally in the position of the limit of absorption toward the blue. While origionally intended for three-colour work there are many other uses for which such filters are suitable.

The next two groups comprise green and blue three-colour filters of various characteristics. Among these are certain yellow and negative green filters giving with ordinary or orthochromatic plates a range of action desirable in the blue and green sensation negatives in three-colour work.

The series of orange and yellow contrast filters is in effect a continuation of the red series, absorbing decreasing amounts of the blue and violet. Two, Nos. 16 and 18, show an approach to the distribution of visual intensity.

The fifth group comprise filters which of themselves, or when combined with the limited sensitiveness of ordinary or orthochromatic plates restrict the action to relatively narrow limits.

The last five filters, previously listed for use with ordinary or orthochromatic plates, are here used as negative green filters with panchromatic plates.

For each component part of each filter, indicated as "*a*" and "*b*," there are given (1) the name of the dye used and the concentration of the aqueous stock solution, (2) the quantity of stock dye solution used for each 100 c.c. of the final mixture, and (3) the volume of coating solution for each sq. cm. area. In addition to the dye solutions, each coating mixture contains 6 per cent. by weight of gelatine and distilled water to make 100 per cent.

CHARLES D. HODGMAN

FORTHCOMING EXHIBITIONS.

1922.

January 11 to 27.—Camera Portraits, entitled "Men of Mark," by Walter Stoneman, at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1.

January 21 to February 4.—Partick Camera Club. Particulars from the Hon. Secretary, James Whyte, 51a, Peel Street, Partick, Glasgow.

February 7 to 11.—Sheffield Photographic Society. Latest date for entries, January 21. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield

February 11 to 25.—Scottish Photographic Salon. Latest dates, entry forms, January 23; exhibits, January 31. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Latest date for entries, January 30. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Latest dates, entry forms, February 4; exhibits, February 9. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

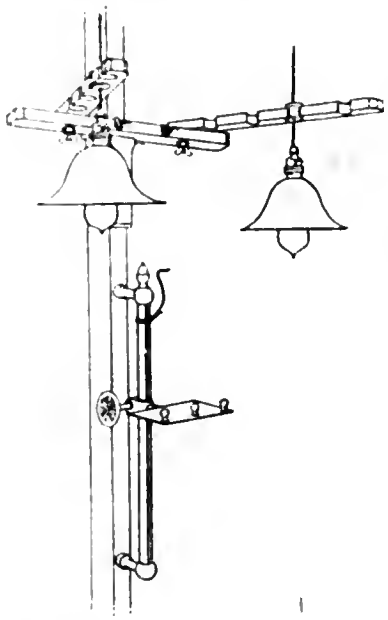
September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Mechanical Device for Use in Copying Framed Subjects.

THE copying of photographs and various subjects, requiring to be reproduced in the studio, is frequently done through the glass of a frame; most work being in a better condition for copying, under pressure behind the glass. Such subjects thus need more room for adjustment to the lens than is generally afforded by the ordinary copying easel, so that it becomes necessary to fix them up before the camera in some other way. I have found the method shown in the drawing to answer the purpose well. The means of artificial lighting when required will perhaps easily be seen. I have utilised a post for support which occupies a convenient position for day lighting, and the two wooden movable arms work on a piece which is clamped to the post, and can be raised or lowered; the lamps have also weighted suspenders, and work up and down, the lights,



of course, being shaded from the lens. But the most novel feature of the method is the mechanical device used for supporting the framed pictures, etc., for copying, and this, though a rather elaborate bit of machinery, worked out by a handyman with engineering experience, proves itself worthy of its "post." It is bolted to the same upright post, the platform upon which the picture stands being connected with a clamping collar, and made to work smoothly up and down the upright iron bar, and clamped by a screw at the back, to the required elevation, by a turn of the wheel. It is easy to adjust, and the strength of grip makes a safe support for a fairly heavy weight. A wire twist working up and down the upright bar serves to steady, or sometimes to hook, the frame in an upright position. The groove seen in front of the upright bar engages with a ridge inside the collar, and retains the platform in a frontal position. The camera is fixed to a table which runs to and fro on castors.—M. B.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 19 to 24 :—

TRIPODS.—No. 34,541. Tripod stands for photographic, etc., apparatus W. M. Gillard.

APPARATUS.—No 34,272. Apparatus for treatment of strips of photographic film. F. J. M. Hansen.

PROJECTION APPARATUS.—No 34,364. Apparatus for photographic lantern-slide projection. A. N. Wight.

CINEMATOGRAPHY.—No. 34,520 Method of treating cinematograph films to eliminate scratches, etc. A. F. M. Ott.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

THREE-COLOUR CAMERAS.—No. 164,476 (March 6, 1920). The invention consists of a camera in which three plates are successively exposed through filters connected in turn with the optical system so as to vary the effective aperture of the filters relative to one another for maintaining a constant time of exposure through each filter.—Arthur Renald Twist, Coronation House, 4, Lloyds Avenue, London. [Further particulars of the invention are given on another page in the "Colour Photography" Supplement.]

TWO-COLOUR PHOTOGRAPHY.—No. 169,533 (June 30, 1920). The main claim is for a process of colour photography which consists in preparing two negative-records, one of which is a record mainly of the green constituents of the object, and the other is a record mainly of the red constituents, preparing positives therefrom and colouring the image of the positive of the green record negative magenta or minus green and the image of the positive of the red record negative blue-green or minus red, preparing a third positive by printing from the two negative-records combined and superimposed in register, colouring the image of the third positive yellow, and combining the three-colour positives in register.—John Frederick Shepherd, 10, Derwentwater Road, Acton, London, W.3, and Colour Photography, Ltd., 3, St. James's Street, London, S.W.1. (Particulars of the process are given on another page in the "Colour Photography" Supplement.)

PRINTING FRAMES.—No. 168,728 (July 2, 1920). The invention refers to photographic printing frames of the type having the back made in two parts each provided with the separate spring clamping device and one of which parts is intended to be unclamped and raised for viewing the print during the progress of the printing operation while the other part remains clamped in position. In such printing frames it has been proposed in Patent Specification No. 3,648 of 1904 to provide means in conjunction with the last-named part of the back to lock or anchor the part against the adjoining end rail of the printing frame by means of a hook pivoted either on the surface of the back or on the adjoining end rail of the frame to engage with a stud fixed either on the back or fixed on adjoining end rail, the hook to be so formed that its curved portion is eccentric with its working centre so that it clamps the part of the back against the adjoining end rail.

The invention consists in forming a hook or slotted member integral with or fixedly attached to the spring clamping device and at or about right angles thereto, the hook being adapted to engage with a pin or stud mounted on the adjoining end rail of the printing frame, and providing a cam or eccentric surface on either (*a*) the operative edge of the hook or (*b*) on the pin, in which latter event means are provided on the pin to impart a partial rotation to the latter after the hook has been forced into engagement with the pin; and thus locking or anchoring means are so combined with the clamping device and the parts so constructed and arranged to act that when the clamping device on the last-named part of the back is operated the anchoring or locking means are simultaneously brought into engagement and either (*a*) automatically locked or (*b*) locked by turning the pin whereby the part of the back is simultaneously (1) clamped against the print, etc., in the frame and (2) anchored or locked fixedly against end rail of the frame.

In the drawings, the detachable back of the photographic printing frame 2 is formed in two parts 1 and 1^a hinged together and is shown provided with the well-known centrally pivoted clamping springs 3, 4. In order to prevent the clamped portion 1 of the hinged back from slipping, while the portion 1^a, after being unclamped is raised for inspecting the print, means are provided

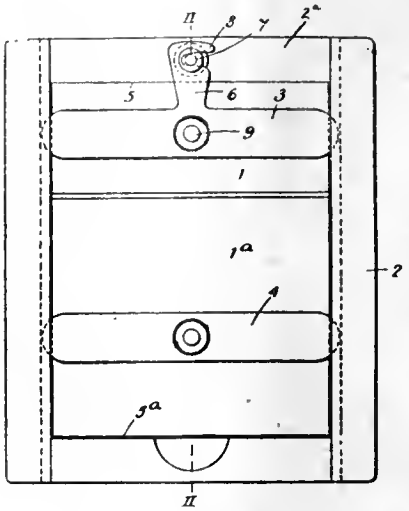


Fig. 1.

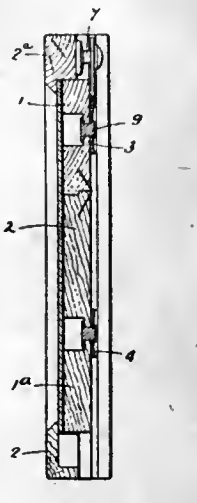

Fig. 2.

for holding the transverse edge 5 of the clamped portion 1 of the hinged back tightly and securely clamped to the adjacent corresponding edge of the end rail 2^a of the frame 2. Such a clamping movement may, as shown in figs. 1 and 2, be attained by a single cam device centrally located with respect to the width of the frame.

The cam device illustrated comprises a pivoted hook member 6 engaging with a fixed abutment or pin 7, *i.e.*, fixed on the rail of the frame; and the drawing, wedging or clamping movement is effected by providing the hook 6 with a cam drawing edge 8 for engagement with the pin 7. In operation, the number of movements of the hand is reduced by reason of the hook 6 being integral with the clamping spring 3, the hook and spring being conveniently stamped in one piece, so that both revolve about the same pivot 9. With this construction the transverse edge 5 of the portion 1 of the detachable back will be automatically drawn into close contact with the corresponding edge of the end rail 2^a of the frame 2, and securely retained in that position in conjunction with the frictional resistance or pressure set up by the clamping spring 3, by the usual movement of the clamping spring 3 when closing the frame 2.

As shown in figs. 3 and 4, the wedging or cam surface instead of being provided on the hook or slotted member is formed on the abutment. The hook 6^a is provided with an edge 8^a adapted to engage with a cam surface 10 on a bolt or pin 11 which latter is

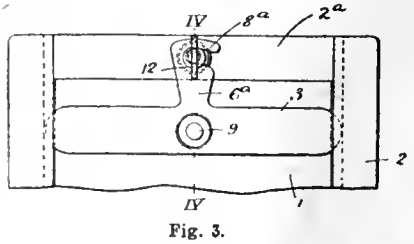

Fig. 3.

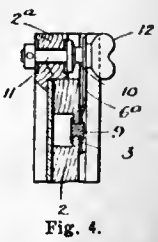

Fig. 4.

suitably mounted in the end rail 2^a of the frame 2 so as to be capable of rotation by means, for instance, of a cross-head 12.

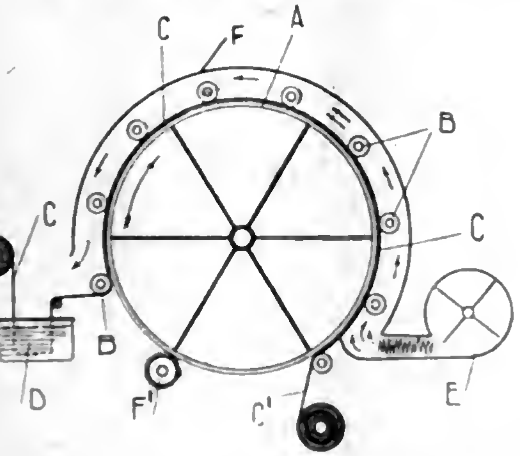
In operation the spring clamp 3 and hook 6^a would be first moved into the position shown, and the pin 11 is then partially rotated so as to cause the cam surface 10 to draw the hook 6^a and thereby the back portion 1.—Houghton-Butcher Manufacturing Co., Ltd., Clifford Road, Walthamstow, London, E.17, and Alfred Joseph Dennis, The Langdales, Connaught Avenue, Chingford, Essex.

Print-Glazing Machines.—No. 165,158 (March 16, 1920). The apparatus comprises a polished rotary drum, preferably of steel, over which the paper to be treated is fed, preferably from a continuous coil, the paper being previously moistened. The paper is pressed into contact with the surface of the drum by means of pressure rollers and a heating arrangement is provided which transmits heat over the external surface of the paper on the drum.

The heat is preferably greatest at or about the point where the paper leaves the drum, the heat being regulated to prevent injury to the gelatine surface of the paper.

A suitably driven rotary brush may be provided in contact with a free portion of the surface of the drum to keep the drum surface constantly polished.

In the drawing, A is a polished steel drum of a breadth slightly wider than the paper to be treated, the drum being



mounted upon its horizontal axis. A series of rubber pressure rollers B are arranged in contact with the outer surface of the drum so that they are rotated about their horizontal axes by the drum.

The paper to be polished is arranged in a coil C, passing through a water trough D guided by suitable rollers, and thence under the rollers B, being led off the drum and coiled up again at C^1. A casing F is arranged around the portion of the drum over which the paper passes and a heating arrangement and a fan blower E are arranged in the casing at the point where the paper leaves the drum. A high speed rotating brush F^1 is arranged in contact with the under side of the drum to keep the surface continually polished.

In operating, the drum is slowly rotated in a clockwise direction and the fan E and heater are operated to drive a strongly heated current of air through the casing.—Asmo Catini, 30, Via Roma, Turin.

The following complete specifications are open to public inspection before acceptance:—

Focussing-Devices.—No. 172,974. Focussing devices for photographic apparatus. J. Krone.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register.—

Iko.—No. 418,223. Photographic paper, photographic albums, and photographic mounts included in Class 39. Ilford, Ltd., Britannia Works, Roden Street, Ilford, Essex, manufacturers of photographic plates, paper and films.

A Lithographic Pioneer. The death has taken place in the Edinburgh district of Mr. Lachlan Sinclair, at the age of ninety-one. He was for sixty-eight years in the employ of Messrs. Nelson and Co.'s Publications, being one of the pioneers of the three-colour process.

New Books.

Converting a Business into a Private Company.—A handy little volume of this title has been written by Mr. Herbert W. Jordan, of the well-known firm of registration agents of Chancery Lane, London, W.C.2, price 1s. net. It tells in simple language the advantages which are obtainable from the conversion of a business into a private registered company, and explains the procedure and cost of carrying out the necessary conversion.

The Scientists' Reference Book and Diary.—This annual pocket reference volume published by Mesrs. James Woolley, Sons & Co., Ltd., Manchester, price 3s. 6d. net, appears for the year 1922 with its customary numerous pages of scientific facts of daily service to the chemist or physicist. It contains particulars of the Universities, learned societies, and other institutions, in addition to a diary for the year and postal and other general information.

Physics and Chemistry of Colloids.—The report of a general discussion held jointly by the Faraday Society and the Physical Society of London on the physics and chemistry of colloids in relation to various branches of manufacture has been published by H.M. Stationery Office for the Department of Scientific and Industrial Research, price 2s. 6d. net. The volume contains a large number of papers on the properties of colloid substances and processes. While the particular application of colloid chemistry to the making of photographic emulsions does not come within the scope of the discussions there is much in the papers on the properties of jellies and other colloid preparations which is of interest to experimenters in the processes of emulsion photography.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 3, the president, Dr. G. H. Rodman, in the chair.

Mr. W. F. A Ermen, M.A., read a paper "On the Conditions Affecting the Apparent Activity of some Organic Developers."

Mr. Ermen had begun a series of experiments with the object of finding some numerical measure of the "activity" of a developer, and of establishing some means of predicting the properties of a developer from the constitutional formula. An account of the many results obtained is not possible in the absence of the curves and tables embodying them, but it can be said that the bases of comparison were the maximum density produced in a given time of development, the depression in density due to bromide and the time of appearance of the image. From these results he was able to place developers approximately in an order of activity. He also described results of experiments on the effect of variation of soda carbonate on the activity of a developer, in the course of which a good many observations were made on the action of developers used without alkali. In conclusion he referred to the effect of desensitiser on the behaviour of developers.

A discussion followed, in which Messrs. R. E. Crowther, F. F. Renwick, G. E. Brown, C. M. Thomas, and E. W. Mellor took part, and on the proposition of the chairman a cordial vote of thanks was accorded to the lecturer.

Commercial & Legal Intelligence.

NEW COMPANIES.

AVERYS SERVICES, LTD.—This private company was registered on December 20 with a capital of £4,000 in £1 shares (1,000 preference and 3,000 ordinary). Objects: To adopt an agreement with A. A. W. Avery and to carry on the business of photo, colour, half-tone, and line process engravers, photo-etchers, artists, photo-printers, photographers, retouchers, photo-offset plate makers, and printers, etc. The subscribers (each with 100 preference shares) are:—F. Avery, 6, Bristol Road, Stratford, E.15, photographer; J. R. Avery, 6, Bristol Road, Stratford, E.15, draughtsman. The first directors are: A. A. W. Avery (permanent managing director), F. Avery, J. R. Avery, and Margaret E. M. Avery. Qualification, £100. Remuneration £50 each per annum.

UNDOCHROME, LTD.—This company was registered on December 15, with a capital of £5,000 in 4,750 10 per cent. preferred ordinary shares of £1 each and 5,000 deferred ordinary shares of 1s. each. Objects: To acquire and turn to account any inventions, patents and processes relating to photography or cinematography. The first directors are:—A. Martin, L15. Halton Mansions, N.1; G. G. Hacker, 9, The Parade, S.E.11; T. P. Middleton, Briarwood, Lower Bourne, Farnham (managing director). Minimum cash subscription, 100 shares. Qualification, 100 shares. Remuneration (except managing director), £100 each per annum (chairman £150). Registered office: 49, Devonshire Chambers, 146, Bishopsgate, E.C.

PRESLANDS, LTD.—This private company was registered on December 21, with a capital of £1,515 in 1,500 cumulative 7½ per cent. preference shares of £1 each and 300 ordinary shares of 1s. each. Objects: To carry on the business of printers, stationers, lithographers, typefounders, photographic printers and lithographers, artists, engravers, etc. The first directors are:—H. F. L. Williams (life director), 20, York Buildings, Adelphi; G. T. Thomas, 40, Leinster Gardens, Hyde Park; J. H. Skelton, Royal London House, Finsbury Square, E.C.2. Registered office: 7, Southampton Street Holborn, W.C.1.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION OF GREAT BRITAIN AND IRELAND, LTD.—This company was registered on December 19, as a company limited by guarantee. Objects: To promote the interests of members and associated members in their professional work; to watch parliamentary or public action affecting the interests of photographers; to deal with matters affecting professional custom and practice; to procure from insurance companies advantageous terms for members against business risks, etc. The management is vested in a council, the first members of which are:—H. G. Chase, 53, Widmore Road, Bromley Kent; C. F. Dickinson, 1, Myton Road, Dulwich, S.E.; A. Ellie, 2, Vinery Villas, Hanover Gate, N.W.; G. Hana, 22, Bedford Street, Strand, W.C.; A. Bennett, 56, Eagle Street, Southampton Row, W.C.; R. Haines, 4, Southampton Row, W.C.; F. Brown, The Limes, London Road, Leicester; T. Chidley, 14, Werburgh Street, Chester; W. Illingworth, 110, Abingdon Street, Northampton; F. Read, 97, Renshaw Street, Liverpool; H. C. Spink, 109, Western Road, Brighton; T. C. Turner, Regent House, Anlaby Road, Hull; A. S. Watson, View Park Studios, Bruntsfield Links, Edinburgh; H. Lambert, 32, Milson Street, Bath; A. Corbett, 48, Baker Street, W.; A. B. Brown, 100, Tottenham Court Road, W.; W. E. Gray, 92, Queen's Road, Bayswater, W.; R. N. Speaight, 157, New Bond Street, W.; F. Wakefield, 64, High Road, Chiswick; H. A. L. Chapman, 235, High Street, Swansea; W. H O. Wedlake, 358, Romford Road, Forest Gate; H. D. Wheeler, 9, Church Street, Folkestone; M. Adams, 43, Dover Street, W.; H. G. St. George, 112, Albany Street, W.; W. B. Chapman, 13, High Street, Windsor. Registered office: 9, Old Jewry Chambers, E.C.

News and Notes.

MESSRS. THOMAS ILLINGWORTH & Co. have issued an attractive calendar for 1922 embodying the firm's well-known horseshoe trade mark, and forming a striking piece of advertisement for Illingworth plates and papers.

R.P.S. FELLOWSHIP.—The following have been elected Fellows of the Royal Photographic Society:—Edgar R. Bull, Robert Chalmers, Francis Orville Libby, W. J. Smith, E. L. Turner, and Colin M. Williamson.

CARBRO DEMONSTRATIONS.—The Autotype Company have arranged to give a series of demonstrations of their Carbro process at their offices, 74, New Oxford Street, London, W.C.1, every Thursday afternoon during the present month between 3 and 5 o'clock. Any photographers will be welcome.

KODAK'S WINDOW-DRESSING PRIZE.—Over eleven hundred shops in London and the South of England entered the "Evening News" competition, in which cash prizes were given for windows typifying the Christmas spirit. A prize of £5 was won by the Oxford Street branch of Kodak, Ltd., whose photographic display secured 1,035 votes from the public.

SHEFFIELD PHOTOGRAPHIC EXHIBITION.—The exhibition arranged by the Sheffield Photographic Society will be held from February 7 to 11. There are two open classes, one for prints and colour transparencies, and the other for lantern slides. Mr. Bertram Cox will judge the entries, the last day for the receipt of which is January 21. Prospectus and entry form from Mr. J. R. Wigfull, 14, Parade Chambers, Sheffield.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The annual exhibition will be held at the South London Art Gallery from March 4 to March 25 Mr. Bertram Cox will be the judge in the three open

classes (pictorial photography, lantern slides, and technical and scientific photographs), and in the numerous members' classes. Particulars and prospectus are obtainable on application to Mr. Harry Abbott, 51, Beauval Road, East Dulwich, S.E.22.

THE CLUB PHOTOGRAPHER.—Contributions by members of the Birkenhead Photographic Association are made the feature of the January issue of the "Club Photographer." Among them is a variety of the Bromoil process, described by Mr. A. Shipley as "Oilograph," and specially suitable for transfer of the inked up impression. The "Club Photographer" is obtainable, 4½d., post free, from Messrs. Tutills, Ltd., 9, Swan Street, Manchester.

PHOTOGRAPHING STREETS FROM CAGES.—The large number of motor-car accidents in Paris (there were no fewer than 135 on a recent Sunday) have aroused the officials, and a few days ago the Paris police traffic squad were informed that for ten days a number of them would be installed in high-perched cages over leading thoroughfares. They will not only direct the traffic (said the official notice), but photograph motor-cars travelling to the danger of the public, thus securing unmistakable proof of the offenders' identity.

THE SERVICE COMPANY.—The directors report that the trading for the year ended September 30, 1921, has shown a net profit of £7,237 12s. 5d. Adding the balance brought forward from the previous year and deducting the interim dividend paid on the 6 per cent. cumulative preference and preferred ordinary shares, there is a balance of £7,792 13s. 7d. for disposal. After making full provision for bad debts, repairs and renewals, depreciation of premises, furniture, etc., and allotting £791 3s. 3d. to the employees' bonus fund, the directors recommend payment of (*a*) the full dividend on the 6 per cent. cumulative preference shares; (*b*) the maximum dividend of 10 per cent. on the preferred ordinary shares; (*c*) a dividend of 12 per cent. on the ordinary shares, placing £2,500 to reserve, thus increasing the reserve fund to £11,000. The balance of £3,359 2s. 8d. is carried forward to next year's accounts.

HOW A PHOTOGRAPHER BROUGHT BUSINESS.—A few days ago we heard of one method of advertising used by a photographer, which could be profitably used in your town, says an exchange. It is quite generally the custom, especially in high schools, for certain classes to make trips through different business houses and factories where the students can learn how business is carried on and how various things are manufactured. The photographer of whom we are speaking heard of this, and invited the principal of the local high school to bring classes through the studio to see how pictures are made. The school took advantage of his offer and the photographer explained everything. His apparatus could not fail to impress these coming citizens with the fact that photography was the business of skilled workmen, and that making pictures was far more than just pressing a bulb. The value of this demonstration, besides general advertising, was found in the fact that many of these students were interested enough in photography to come in later and have their pictures made.

Correspondence.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—In to-day's issue of your publication I note that in the report of the meeting of the Professional Photographers' Association held on December 9, Mr. Speaight states that it is gratifying to note that none of the resigning members found any fault with the Association.

May I say that I think this was a result of their restraint, and not because there were no faults to find. I have been a member for several years now, but living outside London I have had no benefit beyond the little "Circular" the Association used to publish and the privilege of attending the Congress (on payment of 10s. or so extra). Then recently the subscription was raised, but to balance this the little "Circular" has apparently been dropped, and a small page in a dealer's leaflet is all we get.

I wrote some time ago suggesting that the "Circular" should add to its previous information a review of all the new apparatus and gadgets that were put on the market, together with details of prices, etc., for the benefit of those members who did not live in London and could not spare time to run up to town often to keep *au fait* with the latest innovations. The secretary replied that he thought this a good idea and would bring it up at an early meeting. The result appears to have been the exact opposite. The firm which grants a page per month to the P.P.A. in their trade bulletin is, I grant, a very good firm, but we don't want our journal to be published by any firm interested in the trade. We want an unbiassed review of goods equal alike to all manufacturers.

And now to crown all the P.P.A. have decided to hold their Congress, the only remaining event now of any interest to provincial photographers, in September, and apart from the Photographic Fair.

Now do the Council realise that for a large number of their members September is out of the question as a month for them to leave their studios and go up to town for a week? All the seaside place at least are at the height of their best class season. April or May are slack months in most towns, and if Londoners object that it is *their* season, then let them remember that they live on the spot, and can slip out to the Congress for a few hours at a time or in the evening, but the provincial photographer cannot. He has to leave his business to the mercies of his staff for several days at least.

Can you wonder at the large number of resignations (134 according to the report) in face of these facts?

When the Association realises that the majority of its members are *outside* London, and tries to keep *their interest* sustained by a decent journal, a Congress in various towns besides London, and, if possible, by establishing district centres that could *do something*, then I can see their membership going up in leaps and bounds. At present they are simply committing suicide as an Association. I have written this not so much for the sake of grumbling as to try and rouse some life, if only by-an argument.—Yours truly,

H. L. KETTLE.

18, Ramshill Road, Scarborough,
December 23, 1921.

PETROL MANTLE LAMPS IN STUDIO PORTRAITURE.

To the Editors.

Gentlemen,—As I notice there are frequent inquiries in your columns respecting artificial illuminants for portraiture, I thought it may possibly be of interest to some of your readers, who, like myself, live in a place where no electric current is available, and who perhaps object to the great heat generated when using a number of burners for ordinary gas, to know that I have recently been experimenting with petrol lamps in this direction. There are doubtless many types of these lamps on the market, the particular ones I have tried are Zenda lamps, made by the Kitson-Empiro Lighting Co., of Stamford.

There are two lamps, carrying inverted mantles, and run from a cylinder of petrol placed on the floor, the lamps being connected with it by flexible copper tubing. In my own case I fitted reflectors, and hung the lamps on two iron rods attached to the ceiling in such a manner that they could slide along them, and also they were attached to a joint enabling them to be turned in different direction. It is of course necessary to light this type of lamp, by first igniting some methylated spirit, which has previously been poured into a trough provided in the lamp. After this has burned for a minute or so will have heated the burner sufficiently to allow the petrol to ignite the mantle when turned on from cylinder. The lamps are, I think, rated at approximately 800 c.p. each, and they give a light of beautiful soft quality. Using a lens of *f* 3, with 500 H. & D. plate I can obtain an exposure in one second, without the lamps being uncomfortably near the subject.

More lamps could, I understand, be run from the one cylinder if necessary.

I enclose a few proofs, from unretouched negatives, taken in the circumstances described.—Yours truly,

R. PERKINS.

Hill Road, Clevedon.
December 23, 1921.

[We are much obliged to our correspondent, whose prints show full exposure and remarkably good illumination in the shadows.—EDS., B.J.]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. H. H.—We believe all the three books you name are out of print, but they are by no means rare, and we have no doubt you could obtain second-hand copies from Messrs. W. and G. Foyle, Ltd., 121-123, Charing Cross Road, London, W.C.2.

C. H. TOMS.—Messrs. Houghtons, 88-89, High Holborn, London, W.C.1, are agents in this country for the "Photo-Miniature" series of monographs, the price of which is 1s. 8d. each post free. Issues which they may not be able to supply would perhaps be obtainable from the American publishers at 103, Park Avenue, New York.

J. H.—Two gas lights would be quite useless; at least a dozen are necessary if you want to give reasonably short exposures. It will therefore be better to rely entirely upon daylight. Have a dark blind over the lower part of the window up to 4½ ft. from the floor. Use a large white reflector on the shadow side, but do not place it too close to the sitter.

J. W.—(1) If of very pale colour a blue, green, or possibly a yellow glass might be used for modifying contrast, but for practical purposes the method is practically useless in comparison with the use of a suitable printing paper, or intensification or reduction of the negative. (2) A photograph obtained in the circumstances you mention is the copyright of the person who took it, and we know of no ground on which he could be restrained from making any commercial use of it.

A. B. C.—We are much obliged to you for your comments. Really there is no secret in making the index to the "B.J." except week-by-week supervision of its assemblage in slip form. The "copy" for the index is sent to the printers while two issues of the volume remain to be published; the entries relating to the subject-matter in these two issues are added to the proofs. A practical manual of the subject is "Indexing," published by Messrs. Grafton's, 7, Coptic Street, London, W.C., 7s. 6d. net.

CARDI.—For bromide printing, unless the negatives are of exceptional density, a 32 c.p. metal filament lamp is ample power. It should be fitted in the printing box so that the filaments run roughly parallel with the negative, that is to say the holder for the lamp should be fixed in the side of the box. For printing on gaslight papers, or for working from dense negatives, a very good lamp is a little 60 watt half-watt, giving a candle power of about 120. In this the filament is in the form of a ring, and the lamp holder should be on the floor of the printing box.

C. J.—So far as the photograph is concerned you are not running any risk in issuing the cards according to the customer's order. As regards the lines from a current Christmas card, these are probably the copyright of the Christmas card publisher, and the issue of them would be an infringement of that copyright, in respect of which both you and your customer would be equally liable. If, however, the quotation is from one of the poets copyright in whose works has expired (as is the case with most of the great poets) there is, of course, no infringement of copyright.

S. C.—Unless you are prepared to use plenty of light, and preferably electric metal-filament lamps, we certainly advise you to put on one side the idea of an enlarger without a condenser. If you are obliged to use gas, you had far better have a condenser enlarger, a very good model of which is the chain and sprocket of Butchers. The best gas burner we know for an enlarger is the "Howellite" sold by Griffins. There are no vertical enlargers on the market except the somewhat expensive ones sold for professional use.

COPYIST.—Probably the copyright has expired in the engravings and also in the original paintings from which they were made. If copyright in either form of the works is still in existence your reproductions would be an infringement. In order to satisfy yourself as to the existence of copyright it would be necessary to ascertain the dates on which the respective artists died. Even then it would be a rather complicated matter, since copyrights which were in existence at the time (June, 1912) at which the old Act was repealed, are prolonged by the present Act. We wish we could give you more definite information, but that is not possible from the brief particulars which you give.

W. A.—(1) A piece of dark red or green art serge, which you can obtain in 54-inch width, will make an excellent background. If you prefer you can use calico sheeting, distempered with black Kalko. You can get this in packets, price 1s. 6d., from the Vanguard Co., Maidenhead, or Messrs. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.2. (2) By rubbing gently on *very fine* glass paper. (3) Not as postcards, but as printed matter. The words "printed matter," and the address only may be written on the back. (4) We doubt if you will get any maker to supply odd sized mounts; buy the large sheets of card from a firm like Halsey and Davison, 14, Carlisle Street, London, W.1, and cut them up with a steel straight edge and sharp knife. If you dry-mount, the heavy-weight papers are quite stiff enough and easier to cut.

A. H.—(1) The only thing you can do is to stick up some kind of bust or other object, the image of which you can arrange and focus on the ground glass, afterwards yourself taking its place before the camera. We think if you arrange the head rest for the object when focussing, you will have no difficulty in putting yourself in the same position. (2) We do not think there is any mechanical shutter release, except, of course, the obvious one of a long length of rubber tube or metal cable release, which could readily be arranged so that it could be operated by the foot. Even the very simple device of a single flap raised by a thread and allowed to drop back after the exposure could be easily arranged by rigging up some kind of board, pressure on which with the foot would provide the requisite amount of pull on the thread. (3) There is no book on self-portraiture.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3219. Vol. LXIX. FRIDAY, JANUARY 13, 1922. Price Fourpence.

Contents.

SUMMARY.

In his "Paris Notes" M. L. P. Clerc mentions recent innovations in aerial photography, a new type of cinematograph projector, recent experience in Autochrome work, and the recent discovery of a pair of stereoscopic drawings made in the sixteenth century. (P. 15.)

In an address before the Annual Convention of the Photographers' Association of America, Mr. Pirie MacDonald discoursed freely of the principles which he had followed in his profession of photographer of men, and in particular on the course which he had found to be of advantage in establishing such relations of common interest between himself and his sitters as to lead to the making of a characteristic portrait. (P. 17.)

Opinions on the time fixed for the annual Congress of the Professional Photographers' Association are published from several correspondents. (P. 26.)

We point to eleven different forms of standing or overhead charge, a due proportion of each of which enters into the cost of every piece of work done in a photographic establishment (P. 13.)

The death is announced of Mr. David Bachrach, a pioneer of professional photography in America and an active experimenter in photographic processes. (P. 25.)

In a leading article we endeavour to show the value of observation in the carrying out of photographic processes. Every attempt to trace a defect back to its cause represents an addition of the most valuable kind of knowledge. (P. 14.)

At the Royal Photographic Society on Tuesday evening last the discussion on the desirability of manufacturers supplying figures indicating the contrast grading of development papers failed to elicit any considerable desire for such information on the part of users. Dr. Glover's paper, read in his absence through influenza, showed the practical difficulty of supplying really informative data. (P. 23.)

At the same meeting a most interesting demonstration was given of a new metal-filament projector lamp, suitable for enlarging and lantern work, which is just being introduced by the General Electric Company. (P. 23.)

In France the present year is being celebrated as that of the centenary of photography, the most recent inquiry having shown that the first permanent record by the agency of light was obtained by Niépce in 1822. (P. 13.)

According to a recent patent, self-toning emulsion is prepared with a compound of selenium or tellurium instead of gold. (P. 14.)

The leather or leather-cloth coverings on hand cameras, which have become shabby, may be renovated at little cost. (P. 14.)

The design of a direct-vision finder having special facilities in the use of a cinematograph camera is the subject of a recent patent specification. (P. 21.)

EX CATHEDRA.

Photography's Centenary. Our French friends, in the person of M. G. Potonniée, are just now taking an interest in determining, as accurately as may be done, the date which may be ascribed as that of the invention of photography. A paper by M. Potonniée in the Bulletin of the French Photographic Society, examines at length the stages in the early work of Nicéphore Niépce, who is rightly regarded as the first to produce a permanent record of objects by the agency of light. It appears from the early correspondence of Niépce which was published long after his death, and particularly in the now rare work by Fouque, "La Vérité sur l'invention de la Photographie," that in the year 1822 Niépce had succeeded in obtaining permanent copies by means of sensitive bitumen of Judea. As a result of his researches M. Potonniée rejects the earlier date of 1816, which apparently has been cited in reference to the earliest of Niépce's experiments with light-sensitive substances on paper. These, however, could not be rendered permanent. The year 1822 is confirmed by a number of Niépce letters of that date, and is in agreement with the tradition current in his family for a number of years after his death in 1831. Those who have visited the former Niépce's estate at Gras, near Chalon, will perhaps remember the monument standing near to the railway line, the inscription on which definitely names the year 1822 as that in which Niépce "invented photography."

* * *

Overhead. The eternal problem of how much to charge for photographic work which is different from the regular run of portrait offered by a studio is, perhaps, one which turns up more frequently than any other in questions which reach us on commercial topics. Putting aside considerations which are based on known competition which has to be met, a chief factor in determining the cost and therefore the price of such work is one to which, we fear, many photographers pay little attention, namely, the standing or overhead charges. Very often the cost of materials is a minor factor relatively to the proportion of these overhead charges which is, or should be, borne by a particular piece of work out of the ordinary. We have referred to competition, but too much importance should not be attached to it, for the two following reasons: that frequently a competing price which is quoted by a photographer who is asked to quote cannot be accepted; and further, if plenty of work is to be had, due importance for the proportion of standing charge will often show that at the competitive price the work is being done at a loss. It may be of service to those who do not have given as much consideration to these charges as should be the case, if we set down a list of eleven different sections of them, which are mentioned in a Canadian journal circulating among retail chemists. They are: 1. rent; 2. light, heat, power and telephone;

3, salaries of owner and assistants; 4, delivery cost; 5, interest on capital; 6, insurance, taxes and subscriptions; 7, bad debts and collection expenses; 8, advertising; 9, depreciation of equipment and stock, repairs and renewals; 10, expenses, such as breakage and spoilage, returned goods, reductions; 11, miscellaneous supplies for offices and workrooms. Costs belonging to all these sections apply equally to the whole turnover for the year, and on the presumption that the total of them and also the total turnover for the previous year are known, the amount which requires to be allotted to a particular job is readily computed. From the actuarial standpoint this is, perhaps, a crude method of describing what should be done; nevertheless, it is a good deal better than the common practice of neglecting "overhead" altogether.

* * *

A Tar Camera. Considering the resources of the English vocabulary, it seems a pity that the word "camera" should be applied to instruments which have nothing to do with photography or even with light. In the current issue of the "Gas Journal" we see described an appliance for the approximate measurement of the quantity of tar in town gas. It is an American device by which a deposit of tar is obtained on a sheet of white paper, and is called a "tar camera" by its inventors or users in the United States. It is, of course, in no sense a camera, but simply a chamber into which the stream of gas is led. We suppose our American friends would justify their appropriation of the word by saying that they are using it in its old literal meaning. But the literal meaning is, if anything, more specialised than that which is associated with photography, and survives only as the name of the legislative chamber in some Latin countries and in the judicial phrase *in camera*. There is really no excuse for misuse of a word which is so firmly rooted in the popular mind, and which, in the present instance, is readily replaceable by "indicator," "tester" or a similar term.

* * *

Goldless Self-Toning Papers. During the last few years a good deal of interest has been taken by German experimenters in the use of selenium and tellurium compounds for the toning of development prints, but a somewhat unexpected application of these substances appears to have been discovered. According to a patent specification of the Dresden firm of Kraft & Steudel, a print-out collodion emulsion containing selenium dioxide or telluric acid, the latter dissolved by means of lithia, yields brownish purple tones when fixed in an acid bath consisting of 5 per cent. hypo and 10 per cent. potassium bi-sulphite. The emulsion is one prepared by addition of silver nitrate, lithium chloride and citric acid to 4 per cent. collodion. The effect of the selenium or tellurium compound is stated to be similar to that of the gold chloride as a constituent of a self-toning emulsion. But, so far as we are aware, nothing is known of the degree of permanence of prints made on papers, in the coating of which the place of gold is taken by such compounds as these of the baser metals.

* * *

Worn Camera Coverings. Judging by the many hand cameras that we have seen the leather or leatherette coverings of which are decidedly the worse for wear, it might be assumed the renovation of such is a more or less difficult job. The reverse is actually the case, and perhaps some of our readers may like to take the hint, when their cameras are at rest during a quiet season, of improving their appearance for the coming fine days. If the covering has only become dull, a good brown polish may be applied with a piece of clean rag, rubbing it well in and giving a final polishing with a clean, dry, fluffless cloth. If the camera has been more or less neglected and its black covering has discoloured, it may be re-blacked with leather dye, obtainable at any saddler's. The dye should be applied with an odd piece of cloth, care being taken not to make the covering too wet, or the glue attaching it to the camera may become loosened. If the dye is not available a black, not blue-black, writing ink may be made to serve. When the black has become thoroughly dry the covering may be given a coat of a good, quick-drying spirit varnish, which will be found to restore much of the original appearance.

FAILURES THAT TEACH.

THE facilities for turning out good work, for which the present-day photographer has to thank the plate and paper makers, have tended to make him less thorough in his methods, and certainly less skilful than were the old wet plate workers. When everyone started from practically the same point, by buying unmixed chemicals and plain glass, any difference in quality could only be attributed to the skill of the worker and the circumstances in which he worked. If his negatives were foggy or his plates were slow, he had to trace the cause of the trouble, and usually gained some valuable information in doing so. There was no opportunity of changing his plate maker with the idea of mending things, so that self-reliance was fostered and success was the direct result of effort.

Many, if not most, of the difficulties which arise would be avoided if a regular course of technical instruction formed the prelude to entering upon a photographic career, but unfortunately only a few are in the happy position of having received such training, so that knowledge must be gained piecemeal as the exigencies of daily work demand it. The first step is the cultivation of the habit of accurate observation. Failing this progress will be slow, and discouragement must inevitably ensue. This may be illustrated by recounting an actual experience. A portrait operator had been troubled by the appearance of semi-transparent patches upon his negatives, especially during hot weather, and attributed them to faulty coating. He thereupon changed his plate maker, and for a time the negatives were perfect, but in the course of a few weeks the trouble reappeared, and he was forced to conclude that the fault lay in the manipulation and not in the manufacture of the plates, and set about discovering the cause. It was found that the plates were perfect when placed in the washing tank after fixing, but on removing them from the water in the morning certain of them bore the disfiguring marks. This pointed to the fact that the gelatine had become partly decomposed and had dissolved in the washing water. The next batch was washed for about an hour and put in the racks the same night, the result being entirely satisfactory. Without the careful observation which noted the stage at which the spots appeared a further change of plates might have been made, and if these had happened to be coated with a very hard emulsion, which withstood the prolonged soaking, two plate makers would have rested under the unfair imputation of issuing faulty materials. It was not long before the knowledge thus gained again became useful. The printing was nearly all done upon gelatino-chloride paper, and a sudden epidemic of fading set in among the prints, even those in the showcases only lasting a few weeks. The photographer at once suspected that the same decomposition which had spoiled his negatives was working havoc among his prints, and a careful examination showed a slight unevenness upon the

glossy surface. The time of washing was curtailed and the trouble did not recur. Here we have a fair example of the value of careful investigation, for it enabled the photographer to use such materials as best suited his purpose without fear of the fatal markings.

All defects are not so pronounced as were those in the foregoing instance. In some cases it is to be feared that they are hardly recognised, but it may safely be concluded that if one's prints do not equal in technical quality those exhibited by the best workers there is a reason for it and that this reason should be discovered. One of the commonest defects at the present time is the wretched colour of sepia-toned bromides. Apparently, many photographers consider it unavoidable, but a little investigation will soon prove the contrary. It may rest with the negative, which may be too flat to yield a tonable print; it may be imperfect washing before toning, the use of a weak sulphide solution, or over-exposure and under-development of the prints themselves. Here it is clearly open to anyone, who feels that his tones are not as good as they might be, to track the defect to its source.

In every branch of photography may this process of observation and rectification be carried out, and in none is it more necessary than in the lighting of the sitter and exposure of the plate. If the print does not give the impression of the sitter as he appeared in the studio, one or the other of these points needs attention. Some photographers have the belief that "Rembrandt" negatives must needs be foggy; no greater error can be made. Others, habitually, under-expose and over-develop their negatives, with the result that by the time the face is printed all detail in dark clothing is buried. To such the advice may be given to study the best work within their reach and to form the resolve to find out wherein their own falls short. The specimen prints issued by plate and paper makers are highly educative, and will do much to point the road to good work to those who wish to follow it. If the road be found too rough, then a friendly hand must be sought, and this will readily be extended by the trade demonstrators, while our own "Answers to Correspondents" column is always at their command.

It is to be feared that the average photographer is not a reading man. If he were to study, and profit by the information which is printed week by week, he would have fewer tribulations. It has been reported upon credible authority that some photographers do not even trouble to read the instructions issued with the materials they buy, much less to follow them.

The investigation of defects should be undertaken with all possible care. Chemicals should be weighed and measured, dishes and apparatus should be clean, the dark-room lamp should be beyond suspicion, and the camera, and particularly the lens, clean and free from dust. Every precaution taken in this way is a step on the road, as it eliminates a certain number of causes of error and leaves a clearer way to tracking down the defect which is to be sought for.

PARIS NOTES.

Aerial Photography and Photo-Surveying.

A REVIVAL of interest in aerial photography has resulted from the exhibition at the seventh Aeronautic Salon, held last November, of equipment for aerial photography and of examples of the extremely fine work done by the various French firms who have taken up this subject. Some new introductions were shown, notable among them two film roll-holders, one taking a hundred 18 × 24 cm. pictures made by M. P. Garnier to the specification of MM. Libman, Galiment and Lenouvel; the other, for 350 exposures of the same size constructed from designs by Captain Paumier by the Puteaux army arsenal. The latter, however, was exhibited only as a non-working model, from which it was impossible to form an opinion of its action. The Cadastral Service of the Liberated Districts showed a Rolland changing box for 150 exposures on 18 × 24 cm. plates, made by the Société Optia, and also a between-lens shutter for a 20-inch f/6 lens, made by the Société d'Optique et de Mécanique de Précision, which firm during the war supplied the bulk of the lenses employed in the Aviation Service. The Cadastral Service also showed in action the camera of H. Roussilhe for the correction of aerial negatives taken with an oblique lens axis. An apparatus for the printing of long bands of film negatives on to continuous bands of bromide paper was shown by the Société Filmographe in the shape of a Prestotype printer of M. L. Lobel, constructed on the same principle as the cinematograph printer of the same inventor and providing the necessary automatic variations in the strength of the printing light for each negative in the film band.

During the period of this exhibition there was opened at the headquarters of aeronautic equipment at Chalais-Meudon, near Paris, an aeronautical museum, which contains a photographic section, small at present, in which are brought together aerial cameras taken from the German army. The museum is open to the public on Thursday and Sunday afternoons.

Stereo-photogrammetry, which up to a few years ago was greatly neglected in France, is now being closely studied. The Société Française de Stereo-topographie, recently formed in Paris on the initiative of M. P. Corbin, who has introduced these methods in France, has made an arrangement with the firm of Zeiss for the application in France and the French colonies of stereoscopic methods of making maps, and in particular for the use of the von Orel stereo-autograph, the latter an apparatus devised by the Austrian Geographic Service for the automatic drawing of maps and of their contour curves.

A French railway engineer, M. J. Prédhumeau, with the aid of a subsidy from the Ministry of Public Works, has set out to obtain equivalent results with a much more simply constructed camera, and has made an experimental model of his "Stereo-topometer," which has given every satisfaction in the course of its first trials.

It may be finally added that another engineer, M. Poivilliers, belonging to the Compagnie Française de Navigation Aerienne, has patented a camera based on both the Bildmesstheodolite of Hugershoff and the von Orel Stereo-autograph for the application of stereo-photogrammetry to aerial photographic negatives.

Cinematography.

An event of great importance in cinematography is the recent introduction of the "Mundial" cinematograph projector of the firm of Continsouza. This apparatus must be said to be not merely an improvement on existing types, but an entirely new and excellent conception. The shutter, which is of truncated conical form, is placed between the condenser and the film. Flicker is absolutely eliminated by the direction and speed of its rotation, as is shown even when the apparatus is run without a film. Wings mounted on the shutter cause it to function as a powerful fan, strongly cooling the film and permitting of any single picture being projected in the ordinary way. The film passes into an absolutely closed

channel, which completely separates it from the mechanism and, moreover, provides an absolute preventive of the film catching fire. If the motor of the projector is stopped, if the fall of the safety cut-off is intentionally prevented and if the shutter is turned in the open position, the film will catch fire, but the combustion is limited to the piece of film contained in the gate and does not even extend to the perforations, so that after such an incident projection is continued when restarting the motor. The efficiency of these arrangements is such that the constructors have obtained from the authorities permission to dispense with the water cell, the use of which has hitherto been compulsory in every cinematograph exhibition.

At one of the recent meetings of the cinematograph section of the French Photographic Society, M. L. Clement, a leading authority on cellulose ethers, gave a very interesting talk on non-flam film of cellulose acetate. The difficulties which some manufacturers have had arise from the random choice of the cellulose acetate. This latter is available not as a single definite substance, but there are several cellulose acetates differing very greatly in their properties according to their source. Varieties which are the best for varnish making are not suitable for film manufacture, and *vice-versâ*. The technical experts should be able to specify the qualities which a cellulose acetate should have in order to fit it for the manufacture of cinema film, and it would be easy for manufacturers to conform to these descriptions. The characteristics of a good cellulose acetate film are very little different from those of a celluloid film, and the resistance of the former to abrasion is greater. Most of the celluloid negative film, moreover, has a coating of cellulose acetate in order to prevent electrical markings.

As a result of this conference a committee has been formed to define the chemical, physical and mechanical properties required in cellulose acetate for cine films, and the technical experts of the cinematograph film manufacturing and producing firms are represented on it. Another committee has also been established in order to endeavour to obtain an international standard for perforations and for the marginal notches indicating the required alterations in the light when printing from negative films.

Colour Photography.

An experiment which would have been very interesting if it had been carried out more strictly and systematically was recently made by the colour photography section of the French Photographic Society. A number of Autochrome plates coated with the same batch of emulsion were exposed under identical conditions (the three plates of each set of three receiving different degrees of exposure) on a still life subject consisting of bronzes, flowers, and fabrics, illuminated by electric light. Each set of three plates was developed by the advocate of a particular method of development. Unfortunately none of these workers were accustomed to the illumination of the dark room in which development was done and, therefore, the results were greatly inferior to those usually obtained by them. It seems, however, that some conclusions can be drawn from this comparative test. For Autochrome plates, the exposure of which has been somewhat cut down, the best results appear to be obtained by the Lumière metoquinone developer. For somewhat fuller exposure the pyro developer recommended on the introduction of the Autochrome plates serves well. It is recognised that this developer is the best for plates which have been kept considerably beyond the date allowed for their use by the makers. Lastly, the diamidophenol developer made acid by an appreciable addition of bisulphite so as to prolong the time of development to about an hour appears to give the best results from Autochromes which have been considerably over-exposed.

M Schitz, one of the most skilful workers of the process, has recently shown some very fine landscapes made in quarter-plate size with a 15-inch lens. The narrow angle of view requires that the foreground should be at least about 150 ft. from the camera, with the result that the atmospheric effect is to soften the colours and to avoid too violent effects. At this small angle also it is usually an easy matter to obtain excellent composition without the inclusion of the sky in the picture, thus eliminating a feature of the landscape which is almost always unsatisfactory in an Autochrome unless it presents striking features.

A New Process of Colour Photography.

M. Leon Didier, inventor of the Pinatype process, has recently been granted a French Patent (No. 524,143 of March 17, 1919) for a new process of colour photography by printing from a negative in complementary colours (*e.g.*, an unreversed Autochrome) on to a sensitive film, or several such films, so that there is formed at each point a colour complementary to that in the negative, and therefore corresponding with that in the subject.

The inventor sets forth as follows the conditions to be fulfilled:—The three series of reactions, each corresponding with the production of a primary colour, should be chemically and optically independent; fixation should be possible for the three sensitive films by a single reagent, or, at any rate, by reagents which can be mixed together.

The leuco compounds of certain dyes alone or in a mixture with other substances are sensitive, particularly to rays complementary to the colour which the compounds assume on exposure to light. For the production of the yellow image other reactions may be employed, taking place only under the influence of the actinic blue and violet rays. Fixing is to be done in a solution of monochloracetic acid, with addition of stanneus chloride.

Stereoscopic Work.

M. G. Potonniée, one of our most enthusiastic searchers of documents relating to the history of photography, has recently drawn attention to two drawings made by J. Chimenti (1554-1640) which are in the Wicar Museum at Lille. These two drawings form a beautifully drawn stereoscopic pair made two centuries before the invention of the stereoscope by Wheatstone.

M. Guérin, maker of the well-known Leroy stereocycle, in collaboration with M. Delens, has recently designed a very compact new model of magazine stereoscope, in which the transparencies are handled with great speed and certainty. Its all-metal construction leaves nothing to be desired as regards mechanical perfection.

Pictorial Photography.

The great success of the competition organised by the "Revue Française de Photographie," particularly in regard to the standard of the work submitted to the judges, denotes a reawakening of pictorial photography in France. Moreover, a Salon of Photography will probably be held in Paris in 1922 under the management of a group of the principal photographic societies in conjunction with the "Revue Française," thus restoring a feature of French photographic activity which has been dormant for nearly ten years. The difficulty in obtaining a suitable place for such an exhibition is likely to limit the number of works which can be shown, but upon however modest a scale the effort is made it is bound to have a highly favourable influence upon the progress of pictorial photography in France, where the high price of photographic requisites has had a strongly deterrent effect upon this branch of the art.

The Constitution of Developers.

A few months ago M. M. Abribat, in a paper before the French Chemical Society, pointed out that he had been able to develop photographic plates by means of products obtained by the action of sulphurous acid on a solution of fuchsine or malachite green. To these solutions, in which M. Abribat admitted the presence of the corresponding leuco bases, carbonate of soda was added at the time of use. Although without any practical interest, this observation had a certain importance, since it represented an exception to the law laid down by MM. Lumière on the chemical constitution of organic

developers. MM. Lumière and Seyewetz, in repeating the experiments, have shown, on one hand, that the method of preparation does not yield the leuco bases, but carbinolic bases, and, on the other hand, that in a pure state neither these compounds nor the leuco bases possess developing properties.

MM. Lumière and Seyewetz have shown at the same time that the images developed with indoxyl or thioindoxyl, according to Homolka, are due to a very different reaction from those which take place in the use of the customary developers, and that such images, whilst very weak, do not contain (in addition to the colouring matter) metallic silver, but most probably silver sub-bromide.

Notes and News.

The Institute of Theoretical and Applied Optics, established in Paris, at 140, Boulevard du Montparnasse for the training of constructors and workpeople in the scientific instrument trade, have just commenced the publication of a monthly journal, "La Revue d'Optique." The director of this Institute is M. Charles Fabry, Professor of Physics in the Sorbonne, to whom the Franklin Institute of Philadelphia recently awarded one of the Franklin Medals for his optical researches, in particular in spectroscopy.

The annual meeting of the French Society of Industrial Chemistry, held in Paris during the second week in October, announced a section devoted to photography. The announcement of the congress, however, was made so late that, for lack of anyone to take part in it, a meeting of this section could not be held. Sir W. Jackson Pope addressed the general congress on the future of the organic chemical industry, and was awarded the gold medal of the Society of Industrial Chemistry.

Several Parisian newspapers recently reprinted an article from the "Times" according to which synchronism of movement and speech in cinematograph projection "had just been discovered." M. Léon Gaumont, who in 1901 solved this problem, with the help of his colleagues, has since perfected it, and has on many occasions given public demonstrations of his Chronophone or Talking Film (notably in 1902 and in 1911 at the French Photographic Society), has naturally been prompted by this announcement to draw attention to his invention. At a meeting of the French Photographic Society on October 28 he again gave a performance of several talking films. The present apparatus is certainly capable of further improvement as regards the quality of the sound and the means of register, but nevertheless it achieves absolutely the automatic synchronisation of a cinematograph and a phonograph.

L. P. Clerc.

THE TRICK OF PHOTOGRAPHING A MAN.

[The "Minutes of Proceedings" of the thirty-ninth annual Convention of the Photographers' Association of America, held at Buffalo last summer, have been published as a handsome volume of over 200 pages, edited by the general secretary of the Association, Mr. J. C. Abel. In addition to containing twenty-one supplemental reproductions of American professional portraiture, it brings together an almost verbatim report of the proceedings at the many meetings which were held. Owing to the fact that demonstration went hand-in-hand with talk in the case of most of the fixtures, it is not possible usefully to reprint addresses which very plainly had a great value for those who heard them. But a discourse of Mr. Pirie MacDonald's, while dealing in an eminently practical way with the conditions of studio portraiture, is of such a form that a place can be advantageously given to it in our pages. Mr. MacDonald had much to say on lighting, but his chief theme was the establishment of such relations of common interest between the photographer and his sitter which make for successful character rendering in the resulting portraits. His talk on this congenial topic was flavoured with much characteristic humour.]

There is unrest on the part of everybody at the moment, in the matter of equipment. Everybody seems to be hunting around and wondering whether it isn't a solution for all the troubles to have new and different equipment, like the man who went to see the doctor. He had been to this doctor many times, and the doctor said to him, when he came in, "What's the matter with you now?" and he replied, "Well, ye see Doc., I don't know, but what's new?" (Laughter.) And so it is in the matter of equipment. It doesn't seem to make much difference to people what it is, so long as it's new. They want a change. It's a very healthy symptom.

But it is true, as people who have been doing home portraiture have proved, that it doesn't make an awful lot of difference what the apparatus is, what the light is, for example, so long as you have plenty of it: it is absolutely necessary that you have plenty of it, but plenty of it for the particular purpose. If one is going to make a large group, of course, you have got to have an illuminant that will cover a large group. If one is going to make a single figure you have got to have the right light for a single figure, or the head.

In the old days we put up a light that would make a picture of forty people at once, and then we became accustomed to using a light adapted to the making of forty heads for the making of one head, and wondered what was the matter with the one head, and so it is particularly with the electric light. You have got to have a light that is adapted to the purpose for which it is intended, and I claim that a person is very ill advised who puts in a light which will do four times—eight times—twenty times as much as they need, and work with the handicap of an uncontrollable light. A principle in electric lighting is that almost any light will answer if you are going to make a single figure, provided the light is adapted to the room in which you are working, making pictures only of heads—there isn't any reason why your room should be more than 6 ft. wide and perhaps 6 or 7 ft. high, so that you may utilise the natural reflex of that light, in order that the direction of the light as it comes immediately from the source, may be felt as direction in a perfectly and properly rounded picture, whereas, if you were to take that same illuminant, whatever it be, and put it in this hall, with all the lights turned out, as you know, it would be a very inadequate affair.

An illustration in the particular case, is this: If one were to take a little candy box, that is perfectly white on the inside, and would put a little doll inside it, and light a match and put it through a hole into the box, you could make a photograph of that mannikin like a flash. You might take that match at midnight here in this hall and put it as close to the human face as you wanted to and you couldn't by any possibility get an exposure, except perhaps at the point of the match. The keeping of all of the light of the match in the box is the trick. Almost all of the light, in the case of this hall at midnight, would be dissipated in the surrounding dark.

And so it is in the case of making pictures of children. Mr. Core and I have talked the matter over many times, and we have finally come to the conclusion that in order to make pictures of children rapidly, in a fixed studio, an ideal arrangement would be something like this: We will imagine a piano box, such as an upright piano comes in,

and we put it up on a little platform with a set of steps leading up to it, and we would put one light—anything you like—so that all the light is contained in that box. Make your side walls and back in a light key and put a little shade forward, so that even what light might go out at the top would be sent back, and you can make pictures so rapidly and so thoroughly timed and balanced that the hard work of making children's pictures would be a joke. The bread-and-butter pictures that will serve every time, dead sure—can be made right off, and then if you have a lot of money and a lot of time, you can take the child into a dark room as big as this, and you can make all of the high art you like to amuse yourself. But bear in mind that those things that are fully illuminated and made so rapidly that you have the heart of the youngster in his face, they are the bread-and-butter pictures; they are the things the people want.

In handling light you must always hark back to fundamentals. There are to-day in this profession, not here in New York alone, but all over the world, a set of people who put things across because there is a certain proportion of the public that is looking for novelty and will buy anything. The girls on the street to-day, beautifully gowned, showing perhaps a little ankle, would give up all of that snappy look when someone brings out a gown that covers even the ankle, if it is supposed to be new. And it is the same way with photographs There is a clientèle for every freak. They say that in New York you can sell anything, but it is so in the smallest town in Ohio. You can sell anything. You cannot sell it, perhaps, in volume enough, but you can sell anything.

But we are not of the kind of people who make pictures as some painters do, after they have muddled along and finally finished the thing, they have a devil of a job finding a name for it. That isn't the kind of stuff we are supposed to make. We are professionals. We are supposed to know what we are going to make and proceed to make it.

In the matter of light, fundamentals are necessary. There is a formula of light—some of you youngsters are very apt to say, "Formula of light; there shall be no formula of light, we ought to make pictures anywhere, anyway." But there is a formula of light that has been passed down through all the good portraits. There is one way that you do get projection; there is one angle, one type of volume that all of the painters have used, and are using to-day, and the fundamental is to get your face into projection that will revive the memory of the person who sees it, and if they remember the person that was photographed and not the photographer who is trying to put on airs, that is the test.

Therefore it is necessary, in the handling of light, wherever the light may be, wherever its source, to have such a light that you can project that face in the formula that the painters have used these three or four hundred years. It must, in order to get that projection, be from a single source (and there are some people in the audience who will say "Ha, ha! he is stepping into a trap"), but I have thought that out carefully, and that it be done in the most absolutely simple manner possible. The light must be merely the exposing element, that which makes it possible for the eye of one person to see on an otherwise blank piece of paper that which stimulates his memory. It must bring about the utmost projection as governed by the necessity in the case—the necessity in the case being the type of person that you are representing, stronger in some cases, less strong in others. If it is not done so that projection is an absolute, dead-sure thing, you are not going to make the pictures that will do the work that you intend them to do, which is satisfying the people that you are selling goods to.

Some of you will say, "Why is it that you have played so much with the double source of light?" You will find that there never was a picture that was made in my studio even with a double source of light, but that had originally, and, taking out the secondary light, projection, absolutely and completely done first, and then the secondary source added for reasons that seemed to justify its use.

The reason I am explaining this at this length is that there has been an unfortunate tendency on the part of photographers, myself among them, to see something that has attracted in the work of another man, and literally copy it. Educationally, it is a good thing to see whether you can do it, but you have got to know the reason underneath it before it is going to be of definite and lasting value. Every now and then we find a person of such indeterminate arrangement of features that if you were to set them down with a light which merely projected their features it might not be highly interesting, but if you take your regular formula of light and soften it down with the projection still there, but so soft as to be even less distinctive, and then you find that the man has one corking good line, say, down his nose, which is in keeping with a point in his character, it will shape the things up and make folks say, entirely aside from the work of the man who has done it, "an interesting personality." I claim that is a legitimate purpose for a double light.

I had, a little while ago, a man who was unfortunate all through the lower part of the face—a mighty strong person, and there are many strong people who are too strong of the animal to be pleasant. They have done things because what mind they did have was backed by a body that permitted them to go through and do things even though it caused them physical pain, over-work, over-hours, over-everything that most people shirk, but they had the body that was able to push through their mind and that shows in the lower part of the face. He had heavy lips, an over-sized chin, a bad nose—too bread at the base—animal—but the man was an interesting man. He had done things, and was entitled to be known by the world as a person of distinction. If I had lighted him in the old formula, in the even sort of way, I wouldn't have given that man his proper place in the world. But! In connection with all of this he had a magnificent forehead. He had hair that grew down in a vigorous sort of way, well over the forehead, with an opening here and there, and I put the finger of light to his forehead in order to show that he had mental capacity. But bear in mind that you mustn't ever use a double light until you have demonstrated one thing first—the portrayal of the man in just and true projection.

There was a man named James Inglis (a lot of you don't remember him, some of the older fellows do), and we had a tumultuous Scot, named Dundas Todd, and in his turbulent way he had to find something to devote his energy to, and he was very glad to find that there was a man named Inglis who had been doing a thing or two in the way he thought was the proper way to do it, and he made quite a god of Inglis. The only reason that Inglis was entitled to a saintship was that, with persistence of the Scot, he had acquired the idea of this simple old projecting light, and he had never let go of it for one minute, and, with the persistence of the Scot, he rammed it down our throats until a lot of us, then younger men, side-stepped him; but Dundas said, "No, ye'll not get away so easily as that, and I'm here, I'll make ye take it!" And he did; he wrote a book on it, and the result is that Inglis to-day is the father of most of the legitimate portraiture of America.

He was a Scot of an unusual kind. My father was a Scot, but alongside of Inglis, even with his bit of doggedness and tenacity, he was a plaything, he was a Dresden china doll. Inglis was the kind that they made the John Knoxes out of; he was the kind that made that old type of Presbyterians who said, "It doesn't make a particle of difference who you are, you're goin' to Hell. That's the kind of material he was made of, and one day, thirty years ago or so, or perhaps a little longer, he came into my studio in Albany and he was showing a little formula of paper, a really choice bit of glossy emulsion paper, and we were making albumens at that time, but we didn't want to make paper, but told him if he would make it we would buy some. He said, "I'll sell the formula, but I'll not make the paper, and you'll have your own troubles with it." And he sold the formula. I, with the confidence of youth, brought out three

of my pictures. I remember one of them distinctly. They were things that I was sure were good. At any rate, they were such an advance on what I had been making that I was distinctly proud of them, and carefully slipped them into his hand. He looked at them with those bushy brows of his, one at a time, and he said, "Who made them?" With due and proper modesty I said, "Why, I did," and he said, "Never tell anyone that ye made them. They are bad—they are bad, man." And as I see it now, they were—the dear man was right. They were made following a trick, the trick of a man that I had observed and admired. They were made without basic knowledge. They were not made with projection, they were made to show how smart I was, not the value of the person I portrayed, and he thereupon gave me a lecture on the validity of lighting which will produce projection in a proper and orderly fashion so that the nose stands ahead of the forehead; so that the forehead stands ahead of the cheek, so that the cheek stands ahead of the ear. There is only one formula for that. James Inglis was right.

I have said these last few words only in order to show you that it is my firm and persistent belief that tricks that cover up your otherwise bad workmanship won't get you through. You mustn't rely on tricks, you have got to make the legitimate. Your customers want it. Bear in mind that the minute that they commence deeply objecting to things, you may know there is something wrong about the pictures. It doesn't pay to make any difference whether you know that they could pass the jury of the P.A. of A., the purpose is to please the customer, and there is something wrong about them if you have not pleased the people you are taking the money from.

Every now and again somebody says, "But about these lenses. The old-fashioned sharp lenses don't please me any more. These softer types of lenses please me much more."

Ah, yes—good! You have moved on! You have come to realise the fact that the human eye does not see the human face as the old type of lens, the German type of lens—the English type of lens showed it. The human eye doesn't see faces that way, unless you are unfortunate and have a bad set of eyes and have gone to an optician who, in order to sell you a more expensive pair of glasses, has given you something abnormally strong—stronger than you ought to have, otherwise you cannot see a human face made up of a multiplicity of detail, such as the old type of lenses set down. The minutia of the human face is not observed by the eye in the way that the old lenses did it. But!—the public became accustomed to it, and you are still selling to the public, and you have got to be careful.

Suppose, for example, you were to go to a restaurant, and you were to find yourself served with a dish surrounded by ice—a little bit of a dish that cost you a dollar and a quarter—and you spread it on the bread, and you had a little bottle of what used to be, but ain't no more, and you found that there was a something in caviare that was remarkably nice, and then you wanted to feed your family, so you went out and bought a hundred dollars' worth of it and fed them only caviare! It is exactly the same way with feeding the public a too soft type of picture. The dear tummies won't stand it!

There is quality in the soft focus lens that is the right quality: it presents the projection of a human face in the fluid manner that the human eye sees a face, and not in the minutia as the old lens saw it, but be a little bit careful of your customers. Bear in mind that Inglis could sell me that formula or not: if he did not, he could take it to someone else, but you are in one town, and you have got to keep solid with those people *all* the time. Lead them along a little bit, break them into the idea that this is infinitely better than what the old type of lens presented, but be *careful* of thrusting things down people's throats.

There is little in the way of material equipment but that you have probably got at home or could go out and buy in the hall. I was thinking, though, last night, and I am going to put it in your minds, because the minds of so many people as we have here, working on one thing, may develop something. Do you realise that there is no artificial proof-printing apparatus in America that is worth a snap. You cannot print fast enough and soft enough at the same time with any piece of apparatus we have got. There aren't any of them adequate to the purpose. The ideal thing would be this: Something that would hold ten, fifteen or twenty, eight by tens, so that you could buy four or five of them, and if you only had ten proofs to make, use one; or if you had twenty, turn on another, or a third, and so on.

Now in the matter of the making of portraits of people, the great thing is to know what you want. The light that you have is in all probability more or less adequate to the demand that you have, but you have got to find out what you want to do.

There was a chap over here named Carpentier who proved that it doesn't make much difference how fine your punch is if you don't know how to use it. So it is with apparatus. You can buy all the things that are here, and if you don't know how to use them they are not worth much to you.

A man came to me three or four years ago, and he said: "Do you have trouble with your assistants getting tired along in the afternoon?"

I said, "Are you talking about something new?"

He said, "Yes."

"No," said I, "I haven't any new problem of that kind." I told him that it had been with me for years, and he said, "I have here a salve, and if you give a box of it to each of your men who have to stand on their feet all day and tell them to rub their legs with it, it would relieve them, and they would immediately get energetic, and the afternoons would be as productive as the mornings."

I said, "Say, son, have you got anything I can rub on their heads?" (Laughter.)

That reminds me of a story—the last was not a story.

There was a little store in the village, and the drummers all used to drop in, and there was an old darky who sat by the stove all the time. One day a man, pretty apruced up, came in and sat down. He lit a cigarette, and seemed to be quite energetic, and the old coon said to him:

"Say, boss, is you-all a commercial traveller?"

"Why, yes, I'm a commercial traveller," was the reply.

"Well, what you-all sellin'," asked the darky.

"I? I'm selling brains," the fellow told him.

"Say," he said, "Boss, you'se de fust travellin' salesman ever come through this place ain't carried no samples." (Laughter.)

You have got to be careful about that. There are too many photographers who are spending too much time learning little tricks that they are able to do mechanically, without thinking. They do them over and over so many times that—Mrs. Jones comes in, and they sit her down here, that is No. 1. Then they tell her to stand over there, that is No. 2. And because they have to have a No. 3, they sit her down here, and bingo!—out goes Mrs. Jones; and, if she is lucky, she draws what she wants. The photographer forgets that it isn't a picture of this outside of a person's face that is wanted. It is something else.

Now what is it we want? What we want is intimacy. There was a dear old man twenty years ago who used to bore me to death, and if he were alive now I'd apologise to him most deeply. His name was Dabbs, and he was from Pittsburgh. He threw a particular hook into me, but I guess he rather thought I was the kind of a person that needed it, and he used to sidle up to me every time I went to a convention and tell me that there was one thing he tried more than anything else to get—said he didn't give a damn about anything else—if he could only get expression. But he told me that some thirty or forty various times under some thirty or forty various circumstances, and I got pretty tired of it. I would take him out and get him a drink, two or three quick ones, so he wouldn't tell it to me again, but the faster he drank the more he told it to me. He said, "You have got to be careful about that. You are making beautiful pictures.

but I don't give a damn how beautiful they are if they don't have expression."

After awhile—after poor old Dabbsy had gone on (the people we owe most to somehow or other get away before we are able to tell them how much we owe them), I seemed to say automatically: "Expression is the thing." And then, after another while, I became conscious, and I said to myself, "Expression! Certainly; but what kind of expression?"

What is the thing that we have got to get into those portraits in order to have them of real value?

I finally determined that the idea was *intimacy*. Suppose you said, "Now while I am making this exposure I wish you would be so good as to observe the edge of that piece of wood!" (Laughter.) Now the picture is on the wall, and the person that loves the subject goes to the picture for sympathy, and only to find that the subject is looking at the edge of a piece of wood!

No, friends! There is something else. Intimacy! Intimacy—the kind of expression that a person gives a person they have respect for, and love for, and if you go through with your game, one, two, three, "good-day Mrs. Jones," they are not going to have "intimacy." You might as well have a towel on your arm and serve frappe bouillion.

You have got to get intimacy (and like Dabbsy I say it again)—you have got to get intimacy on the part of our sitter if you are going to have pictures worth making, worth your taking the money for.

Every now and again somebody comes in and says, "Mr. MacDonald, I just don't like them." I look at them from the point of view of the workmanship and they seem pretty good to me, and I say, "What is the matter with them?" and if by any chance they say "The man in them looks as though he didn't like me," or words to that effect, get rid of them! I get them out of my way and say, "Now you send him to me and we will get him so that he really does like you," and we will start all over again from the beginning.

"Yes, but Mr. MacDonald, I don't know that I can spend all that money again," and my answer is, "It isn't any of your business. That is my business. Send him to me."

Intimacy, friends, is the only thing that is of any value at all in a portrait

Intimacy—how are you going to get it? I happen to be fortunate. I happened to be born with a father who was the worst business man in the world. He was an absolute failure, from the point of view of money-making, but a charming soul, otherwise, so that, when I was eleven years old I had to go to work in an iron foundry. I have never been to school since. I don't know a lot of things a lot of people know, but I woke up to the fact that it was necessary that I know some of the things other people knew in order that they might meet me on terms of intimacy, and I went after it a bit at a time. There isn't anybody here that is as handicapped as I was at the time of which I speak.

How many people here know what is in the mind of the British people in regard to the Irish question? How many are able to turn and see the minds of the Irish people? Here we are in America, neutral, except that we naturally have a sympathy. We ought to have information, and nine out of ten of you don't know anything about it.

There is a book that was published a little while ago that created a furore all over the literary world, written by H. G. Wells, called "An Outline of History." I know H. G. Wells. I spent two weeks with him last summer. I never quite sensed him. There was something about him I hadn't got hold of. But for his "Outline of History" I take off my hat, and I have found that, having read it, a lot of people have a point of contact with me. It is a book that has caused a great deal of controversy, and has enlarged my opportunity for intimacy.

Every once in a while a physician comes in, and they are all interested in the anti-toxin idea. I had to find something out about anti-toxins because the darn things came up so often, and I know something about anti-toxin.

The other night I met a man working in a brass company in Bridgport, and found that there is a trolley wire which will five times outwear any solid copper trolley wire in the world. I know something about it now, and there is going to be a man come in some day who will talk about wire, and I am going to say, "Did you ever hear about that phono-electric?"

A while ago there was a man from Alabama and he was the entire smear—The Number-One-Topside-High-Joss of the town, and his wife confided in me. "Now we have got to have a picture of him. He has endowed the hospital and we need a good one. We have had some taken, but somehow or other they don't look like him." He came in and was pretty nearly as hard-boiled as they make them. He was one of that kind that you could put in a nut cracker and would fracture the cracker. I talked to him about the shows, and he had seen three or four and hadn't an idea. I talked to him about novels—he never read them. I talked to him about the Volstead question, and he didn't give a damn, never drank anyhow. Finally, he dropped a word, and I said to myself, "Ha, ha, in all probability he hasn't had much more fundamental education than I have. We will stop this high-brow stuff, and I said something about foundries, and he asked, "What do you know about a foundry," and I said, "Why, I was brought up in a snap-shop. The first job I ever had was shaking the stuff out of the flasks, putting them in a nail keg, and then hoisting it up on my shoulder and carrying it down and dumping them in a mill."

"My God," he said, "why, that's the first job I ever had."

It would be indelicate to mention in what amount we separated the man from his money, and not being of a boastful nature I shan't. But he needed a lot more things than they had originally planned they wanted. I discovered a great many uses for photographs that even his dear wife had never realised!

There is one thing, however, you have got to be rather a bit careful in this matter of intimacy. Two little girls came to a gate and there was a dog inside. They had to get across to the house for tea or something, and finally, after discussion, one of them decided that the thing to do was to walk right in as though they weren't afraid of the dog, and then he wouldn't bother them. But the other one, being of a kind and considerate nature, said, "But wouldn't that be deceiving the dog?" (Laughter.) And you have got to be awfully careful about deceiving the dog, because if the dog gets the idea that you are deceiving him it is all off with intimacy. The best you get is an imitation, and that doesn't sell very well.

Seriously; you have got to get down to the idea that an artist in our line has got to be a well-informed and well-balanced person. If you are down near Wall Street, you have got to know the market. You can't be a plagued fool and talk to the man about the kind of dresses the man's wife ought or ought not to wear. You have got to talk to him about something he knows about. If you don't you aren't going to get him to come up.

You have got to get to work to-day, and read your newspapers intelligently—and not look them over to find out whether Mrs. Stillman and Fred—or any of that kind of stuff—you have got to find out what the world is thinking about to-day; what the world is feeling to-day. You have got to know something about what is going on in your town. It is a mill town—what is going on in those mills? You can find out. If you are living in Detroit, find out what Henry Ford is doing—a constant topic of conversation—always have something to talk about if you follow Henry Ford. And if you don't educate yourself in that way you are not going to be doing your duty to yourself or to your clients.

Many people look on a photographer as a beach-combing tintyper or as an intelligent crafty artsman. You know the stripe that makes these soft and nebulous pictures that nobody understands, and nobody would care about if they could; you have got to be recognised as a solid man of worth, because you have brains in your head and you use them (Applause.)

In conclusion, I want to say: In the matter of intimacy

you have not only got to have things in your head—if you don't have a heart, you don't stand a chance. You have got to regard the man who is opposite you as a somebody, not merely a cheque-book, but somebody like you, if you are going to make pictures of that man's face that are worth while. You have got to have sympathy in order to have intimacy.

Now I make pictures of men I like, and you can't like a man without his liking you in some degree. You have got to have genuine sympathy for people. You have got to make up your mind that every man, woman or child that comes in has something in him or her that you will like and then hunt for it. The things you don't like, forget about—put to one side—see only the good things—really like them. If you find that you are only doing it in a "sort of way," merely finding those things that appear to be unpleasant cut your job and go away and clean your heart out, and come back fresh and new and be prepared to like people. Once you get so that you really like people—you won't bother about anything at all except the work that you have got to-day, and you will thank God in your heart as I am thanking God, that I am here, and that you have let me talk to you as long as you have.

PIRIE MACDONALD.

FORTHCOMING EXHIBITIONS.

January 11 to 27.—Camera Portraits, entitled "Men of Mark," by Walter Stoneman, at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1.

January 21 to February 4.—Partick Camera Club. Particulars from the Hon. Secretary, James Whyte, 51a, Peel Street, Partick, Glasgow.

February 7 to 11.—Sheffield Photographic Society. Latest date for entries, January 21. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield.

February 11 to 25.—Scottish Photographic Salon. Latest dates, entry forms, January 23; exhibits, January 31. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Latest date for entries, January 30. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Latest dates, entry forms, February 4; exhibits, February 9. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Latest dates: Entry forms, February 8; exhibits, February 22. Particulars from the Hon. Secretary, P. Dorker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beanval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications December 28 to 31:—

SHUTTER MECHANISM.—No. 35,085. Shutter control mechanism for folding cameras. W. F. C. Devlin.

PROJECTION APPARATUS.—Nos. 34,341 and 34,842. Light-projection apparatus for optical projection lanterns, etc. P. E. Correll.

PROJECTION SCREENS.—No. 34,879. Optical projection screens. R. van B. Schele.

CINEMATOGRAPHY.—No. 35,032. Cinematograph projection. Stereo Kinema Syndicate, Ltd.

CINEMATOGRAPHY.—No. 35,136. Projection of cinematograph films. W. H. B. Streatfeild.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH CAMERA FINDERS.—No. 145,656 (July 23, 1918). The camera, which is capable of being steadily moved vertically when being operated, is fitted with a finder eye-piece, and a

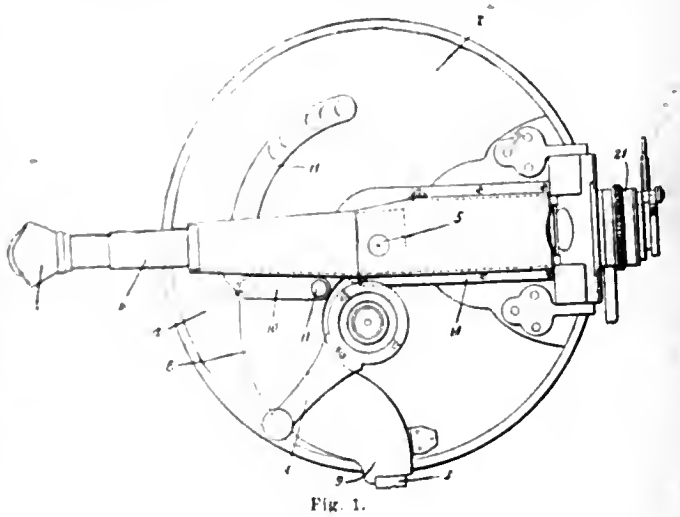

Fig. 1.

finder lens of the same character as the main objective, and the tube for the rays between the two is so constructed that the lens-carrying portion is movable with respect to the stationary eye-piece, the latter part being provided with a fixed and an adjustable prism whereby the light-rays through the finder lens will at all times be directed to the eye, in all positions of the camera and to whatever point the objective lens may be directed.

By this means any object moving through space may be readily kept in proper position in the field of the finder, and in a corresponding position in the photographic field, with the least possible difficulty, as the eye-piece is subjected to but slight movement and that horizontally only, and the object, whether overhead or below the operator, may be kept in view without any material change in the latter's position.

Fig. 1 illustrates the camera and the manner of attaching the finder. 2 is the cylindrical camera casing which is movable in both a vertical and a horizontal plane with reference to the fixed support which may be regarded as indicated by the post 3. The handle for feeding the film and operating the camera is marked 4.

At the point 5 is pivoted concentrically with the axis of the camera a sight tube 6 having a suitable eye-piece 7. This tube is rigid with a plate 8 which has its free end 9 in contact with the part 3 at any part of the camera stand or base so that it cannot he further turned in that direction.

10 is a resilient plate secured to the part 8 at 11 and having a stud 12 passing through a corresponding hole in plate 8 and engaging with semi-circular depressions in an arc-shaped bar 13, secured to the side of the camera and constituting a ratchet and forming a semi-positive lock therewith.

The lens-carrying portion of the finder attachment 14 (see figs. 2 and 3) is secured to the side of the camera and extends

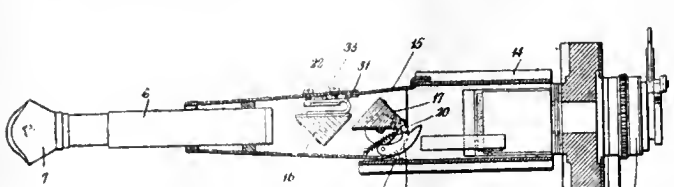

Fig. 2.

under the other part and is connected to its upper side by a strip of leather 15, so that when the camera is turned in a vertical plane the angle between the two parts of the finder may be varied at will. This is clearly shown in the drawings.

In the rear part of the sight tube 6 is a fixed prism 16, and supported concentrically with the pivotal point 5 is a revoluble prism 17. To one side of the tube 6 is pivoted a cam lever 18, having a rounded surface that bears upon a stud or pin 19 set in the lens-carrying tube 14, and the upper edge of this lever is fashioned to engage with a pin 20 on the support for prism 17, so that as the part 14 moves relatively to the part 6 the prism 17 is turned about its axis to receive the light-rays from the finder lens 21, and direct them at changing angles through the prism 16 and directly to the eye-piece 7 or axially through the section 6 of the finder tube. The stationary prism is preferably carried by an arm 31 attached to an opaque backing 31^1 which in turn is mounted on the side wall of section 6 by four screws 32 passing through the latter and holding a rounded point 33 against the normally stationary part of the tube 6. This accords a ready and convenient means of adjusting the prism to exactly its proper position.

In use, the normal position of the camera and its attachment is shown in fig. 1. The two parts of the sight tube are in alignment, and the plate 8 in engagement with the part 3. These

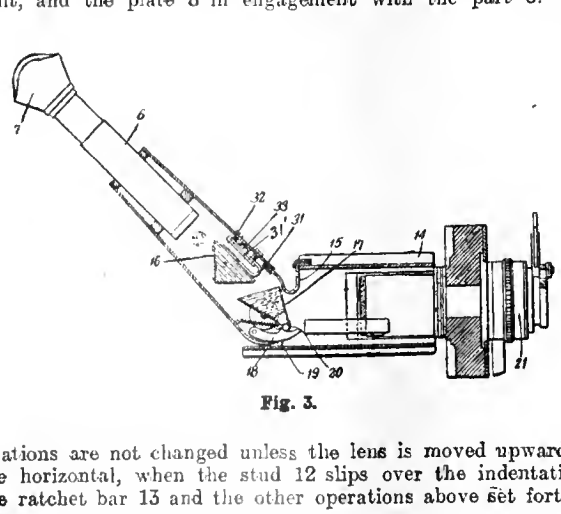

Fig. 3.

relations are not changed unless the lens is moved upward from the horizontal, when the stud 12 slips over the indentations in the ratchet bar 13 and the other operations above set forth take place.

If the operator is in an elevated position and desires to photograph objects below or beneath him, he turns the camera through a great or less angle and brings the eye-piece as near the vertical as need be, when it will be locked by the stud 12 against downward movement. By then looking down into the eye-piece an object may be followed from a point nearly vertically below to a point horizontally in front, as the necessary movement of the camera is permitted by the ratchet bar 13 without any change in the position of the eye-piece. If the camera is to be moved in the direction which is normally opposed by the ratchet 13, the stud 12 may be lifted to prevent this to be done without difficulty.

A camera equipped with the invention is capable of use under all imaginable conditions with the minimum of trouble and difficulty. An aeroplane may be photographed in flight from a trench, a street scene may be photographed from a window, or similar operations performed without requiring the operator to assume inconvenient and difficult attitudes for the purpose of keeping the object photographed in the centre of the field of vision.—Carl Ethan Akeley, 244, West 59th Street, New York.

All-Metal Roll-Film Spools.—No. 172,399 (September 3, 1920). Hitherto it has been usual to slot the roller of a spool for the reception of the tab on the end of the film wound thereon. The object of the present invention is to provide a more effective means for receiving the tab, so that it will facilitate the insertion of the tab, and will then offer a firm resistance to its withdrawal during winding or unwinding, while permitting of a free withdrawal of the tab when the film has been unwound completely.

According to the invention the metal roller is provided with one or two inturned lips along the slot. The roller is preferably formed by rolling sheet metal into a cylindrical form so that the adjacent edges of the seam are interlocked, except where the metal is cut to form the slot, the edges along the slot in one form both being turned inwards so that they form a V-shaped recess. The edges may touch one another at the bottom of the recess. They thereby form salient grippers which tend to grip the tab of the film inserted between them, especially when it is wound on the roller, while they enable the tab to be withdrawn freely when the film is completely unwound and the tab is pulled radially out of the slot. The two lips need not be radial, but may be set or inclined towards one side especially when the roller is intended to be mounted on a spindle.

The form of the lip, or of each lip when two are used, may be variously modified, for instance, it may be straight or curved or straight for a portion of its depth and curved for the remainder, so as to render it more resilient. One lip may be curved and the other straight. In a simple form a lip may be formed by simply extending one edge of the slot under the other.

The roller is preferably provided with flanges which are placed on the ends of the roller which are first beaded, and then spun over, plugs of stamped sheet metal being forced into the ends of the roller to lock the flanges.—William George Temple and James Henry Wilkes, both of 80, Malden Road, Kentish Town, London, N.W.5.

Cinematograph Projection Screens.—No. 170,739 (January 15, 1921). A screen of canvas is mounted on an open quadrilateral frame provided along each side with a projecting flange over which the material is stretched. The flanges are arc shaped, to present a convex supporting surface for the screen material whereby concavity is imparted to the latter. Adjustable tension devices are provided to enable the material to be stretched to the desired degree.

The stretching of the canvas is conveniently effected by means of a series of screw tensioning devices in the form of turnbuckles each connected at one end to a frame member and at the other end to the sides of the flange, whereby the flanges may be tilted outwards or transversely of their length about their bases and thus stretch the canvas.—James Styles, 11, King's Drive, Whitley Bay, Northumberland.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Kristal.—No. B416,794. Photographic dry plates. The Let Photo Materials Co. (1905), Ltd., 1, Crutched Friars, London E.C.3, photographic manufacturers July 8, 1921.

Iko.—No. 418,227. Photographic plates and films included i Class 1. Ilford, Ltd., Britannia Works, Roden Street, Ilford Essex, manufacturers of photographic plates, paper and films September 2. 1921.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 10, the President, Dr. G. H. Rodman, in the chair.

A discussion, arranged by the Scientific and Technical Group, on the desirability of a numerical rating of contrast for commercial printing papers, was opened with a paper by Dr. B. T. J. Glover, read in the unavoidable absence of the author, through influenza, by Mr. K. C. D. Hickman.

Dr. Glover considered the question on the one hand from the sensitometric standpoint, and on the other in respect to the commercial practicability of publishing constants of a printing paper which might be determined as a measure of contrast. He set forth the four measurements which might be made of a printing paper in order to provide information of its contrast quality in printing, viz., gamma infinity, exposure range, maximum density and "rendering power," the last named being the constant representing the straight line portion of the H and D curve of a paper. By exposure range he meant the ratio of the two exposures, one of which gives the lightest tone on the paper and the other the deepest black of which the paper is capable.

He pointed out that no one of these constants is sufficiently descriptive of the contrast quality of a paper. Moreover, the exposure scale and maximum black yielded by a paper were subject to irregular variation in practice according to the character of the negative. He regarded the gamma infinity as an essential constant. This and the exposure scale were the minimum requirements for the indication of contrast quality, the other two being optional. But the measurements were not easy to make, and it was to be feared that they would be considerably altered as the paper progressed with keeping towards staleness. Moreover, it was possible that competitive advertising would impair the accuracy of any measurements.

Dr Glover put forward with considerable diffidence the alternative scheme of establishing a multiple test negative consisting of several negatives of different degrees of contrast. A print (on the paper) made from this negative would perhaps mark one or other of six degrees of contrast sufficiently sharply to allow of a paper being given one or other of six contrast markings. Whatever method was adopted it was necessary that the indication should represent development of the paper to gamma infinity. Such a marking would then, perhaps, contribute to the more thorough development of papers, and, further, would show the advantage to be gained by development on the factorial system.

A contribution to the discussion by Mr. J. R. Hall, of Liverpool who also was unable to be present, was read by Mr. Bloch. Mr. Hall expressed the view of the quantity producer of photographs, as, for example, in the printing of amateurs' negatives, and maintained that a numerical rating of printing papers for contrast was highly desirable.

Mr. J. C. Warburg thought it possible that manufacturers could agree to apply uniformly certain figures or symbols to papers possessing definite degrees of contrast.

Mr. F. F. Renwick further emphasised the points raised by Dr. Glover. There was, he said, no technical or commercial objection to stating the exposure range of a paper. But in the absence of the additional information respecting the gamma of the paper, the statement of exposure range would be misleading as a means of judging from the published figures the degree of contrast which prints would yield. In illustration of this, he showed two prints of very different contrast made from the same negative and on papers having identical exposure ranges but differing in their gammas. Mr. Crossley, Dr. Slater Price, and Mr. Hickman further took part in the discussion, the latter endeavouring to harmonise the views of users and manufacturers, and suggesting a qualitative indication of contrast quality which the latter might give.

Mr. A. F. Keeling then gave a demonstration of the properties of ultra-violet light, and showed the remarkable fluorescence of a number of substances including ordinary vaseline. He incidentally illustrated the strong absorption of ultra violet rays by aesculine and the new Ilford Aviol dye.

At a late hour Mr. Murriott, of the General Electric Company, gave a description and demonstration of a new projector type of gas-filled Osram lamp. This was a very recent development of the G.E.C., and was being made in a series of powers and for a range of voltages by use of a suitable resistance. The makers had

specially considered the life of the lamp, which was about 500 hours. The lamp is of upright tubular pattern, having the filament arranged either as a flat grid or in shallow crescent or bunch form. As demonstrated, a small lamp gave an excellently even and brilliant projection, and evidently was very well adapted for both enlarging and lantern work. The price of the model shown was 12s. 6d., exclusive of the necessary fitting and resistance.

Votes of thanks were accorded to authors, readers and demonstrators who had contributed to the proceedings

CROYDON CAMERA CLUB.

Mr. C. M. Thomas, M.A., lectured on "Chemical Methods in Photography," starting with the French Revolution of the 18th Century, a very heady time. The administration originated the present metric system, and it was not its fault that the one-ten-millionth of the earth's quadrant from the North Pole to the Equator has turned out to be not exactly coincident with the metre, with all apologies to the genial lecturer, who seemed to impute the contrary.

In a very clear and interesting way he then dealt with the metric system, and contrasted it with English weights and measures, which were referred to most unkindly. Still it was comforting to hear that they are good enough for photographers, if the inference be not altogether flattering to the fraternity.

The formula for chromium intensification given in the current "B.J. Almanac" was given as an admirable example of what to avoid. The original formula was far better, as the proportions were obvious at a glance, and useful as a basis for making up working solutions. It must be recorded, even if it reduces the sale of future Almanacs to the vanishing point, that the members generally agreed with Mr. Thomas.

He next dealt with the convenient "10 per cent." solutions, which he said are compounded by dissolving one ounce (the despised "avoir.") of the chemical in water to make nine fluid ounces. Under severe cross-examination he confessed a further 55 minims ought to be added for complete and satisfying accuracy.

This statement started a most amusing rumpus, the dear old 10 per cent. controversy cropping up once again more alive than ever. Mr. Jobling was scandalised and shocked at the idea of the above proportions being considered a 10 per cent. solution, and advanced cogent reasons to the contrary. Observing the "office boy" all smiles, he pointedly drew the attention of the Chair to the phenomenon, and hotly declared that ridicule was not argument. An energetic disclaimer from the one reproved followed, who, however, expressly reserved his right to smile on all appropriate occasions. Then, with the ground cleared, the two set to in earnest, the lecturer, perfectly conscious that he had tripped, discreetly remaining in the background. In vain Mr. Jobling tried to entice the office boy into 10 per cent. admissions, but all he could extract was a statement that the proportions given indicated one grain of the solid in every 10 minims of solution. Watching his opportunity the lecturer sprinted for the next topic, and was at once accused by the valiant extra-turn of "crawling out of the pit he had dug." "Easily done, as it is a very shallow hole," neatly replied Mr. Thomas, and thenceforth was left in peace.

A number of instructive tests and experiments followed in relation to photographic procedure. Speaking about indicators, he had a strong preference for methyl orange and phenolphthalein over litmus. By mixing a trace of the phenolphthalein with sulphite solution he showed that any alkalinity is detected by the solution turning red, which can be neutralised by the cautious addition of a 10 per cent. solution of hydrochloric acid (dangerous ground again) till the solution turns white. Amidol in alkaline sulphite solution is apt to cause fog; and this simple procedure, he said, will be found of service. Among many other practical tips was mentioned the efficacy of mouth operated pipettes, with cyanide solutions for all weary of life. Also, that solutions of metabisulphite should never be boiled, and the crystals kept from contact with air so far as possible.

In answer to a question he said that bringing neutralised sulphite (Piper's formula) just to the boil as advised, possibly caused a double salt to form, which might add to the keeping qualities of the solution. A most hearty vote of thanks was accorded Mr. Thomas for an evening altogether excellent.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Henry Charles Mahoney and William Dimsdale Stocker, carrying on business as photograph trade workers, at 35s, Duke Street, Brighton, under the style of Mahoney & Co. All debts due to and owing by the late firm will be received and paid by William Dimsdale Stocker.

Notice is given that the creditors of the Oxford Optical Company, Limited (which is being voluntarily wound up), are required, on or before February 14, 1922, to send particulars of their debts or claims to Henry Johnstone Veitch, 56, Moorgate Street, E.C., the liquidator of the company.

NEW COMPANIES

I. J. SMITH, LTD.—This private company was registered on December 31, with a capital of £400 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in photographic appliances, etc. The first directors are: I. J. Smith, 162, Conybere Street, Birmingham, drug merchant; F. C. Harrison, 16, St. John's Road, Harborne, Birmingham, chemist. Qualification: One share. Registered office: 162, Conybere Street, Birmingham.

C. S. YEATES, LTD.—This private company was registered on December 29, with a capital of £6,000 in £1 shares. Objects: To carry on the business of engravers, photographers, photographic printers, manufacturers of films, magic lanterns, and all machinery and appliances required or used by photographers or cinematograph proprietors, etc. The subscribers (each with one share) are: A. J. Hull, 30, Castleton Road, Goodmayes, clerk; M. G. May, 102, Powerscroft Road, Clapton, E., clerk. The subscribers are to appoint the first directors. Remuneration as fixed by the company. Registered office: 14, Hatton Wall, E.C.

BAKER'S ILLUSTRATED GUIDES, LTD.—This private company was registered on January 2, with a capital of £2,000 in £1 shares. Objects: To carry on the business of advertising contractors and agents, printers, engravers, photographers, billposters and agents, etc., and to adopt an agreement with H. A. Fry. The first directors are: R. A. Tuckey, 130, The Avenue, Tottenham; P. E. Lavell, 59, South Side, Clapham Common, S.W.; C. Gibson, 28, Alcester Crescent, Upper Clapton; C. J. Marshall, Chiltern, Gloucester Road East, New Barnet; J. J. Gillan, 189, Mount Pleasant Road, Tottenham. Qualification: £250. Remuneration as fixed by the company.

T. DUNNILL SYKES, LTD.—This private company was registered on January 4 with a capital of £7,500 in £1 shares (5,000 5 per cent. cumulative preference). Objects: To take over the business of photographers, colour printers and lithographers carried on by T. Dunnill Sykes and E. D. Galpin at Bank Chambers, 329, High Holborn, and elsewhere, as "T. Dunnill Sykes." The first directors are: T. D. Sykes, 3, Compton Avenue, Brighton, Sussex; E. D. Galpin, Connaught Hotel, Leinster Square, W. (both permanent, subject to holding 400 shares each). Qualification of other directors, £50. Remuneration, as fixed by the company. Registered office: Bank Chambers, 329, High Holborn, W.C.1.

JAMES ENGLISH AND CO., LTD.—This private company was registered on January 3, with a capital of £20,000 in £1 shares. Objects: To take over the business of manufacturers of card and cardboard, and paper merchants carried on at Peerless Works, Radsworth Street, Baldwin Street, City Road, E.C., and elsewhere, as "James English and Co.," and to carry on the same and the business of manufacturers of mounting and Bristol boards, photographic mounts, etc. The subscribers (each with one share) are: Mrs. K. M. English, 122a, St. James' Court, S.W.; L. E. Giffen, 81 and 87, Gresham Street, E.C.2, solicitor. The first directors are not named. Registered office: Peerless Works, Radsworth Street, Baldwin Street, E.C.2.

STEREOSCOPIC EXAMINATION OF BANK-NOTES.—A writer in one of the evening papers advises the use of the stereoscope for detecting bogus bank-notes. A known good note and a suspected one are placed side by side in the rack on top of the usual binocular view, carefully adjusted and focussed. The examined parts seen under the lens should, of course, appear as one picture. If the two notes do not coalesce, then there is something wrong.

News and Notes.

MESSRS. J. H. DALLMEYER, LTD., of Carlton House, 11d, Regent Street, Piccadilly Circus, S.W.1, advise us that a camera bearing the following description was stolen from their stand at the exhibition held by the Physical Society and Optical Society at the College of Science and Technology, Exhibition Road, South Kensington, on January 4 and 5, 1922:—Quarter-plate double extension folding pocket camera, fitted with 2 Series V Dallmeyer Perfac lens, No 95130, fitted in No. 0 Universal shutter. They will be pleased to hear from anybody who may have such a camera offered to them.

THE ROYAL ACADEMY WINTER EXHIBITION.—This is a show of works by recently deceased masters of the British School. It is a sweet, refreshing breath from the days of our youth when men used to do their best, and it comes across present-day arid sophistication and affectation with a promise for the future. All who are tired of the futilities of modern painting which abjures nature, and craftsmanship and accomplishment and feeling, should go to this exhibition and see again how wrong are the critics who maintain that a picture which has a subject is necessarily negligible. The gorgeous colour and truth of the Stotts are alone worth a visit.

THE LATE DAVID BACHRACH.—We regret to see announced in the American papers the death on December 10, at the age of 76, of Mr. David Bachrach, a pioneer of portrait photography in the United States, and the head of the well-known Bachrach studios in New York, Baltimore, and other towns. Of German birth, Mr. Bachrach began photography when a mere youth at about the beginning of the Civil War, and took a portrait of Abraham Lincoln in 1863. For a time he was a photographer at Fort Gilmour, and afterwards was in charge of surgical photography at a hospital. He began business for himself at Baltimore in 1869, and throughout his career was constantly experimenting in the improvement of photographic processes. He was a co-worker with Louis Edward Levy in the production of the half-tone screen, and himself invented a method of making prints on painters' canvas and of preparing a paper in which the gold was incorporated in the sensitive coating. Apparently he was the first man to make such self-toning paper, although by a different method from that afterwards adopted for emulsion self-toning papers. He was a prolific contributor to the American photographic Press years ago, and was instrumental in exposing many of the fraudulent secret processes largely offered in those days. Until the end of his life he took an active interest in the general well-being of photographers. One of his last successful campaigns was that undertaken two years ago for the removal of photographs from the proposed list of articles which should bear a luxury tax.

A PROFESSIONAL PHOTOGRAPHER'S EXPERIENCES.—An "Evening News" representative has been having a talk with Mr Walter Stoneman (J. Russell & Sons, of Baker Street, W.), who has now an exhibition of seventy-four portraits, "Men of Mark," at the Royal Photographic Society. It seems (says the reporter) that most great men creep to the photographer's studio with reluctance and apprehension. They are more nervous in the presence of the camera than are women, and they arrive anticipating trouble. Mr. Walter Stoneman thinks that many would avoid the camera altogether were it not that they are persuaded *or ordered* by their wives and daughters to give a sitting.

"The most common obstacle I have to surmount is that the male sitter will think of one as an operator," says Mr. Stoneman. "They class my studio with the dentist's surgery and the surgeon's theatre. Though the head-rest is a 'back number,' they behave as if it were still there. One would prefer to have a talk with them beforehand, and indeed I try to do that, but the big men are invariably too busy to give me more than ten minutes—and in that time I must get a characteristic likeness and a pleasing portrait.

"It is fatal to handle your sitters: you must get your pose by suggestion and capture a fleeting expression. Bishops and actors are easy, being accustomed to adopting reposeful attitudes. I have found men of science simple too: strength has come to their faces through study, and the character remains on the surface.

"The difficult man is the modern hustler—a nervy man who seems to live on wires. His appeal to our senses is largely through his vigour; the essence of his impressiveness is in his movements. It is astonishing to find that from the photographer's point of view the hustler is invariably a dummy in repose. The light of action gone from the face, there seems to be nothing left. A very mobile face presents difficulties, too. A certain admiral has a very mobile mouth. In repose something happens to that mouth which seems to definitely rob the camera of a true likeness. I exposed seventeen plates before I caught a good portrait.

"Their nervousness apart, I consider men easier to photograph than women," he said. "A man indicates his character in his face more than a woman does. A woman carries something I can't define—but it's elusive."

Correspondence.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen, I have received a form of application for membership of *The Professional Photographers' Association of Great Britain and Ireland, Ltd.*, which is headed by a request that I shall fill it in and return it to the Secretary.

I find that if I sign it I bind myself to the statement that I am eligible for membership under Clause 5 of the articles of association, and also that I agree to be bound by the memorandum and articles of association of the said Association. I am, of course, aware that the new Association is a reorganisation of the old P.P.A., and I am also aware that the incorporation necessarily involved an alteration of the old rules, but, as the management has not seen fit to communicate to the members what the new conditions and obligations are, I can only view the request for my signature as one equivalent to asking me to hand them a blank signed cheque. I have always understood that the business of the Association was conducted by a Council of men well acquainted with business procedure, but this invitation to the old members to take a leap in the dark is certainly not indicative of any knowledge of correct business methods. I do not suggest that there is any want of straightforwardness, but those responsible for the issue of this little bond we are expected to sign without inquiry would find it difficult to defend themselves from a charge of lack of the sense of humour; for I read in the little Handbook, issued periodically to members, containing much sound information on the conduct of business, this advice which meets the case exactly:—

> "Members should be extremely careful not to sign any paper before reading it word by word, and making certain that they understand precisely what it commits them to. A signed document cannot be set aside at law, and the literal statements made therein cannot be disputed on any grounds whatever."

Since the war there seems to be quite a different spirit in the management of the Association. Formerly, there may have been some want of enterprise, but the policy was a safe one, and whatever was attempted was carried out. Now the reports of the proceedings of the Council seem to show a tendency to make extensive changes to decide upon great enterprises without due consideration as to whether they can be successfully carried out, and to claim great efficiency in the ordinary routine work, a claim that in my experience is entirely unjustified. We used to have a quarterly "Circular." That publication ceased long ago, and we were promised in its place a monthly publication, which was to be of real importance, with advertisements and all the rest of it. It is still in the land of unfulfilled promises. Now, I see the Congress is to be the subject of an experiment. The advantage of holding it in connection with the Photographic Fair at the Horticultural Hall, which I understand we had our accommodation free, and at a convenient time of the year for most photographers, is to be abrogated, and the next Congress is to be held at an inconvenient

time of the year for many, at a place which will have to be rented at considerable cost, and which will certainly be without the attractions that the Fair offered in the opportunity of viewing the apparatus and materials there to be seen. I cannot conceive that the change can make the Congress more successful than its predecessors, but I can quite conceive the possibility of a very desperate failure.

It would be interesting to know why the well-honoured old title of the Association was changed to its new, lengthy and, indeed, clumsy form.

AN OLD MEMBER P.P.A.

THE P.P.A. CONGRESS.

To the Editors.

Gentlemen,—I read with interest the letter from Mr. H. L. Kettle in your last issue.

The Council of the P.P.A. seem to have acted in rather an autocratic manner in the alteration of the date and meeting place of the annual congress. There was no suggestion of considering the convenience or interest of the members, for as far as one knows no dissatisfaction had been expressed with previous arrangements. The date was without doubt the most suitable for the majority of provincial members.

The rank and file of the P.P.A. members have actually very little to say as to the conduct or policy of the Association. There is a tendency on the part of officials to keep ordinary members in their places. At congress meetings, lectures, etc., Council members only are asked to take the chair, to move or second votes of thanks. In fact, there is a trifle too much of the spirit evinced on the occasion of the visit to the Guildhall last year, when ordinary members were told that "Front seats were reserved for members of the Council only," and later were asked to remain inside the Guildhall until the Council had been photographed, and then were allowed to come out for the general group.

Generally speaking, however, the arrangements were good and well carried out. I am personally quite disappointed that the alteration has been made, as I shall in all probability be deprived of what has been a keenly anticipated and pleasant holiday.—Yours faithfully,

GILBERT N. FUTCHER.

Palmerston Road, Southsea.
January 9.

To the Editors.

Gentlemen,—Your Scarborough correspondent is certainly wholehearted in his disparagement of the Council of the P.P.A. I was very sorry to read such sweeping depreciation by a fellow member. Surely he is suffering, as I am, from the reaction of the strain of Christmas rush, but it affects its victims differently. Whilst disclaiming to be a grumbler, one cannot find any other sentiment in his letter. He has not a word of praise for the Association, and he may discover that the bulk of members do not think as he.

Being a "seasider," a congress in September will be far less convenient to me than in April as heretofore, but I shall make my arrangements accordingly. It would be a sheer impossibility for any organisation with a widespread membership to fix its dates so that they were absolutely convenient to everyone. We all have to make some sacrifice to be present.

I have no more information than your correspondent of the reasons the Council have for fixing on the month of September for this year's Congress, and think it a courageous thing to do, but I have sufficient faith in the wisdom and busines acumen of the men who act for us as a Council to know that they would not rashly jeopardise its success without careful consideration and without an object which they regard as greatly to the advantage of the Association and the members of the Congress.

The alteration of date may or may not prove a success, but, at any rate, the Council is entitled to our confidence. If it is not a success, your correspondent will have the satisfaction that it was no fault of his.

The London members seem particularly in his disfavour by his implication that the date is altered for their convenience. Has he overlooked the fact that the Council consists of an equal number of country members? He refers to the increased cost of membership. I recall that this is not attributable to the Council.

It was the members of the Association at the annual general meeting who doubled the subscription, as it was imperative, and the increase met with general approval.

Yet he complains that he does not get a "Circular" more frequently, and that members are not getting enough for their money. I cannot agree with him. If membership of the P.P.A. is not worth a subscription of 10s. a year, it is not worth anything.

Surely the tendency of thought nowadays should be less of "what do I get out of it." It is a true adage that "we get what we give." The Association reports show frequently that some member or other is being helped very considerably, and in such a manner as he could not help himself. If your correspondent has not had reason to receive the help and advice which are always available, it may even yet come his way.

We cannot afford splendid isolation in these days, and I should like to pay my tribute to the self-sacrificing work of our Council, and the unstinting comradeship and goodwill, which are invariably the predominant features of the Association in congress. Those who attend know.

Meanwhile I hope your correspondent will take a more hopeful view of the future of the P.P.A. and its probable longevity, and will continue his membership. Pardon such a lengthy trespass on your space.—Yours very faithfully,

OSCAR OWERS.

51, Fawcett Road, Southsea.
January 9.

To the Editors.

Gentlemen,—I was very glad to see Mr. H. L. Kettle's letter in your publication of January 6. It entirely expresses my views, and no doubt quite a considerable number of country members of the P.P.A. I have been a regular attendant at the Congress for a number of years, and although a little business has been lost through being away from the studio a week each April, I am more than certain I have gained in many other ways. I contend that April and May are the best months to hold the Congress; it is just the time of the year when we have our "spring cleaning,' are renewing our stock of mounts, etc., and desire to meet photographers and talk things over. The lectures and debates are very valuable in many ways, and I personally have gained valuable hints and ideas which have been put to advantage during the season. September for the Congress is entirely out of the question for the seaside photographer, as that is one of *the* months.

If the Congress is held in September I shall be unable to attend, but shall come to the Fair as usual. Was not last year's attendance at the Congress a record? The number of members who attend each April/May ought to convince the Council as to the best time of the year for a Congress.—Yours truly,

13 YEARS A MEMBER.

COLOUR PHOTOGRAPHS OF STAGE PLAYS.

To the Editors.

Gentlemen,—As I am given to understand that a member of the Liverpool Photographic Society produced some years ago natural-colour photographs of stage plays, taken during the ordinary performance, and by the usual stage lighting, I should feel obliged if you would insert this letter in the "British Journal of Photography," in the hope that it will catch the eye of someone able to give the gentleman's name.

Any information concerning the above, or photographs of like nature, would be extremely valuable, owing to the large amount of interest now being shown by many colour workers in this branch of photography.

It is extremely difficult to understand how such results could have been obtained in pre-war days, as developments in high-speed colour photography, such as improved filters and ultra rapid panchromatic plates, are of quite recent introduction.

Before I attempted my own experiments I discussed the matter with a gentleman very well known in the world of photography, who for the last fifteen years has been in close touch with the majority of colour workers, and he informed me that he had never seen or heard of any results being successful. Although he had

experimented on the same class of subjects his results had been disappointing, and he suggested I had better not waste time or money trying to achieve the impossible.—Yours faithfully,

THOS. J. OFFER.

244, High Holborn, W.C.1. January 9

DYEING SENSITIVE FILMS FOR RELIEF PRINTS.

To the Editors.

Gentlemen,—I was perfectly cognisant of U.S. Pat. 9 0,962, 1911, when I wrote the passage to which Mr. F. E. Ives takes exception. Adopting his gambit, "in the interest of correct historical record," permit me to point out the following data :—

Ducos du Hauron, "La Triplice Photographique et l'Imprimerie," Paris, 1897, pp. 261-263; after pointing out the exceptional circumstances in working the carbon process, particularly the blue tissue, in Algers, du Hauron says: "L'idée me vint, il y a un dizaine d'années, de combattre cette cause d'insuccès en introduisant, soit soit dans le mixtion collide bichromatée, soit dans le bain sensibilisateur de bichromate, une substance colorante fortement anti-photogénique qui, au lieu d'être par elle-même insoluble dans l'eau comme la couleur minérale du monochrome bleu, s'éliminerait complètement par les bains de dépouillement et de lavage. Je fis choix d'une couleur d'aniline soluble dans l'eau additionée d'un peu d'alcool; c'était la *fuchsine jaune*, à l'état de pureté, désignée également sous le noms de *coralline jaune* et de jaune d'or (d'aniline). Cette substance, et il en existe d'analogues, s'acquitta à merveille du rôle que je lui confai; elle favorisa à souhait, sous un autre rapport, la venue de mes photocopies au charbon, et particulièrement du monochrome-bleu, en ce qu'elle permettait d'abaiser, même bien au-dessous des proportions indiquées par les auteur, la dose du bichromate; tant et si bien que nonobstant la forte chaleur de la saison ou j'expérimentais, la lumière ne fouillait jamais trop profondément de celle-ci que ce qui devait être insolubilise. En presence de cette réussite, il me parut de bonne guerre, étant donnée la grande vogue dont jouissaient encore, à cette époque, les phototirages aux mixtions bichromatées, de donner une date certaine à cette trouvaille par le prise d'un brevet. Je le pris le 17 Decembre, 1885 (sous le nombre No. 173,012), et le lassait du reste tomber, peu de temps après, dans le domaine public."

Anglicised, this reads: "The idea occurred to me, about a dozen years ago, to combat this source of ill-success, by introducing, either in the dichromated colloid mixture, or in the dichromate sensitising bath, a substance of a strong non-actinic colour, which, instead of being itself insoluble in water like the mineral colour of the blue monochrome, would be completely eliminated by the development and washing baths. I chose an aniline colour soluble in water with the addition of a little alcohol; it was fuchsine yellow, in a pure state, also known under the name of yellow corallin or aniline gold yellow. This substance, and analagous ones exist, marvellously discharged the rôle which I entrusted it. It assisted as desired, in another respect, the advent of my prints in carbon, in that it permitted the reduction of the strength of the dichromate, even below the proportions indicated by the makers; to such a degree and so well that notwithstanding the great heat of the season when I experimented, the light never penetrated too deeply into the film and did not insolubilise that which should be soluble. In the face of this success, it appeared to me to be fair but, given the great vogue which printing with dichromated mixture would still play at this time, to give a definite date to this work by taking out a patent. I took it out December 17, 1885 (under No. 173,012), and it was allowed, moreover, to fall a short time after into public domain."

The title of the said patent is "Nouveau modes de papiers mixtionnés ou produits analogues pour la Photographie di e au charbon, caractérisé par l'incorporation provisoire d'une teinture."

A. & L. Lumière, "La Photographie des Couleurs," Lyons, 1901; Bul. Soc. Franç. Phot., 1901, Vol. 48, 204, 303, 411: Photo-Rev., 1901, 121, 170, 182; Brit. J. Phot., 1902, Vol. 49, 52; J. S. C. I., 1902, 275; Phot. Woch., 1901, 147; Eder's Jahrbuch, 1900, Vol. 14, 662; 1901, Vol. 15. 272, 545; 1902, Vol. 16, 533; Eder's Handbuch, 1903, Vol. 3, 702; Vidal, "Traité pratique de Photochromie." Paris, 1903, 195.

After describing the reasons for their choice of the carbon process and the inconveniences of the same, MM Lumière state: "La couche sensible se laisse pénétrer trop profondément par la lumière, ce qui fournit des monochromes dont le relief, trop considérable, est un obstacle à la convenable superposition ultérieure des trois images élémentaires. Nous avons remédié a ce défaut en introduisant dans les préparations gelatinées une matière colorant s inactinique empêchant la pénétration des rayons lumineux dans l'épaisseur de la couche sensible. Cette matière colorante doit en outre présenter les qualités, su' antes: elle doit pouvoir être facilement éliminée par lavage: après développement elle ne doit donc se fixer ni sur la gélatine ordinaire, ni sur la gélatine chromée; elle doit, en outre, être sans action sur les bichromatea alcalins. Après avoir essayé dans ce but plusieurs centaines de couleurs, nous n'avons trouvê pour remplir ces conditions que le rouge-cochenille resultant de l'action de l'acide naphthionique sur l'acide β-naphthol disulfonique."

Anglicised, this reads: "The sensitive film is very deeply penetrated by light, which gives mono bromes with very high relief, which is an obstacle to the subsequent convenient superposition of the three elementary images. We have remedied this fault by introducing into the gelatine preparations a non-actinic colouring matter preventing the penetration of the light-rays into the thickness of the sensitive film. This colouring matter ought, however, to present the following qualities: it ought to be easily eliminated by washing; after development it ought not to be fixed on the ordinary or chromated gelatine; it ought, moreover, to be without action on the alkaline dichromates. After having tried in this respect several hundred colours, we have found to fulfil these conditions cochineal red made by the action of naphthionic acid on β-naphthol disulfonic acid."

The Lumière N. A. Company, in 1900, introduced commercially such films in the English market, and I had a finger in the manufacture of the same.

O. Pfenninger, Eder's Jahrbuch, 1909, Vol. 23, 45, says: "Ich fand nämlich dass blaues Pigmentpapier immer zu kräftig und zu kontrastreich arbeitet; dem abzuhelfen, gebrauchte ich ein Chrombad folgender Zusammentse'zung: 5 Teile fünfprozentige Chrom-Pottaschelösung mit Alkali vol. halb neutralisiert und 1 Teil einprozentige Säuregelbloaung. Mit Gelb- und Rotpigment wirkte diese Mischung nicht anders, wie reine, neutrale Chromsalzlösung, hingegen arbeitete das darin sensibilisierte blaue Pigmentpapier flauer, und ich erhielt dadurch ein mit den zwei andern Teilbilder, harmonierendes und besser entsprechendes Resultat. Die Erklarung ist darin zu suchen, dass die Anilinfarbe intensiver färbt und auch die blauaktinischen Strahlen besser zuruckhält, wie das Chromsalz allein."

Anglicised, this reads: "I found that the blue pigment paper always worked too vigorously and hard; to help this, I used a dichromate bath of the following composition: 5 parts of a 5 per cent. solution of potassium dichromate full half-neutralised with alkali and 1 part of a 1 per cent. solution of acid yellow. With the yellow and red pigments this mixture did not act differently to the neutral chromate solution; on the other hand, the blue pigment paper sensitised therem worked flatter, and I obtained a result more harmonious and corresponding better to the other two constitnent pictures. The explanation of this is to be sought in that the aniline colour stained more intensely and held back better the actinic blue rays."

From the above excerpts it is clear :—

1. That Ducos du Hauron anticipated U.S. Pat. 980,962, 1911, by 25 years.

2. That MM. Lumière anticipated the said patent by 10 years.

3. That Pfenninger anticipated it by one year

And Mr. Ives says that this method was "afterwards adopted by the parties named without credit to me."

WHITE'S CAMERA.

Mr. Ives claims to have invented this type of camera, and quotes U.S. Pat. 351,940, 1894. There is an error here as the number should be 351,040. This patent is the same as Eng. Pat. 2,305, 1895, an abstract of which was given in the Patents Chronology, Col. Phot. Supp., 1907, Vol. 1, 24, with figures. From this it will be seen that the Ives patent is for two or three reflectors at an angle of 45 or 22½ degrees to the base, and *all parallel to one another*. White's camera, E. P. 8,663, 1896, and 18,875, 1898, abstracted in the same volume, pp. 32, 40, is for two reflectors only, but *at right angles to one another*. Surely one cannot assume that two or three parallel lines are the same as two at right angles to one another.

Yours faithfully,

E. J. WALL.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

M. E.—The rubber gloves to which you refer are sold by Messrs. Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2.

R. G.—There are no patent rights in the process of mounting a photograph and cutting out the outline of the subject. Trade names for such portraits may have been registered, but, speaking from memory, we do not think they have.

W. H.—The Ives "Tripak" camera has not been on the market in this country, and we are doubtful if it is on the market in America. All you can do is to write for particulars to Mr. F. E. Ives, 1,327, Spruce Street, Philadelphia, Pa., U.S.A.

M. R. B.—Difficult to say from the scanty particulars. We suggest exposure of cards to white light while in the fixing bath or shortly afterwards. Some papers are sensitive in this respect. We shall be glad to advise further on receipt of further particulars of paper, developer, fixer, and manipulation.

X.—We certainly think that the features you describe are a great improvement on the present article and, providing there are not corresponding drawbacks, would largely displace the present pattern. You should protect the invention by patenting or by registering a design. Particulars for either from 25, Southampton Buildings, London, W.C.

H. P.—We have not any knowledge of special investigations, but general experience is that a developing or fixing tank of copper or brass has a very long life in continuous use if the tank be rinsed and wiped dry after use; that is to say not left exposed to air and also to the action of adhering developing or fixing solution. We do not think there is anything in the statement that the effect of brass on developer is to cause chemical fog on the plates. Both brass and metal last longer if nickelled, and if the precautions mentioned above are taken the metal coating remains in its original condition for a very long time.

P. S. P.—Fellowship of the Royal Photographic Society is granted to persons who are already members of the Society and have been so for, we think, at least one year, and in the opinion of the council have contributed in one or other of a number of ways to the advancement of photography. The Society does not set any standard of qualification which must be reached in order that the Fellowship shall be granted. The most that it does in this direction is to issue a statement of the general grounds on which members are admitted to the Fellowship. A copy of this publication can be had on application to the Secretary, 35, Russell Square, W.C.1.

F. B.—Reduction of such extremely fine lines to one-quarter width is a process which taxes the resolving power of a dry plate to the utmost, and we think you will have a great deal of difficulty in retaining the lines, whatever method of working you adopt. There might be some advantage in using a fairly deep yellow filter, but we very much doubt it. We think the most hopeful direction in which to work is to use one of the "fine grain" plates, giving just sufficient exposure to develop up an image without forcing, and then to intensify strongly with the Monckhoven intensifier of silver cyanide. The real fact is that this is a job which requires a wet collodion plate for satisfactory work, and is not the easiest job even with that.

S. J. B.—About sixteen full size burners, either inverted or upright, are needed for taking single figures of a group of two or three at most. For ten figures you would require about three times this number. We should advise you to write to Griffins, of Kingsway, for particulars of the Howellite burners, which are decidedly the best for photographic purposes. The principal objection to gas is the great heat which is generated; much to the sitter's discomfort. For the large groups we should recommend flashlight, using the single figure lamp for focussing. We imagine from your letter that your lenses are not of a very rapid type. It is not much good, if you want to use gas, to work with an aperture smaller than *f*/5.6.

A. F.—We think the change in colour, due to exposure to light or air, or both, is due to one or other of two things. It may be caused by a natural change in the raw base on which the emulsion is coated, although we think it very unlikely that such a change could take place to such a marked extent during the weak light at the present time of year. The other possible cause is that the sulphide solution did not act long enough on the bleached prints to convert every trace of the bleach image into sulphide of silver. If there were a certain small amount of bleach image left in the whites, these would almost certainly change in colour on exposure to light. Therefore, we think the most likely quarter to look for the cause of the trouble is in this latter direction.

E. P. F.—(1) There is now no procedure as a preliminary to creating copyright. According to the 1911 Act copyright is automatically created by the creation of the work. (2) It is not necessary that the word "copyright" should be marked on copies in order to safeguard the copyright in them. (3) Impossible to say if the photographs are of interest to the Press, or to express an opinion from the facts you state as to whom the copyright belongs. It may be the property of either the photographer or the sitter. Fees range from 10s. 6d. upwards. (4) Presuming the copyright is your own, you can grant licences for reproduction in various publications and in various classes of publication, and separately for use as postcards or calendars, in which case it is important that you should not grant any licence which can possibly be interpreted as a complete assignment of the copyright.

M. L.—(1) Amidol is not a practicable method of desensitising plates. We mention it in the "Almanac," because experiments with it were the start of the use of safranine dyes by Dr. Lüppo-Cramer. (2) We have no practical experience of the desensitising properties of triamido-tolnol. (3) You can probably buy from British Drug Houses, Ltd., 16-30, Graham Street, City Road, London, N.1. (4) Potassium permanganate is much too strong an oxidising agent and greatly affects the latent image. It is useless for desensitising. (5) The Kallitype process supplies excellent prints of matt surface and of a range of tones from cold black to purple. From suitable negatives of somewhat good vigour the results are almost as good as those on gaslight or bromide papers as regards gradation. (6) Bichromate solution applied by brush or floating to a paper coated with gum and pigment penetrates not only the gum coating, but the paper support. On exposure to light the more or less insoluble image is formed chiefly on the surface, but not exclusively. We daresay it would be possible to apply the sensitiser to the back of the paper and so obtain rather more insolubilising action in the lower layer of the film, but we do not think the difference would amount to anything appreciable.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3220. Vol. LXIX. FRIDAY, JANUARY 20, 1922. Price Fourpence.

Contents.

SUMMARY.

A competition, in which prizes amounting to £3,000 will be awarded, is being organised for photographs taken with British cameras from negatives on British plates, and printed on British printing papers. On page 29 we specially direct attention to this piece of enterprise, particulars of which will be found on page 42.

A photographic method of producing a newspaper has been inaugurated by the "Blackpool Times," which now is printed by an offset machine, working from metal plates on to which letterpress and illustrations have been photographically printed. The illustrations are thus produced without the aid of half-tone blocks, and, moreover, have a technical quality greatly superior to that obtainable by impressions from half-tones on newsprint. (P. 42.)

The principles and practice of stereoscopic photography of small objects are the subject of a paper by the Rev. H. C. Browne, the first portion of which deals with the general conditions of making and viewing and the design of stereoscope and camera. (P. 34.)

In a contributed article "Thermit" deals with the practical qualities of the retoucher's equipment, e.g., pencils, brushes, knives and mediums, and gives some hints on the proper use of these requisites. (P. 31.)

The Professional Photographers' Association has officially issued a statement of its policy regarding the holding of this year's Congress in the autumn. (P. 37.)

In a leading article we endeavour to bring together a few of the chief considerations which require to be borne in mind in obtaining poses of men and women which are pleasing to the sitters. (P. 30.)

A striking collection of portraits of notabilities by Mr. Walter Stoneman is on view at the house of the Royal Photographic Society, 35, Russell Square, daily, from 11 a.m. till 5 p.m., till January 27. (P. 37.)

The use of an ordinary camera in the making of panoramic prints in sections is the subject of an article by Mr. C. F. Stiles in "American Photography." (P. 33.)

There is evidence that good specimens of the Daguerreotype process are commanding much higher prices among collectors (P. 29.)

A construction of dry-mounting press, designed to obviate injury of the platen through excessive pressure, is the subject of a recent patent specification. (P. 38.)

At the Royal Photographic Society on Tuesday evening last, Mr. H. V. Lawley described the extremely efficient plant designed, made and used by himself, for the continuous development, fixing, washing and drying of cinematograph film. (P. 41.)

Provided a good print is available, a reproduced negative, which is to be printed on a matt or rough paper, may frequently be made with advantage by contact. (P. 30.)

EX CATHEDRA.

Daguerreotypes. We hear that of late good specimens of the Daguerreotype process have been obtaining substantial prices. Although for many years past really good examples of the process have been by no means common, they have commanded only miserable prices. At auction sales we have frequently seen a collection of a dozen or so, including some which were excellent specimens, knocked down at a price which represented a few pence each. But it now appears that collectors of specimens of early processes of fine arts and crafts are taking an interest in Daguerreotypes, with the consequent result of an increase in the price which can be obtained for them. From our own experience in disposing of a small collection left by a deceased friend we have confirmation of this tendency. After having declined offers which did not rise above sixpence or a shilling, we have gradually disposed of the greater number in no case at less than half a guinea each. A really good coloured specimen by one of the early Daguerreotypists of repute, such as Claudet, is worth a good deal more; it may be worth what was charged for it at the time, namely, five or six guineas. Specimens can still be picked up every now and then on the stalls of dealers in odd goods at the Friday Caledonian market. A friend recently showed us a very fine specimen by Claudet which he bought there a little while ago for a penny. In bringing these facts before the many owners of Daguerreotypes who are doubtless among our readers, we must not omit to point out that the glass collodion positive, which by the inexpert is frequently mistaken for a Daguerreotype, has an insignificant value. It is, however, perfectly easy to distinguish with certainty between the two: the back of a Daguerreotype is of copper metal; that of a collodion positive, of glass.

* * *

An All-British Competition. Amateur photographers and the retail dealers who supply them will give an especially warm welcome to the competition in which £3,000 will be awarded in prizes during the present year. For the competition is organised by a group of British firms, and is designed to promote those branches of manufacture in particular with which British firms have been long and honourably connected. At the present time, owing to the economically disturbed condition of almost every country in the world, the difficulties which manufacturers in this country have to overcome were perhaps never so severe, and the firms who have joined with one another in the organisation of this competition are entitled to receive the respect and support of the photographic public for their constructive and enterprising piece of policy. Incidentally, the amateur photographer is given an opportunity of winning one or other of the numerous cash prizes, ranging from £100 to £1, offered in the competition, or rather competitions; for there are two of them, one closing on June 30 and the

second on November 30. These competitions are for photographs taken with one or other of nine different models of British camera on one or other of eight makes of British plates, and printed on one or other of the same number of British papers. Full particulars and entry forms of the competition will be obtainable within the next week or two from photographic dealers throughout Great Britain. It is requested by the promoters that application should be made to the dealers, and that only those removed from the opportunity of obtaining the literature through this channel should apply to the special headquarters which have been established for the competition at 4, Oxford Street, London, W.1.

* * *

Letters to the Editor. Among the features of a trade or technical newspaper those to which many readers invariably first turn are the "Letters to the Editor" and "Answers to Correspondents." We say this, not simply with the idea of paying an uninvited compliment to our readers, but as the result of general observation in respect to readers of the "B.J." and many other papers. Perhaps the "Letters to the Editor" particularly attract first attention, and, therefore, we can thoroughly endorse the remarks recently made by a London evening newspaper on this subject:—"Professor John Adams is right when he says that the readers of a newspaper are like a ghostly committee for carrying new developments. They never meet; they see one another, mostly, only across railway compartments and omnibus gangways and restaurant tables. But though they are a committee without meetings, they do, as the professor says, get things done, and one of their most effective instruments is the Letter to the Editor. If readers knew how very seriously the columns of their Letters to the Editor are examined . . . . . they would be astonished. No reader should believe that a man or woman who writes a letter to the Editor is regarded with hostility in a newspaper office. Every letter is welcomed that has something to say, says it, and then stops.

* * *

Negatives from Prints. When making a negative from a print it is usual to do so either by copying, or if the picture is required upon a larger scale, by means of a contact transparency upon a lantern or other slow plate. A very simple way which dispenses with the need for the intermediate transparency when reproducing negatives, and one that might be more widely employed than it is, is by printing upon a slow or process plate from a good print. The only objection to this method is that the grain of the paper shows slightly in the new negative, but when this can be printed, or enlarged upon a rough surface paper, this is a matter of little moment, provided the grain is not unduly in evidence. A glossy P.O.P. print of good depth, or a glossy bromide print, is about the best for this purpose, and one upon a thin, smooth paper base is, of course, preferable. The exposure is made in an ordinary printing frame with the two films in contact; six or eight seconds at twelve inches from an ordinary bat's-wing burner being about right for most process plates. There is no need to make the paper print translucent; it is a messy job and is of little benefit in reducing the effect of the grain of the paper. Transferotype bromide paper may be of value here. Some time ago we were shown a number of prints from reproduced negatives; instead of the prints in the first instance being made upon ordinary bromide paper, Transferotype paper had been employed, the image transferred to glass, and the new negatives then made by contact. The above method has the advantage of economy in the use of materials over the usual methods of reproducing negatives.

PLACING THE FIGURE.

An apparently simple task, the correct placing of the figure upon the plate, is a rather common stumbling-block for many portrait photographers. The modern practice of trimming the print to suit the subject allows of correction to a certain extent, but very often it is necessary to cut down to a size much smaller than that which was ordered, so that the photographer has either to resort to enlargement or to send out a distinctly inartistic production. While there are no definite rules as to what should be included in a photograph or what position the figure should occupy, any error in this direction is readily perceptible to anyone with a modicum of taste. The portrait may be excellent as far as technique and expression is concerned, but it will never be really satisfactory if this one point is overlooked.

The most common error, and one which many otherwise skilful operators fall into, is that of placing the figure too low upon the plate. The effect is that of dwarfing the sitter or, at least, giving the impression that he is slipping out of the picture. This is, of course, the result of pure carelessness, and is often due to the practice of using lines drawn upon the ground glass to denote the various sizes, instead of having a mask which just includes the area of the trimmed print for each size. The ordinary masks, as used in a repeating-back camera, answer the purpose to a certain extent, but they are necessarily rather larger than the trimmed print; it is therefore better to use a mask of the correct size fixed in contact with the ground glass, the edge of which, being clearly defined, shows the limit of the picture. This device is, however, merely a mechanical aid, and does not make up for lack of judgment. The position of the figure must be chosen to suit the subject. For example, a heavily-built sitter placed high upon the plate tends to appear colossal, while a spare one placed at what may be considered a normal height is apt to look rather insignificant. It is an axiom in portrait work that the physical peculiarities of the sitter should not be emphasised, and that as far as possible each sitter should approach an average size. This may not be high art, but it is what is not unreasonably expected. Thus, in the case of a rather short, stout woman it is not advisable to make a full length portrait, but to make a three-quarter length, ending just above the hem of the skirt. This leaves the total height in uncertainty, and gives the impression of a more or less graceful figure. The subterfuge cannot very well be adopted in the case of a male sitter, so that the difficulty has to be circumvented by taking him sitting.

Bust portraits often have an awkward appearance, which is due to their termination at the wrong point. It may be safely assumed that in neither sex should the picture end at the waist, or in some cases where the waist should be. Nothing is more offensive than truncated arms; either a three-quarter length, showing the hands, or a large head are the only acceptable alternatives. A large head should always be placed so that there is a little more room in the direction to which the face is turned than there is behind. It is, however, affectation to leave half the paper in the front of the face blank, as some self-styled artists have done. With regard to head room, it is not usual to allow more than one-third of the height of the head between the top of the hair and the edge of the print, while many of our best artists allow much less.

With sitting figures the dress must be considered when deciding upon the amount to be included, but as a general rule the cut-off should not be at the knees but well below them.

Full-length and half-length figures must be considered as a whole when it comes to filling the space. If the head is centred it will, as a rule, leave too much behind the figure. It is a great help, not only to placing the figure, but to composition in general, to observe the figure upon the ground glass by means of a small hand mirror, so that the image appears the right way up. By so doing many errors in placing and posing may be avoided. A highly-skilled photographer does not need this aid, but the beginner will find it invaluable. When observing the image direct upon the screen the eyes should not be too near the glass, as faults that would be overlooked at a distance of six or eight inches are readily discerned at twice the distance.

The general appearance of most portraits would be improved were it more usual to subdue the lighting of the lower part of the picture, either by casting a shadow upon the draperies or, as is sometimes done, by using a dark camera-vignetter, which allows the details to be seen faintly. This is done with good effect by some of the most successful portraitists.

Fortunately, we are not now bound rigidly to stock sizes, as in the old cabinet days, and we can often effect a great improvement by cutting the print down slightly, particularly when there is too little space in front of the figure; on modern mounts variations of this nature are not readily noticed. Much may be learned from the work of good portrait painters of the present and past generations, and even if picture galleries are not accessible, reproductions of the works of Reynolds, Gainsborough, Lawrence and, for later work, the illustrated guides to the Royal Academy exhibitions may be procured very cheaply, and for the purpose in hand will answer equally well.

RETOUCHING MATERIALS.

I once knew a retoucher whose complete outfit consisted of a small piece of blacklead pencil, a bottle of home-made medium, a second-rate sable, and a chunk of hard Indian red water colour. The pencil was of no particular quality, and the medium was merely a mixture of rosin and methylated spirit.

To any other skilled craftsman an outfit of this type would be not only useless, but ridiculous, yet it is no uncommon thing to come across retouchers working with tools little better than those I have described. And I must admit that the work done with that particular outfit was excellent. But having admitted that, I am not going to admit that the average retoucher can work under the same conditions without the work suffering, or that my friend's work would not have been even better had he taken an interest in his tool box.

There are many outside this branch of photography who think that a pencil, or a pencil and a brush, are the only things used in retouching, but retouchers of experience know that a very large number of things have their uses. There are so many that we might easily divide them into five classes, viz., pencils, brushes, knives, paints and stains and mediums.

Unless a retoucher is fortunate enough to be restricted to one class of negative on one kind of plate or film, no single kind of pencil will cover everything with full satisfaction. Two or three grades, say 2B, HB, and H, or their equivalents, will nearly always be found to repay the extra trouble in keeping and sharpening. Before the war I do not remember ever seeing anything but loose leads in screw-top holders used for retouching, but when these became scarce, as they did in many places, drawing pencils seemed to become common among retouchers. Of the two, there is little to choose except that the pencils are more easily broken. To prevent this I have found a stiff paper tube very serviceable. It is made by wetting a strip of paper with gum or paste and winding it round the pencil until a tube is formed. The tube is slipped off the pencil and allowed to dry hard before being put into use. For some unknown reason, leads without wood are not commonly stocked by artists' sundrymen, or at least I have always experienced difficulty in obtaining them, and when good pencils can be bought in almost any city street there is not much inducement to ferret about for the uncovered leads. It is possible to strip the pencils and transfer the leads to holders, but unless one is very skilful this may prove a very expensive and irritable process. I have tried Venus, Velvet, Royal Sovereign and Winsor & Newton's pencils with every satisfaction, my choice being more or less for the "Winton" pencil of Winsor & Newton.

There are more than two ways of sharpening a retouching lead, but there are only two which are really expeditious and satisfactory. One is to rub the lead on a solid block of glass paper, revolving it at the same time so that the grinding is done fairly evenly all round. To guard against breaks and to hasten the sharpening a finger tip is pressed on the lead where it rests on the glass paper. The other way, which is quicker and cleaner, is to fold a piece of glass paper and hold it in the left hand with the open edges facing the right hand. The pencil or lead, with about two inches of lead exposed, is held in the right hand, the lead pointing towards the paper. Putting the lead into the folded paper it is worked in and out rapidly and revolved at the same time, the result being an extremely fine point in a very short time without risk of breakage. The glass paper should be fine, and the piece large enough to allow the edges to be turned back over the finger and thumb. This precaution will prevent the lead stabbing one in the case of it slipping from between the folded paper when sharpening rapidly. Through using too small a piece of glass paper I once had my left thumb mottled with points of retouching lead.

The only brushes known to some young photographers are "spotting" brushes. As to just what constitutes a spotting brush they are not always very certain. The brushes sold under this title are invariably short-handled sables, similar to those used in water-colour drawing, and artists' sables are at least as good as anything for this work. Unfortunately, sables of any quality are rather dear; one can pay as much as 2s. for a single brush of a suitable size. Second-quality brushes are cheaper and good enough for most purposes. Siberians, which run about 2d. each, can be used for blocking out, except where there is very fine detail; and with skill these brushes will spot, but for regular work the sable is essential. For filling in masses of opaque when blocking out large negatives, a camel hair mop is very useful, but a common practice is to cover such spaces with gummed paper which will not rub off or abrade other negatives happening to come into contact with it. An uncommon type of brush with retouchers is the stencilling brush that is made for "Florescan" work. With this brush, paint put on to the back of a negative can be stippled or "scrumbled" into the softest of clouds or vignettes. Negatives can be built up in this way, and the printer saved much "dodging." Talking about brushes, the glass brush also has its uses. But this "brush" is more of a knife than a brush, being used for local reduction of density. Then there is the air-brush, which though not like a brush, acts as one. Water colour or dye can be brushed on the gelatine side of a glass negative or on

both sides of a film. On the back of a glass negative thin red varnish can be used if a base of matt varnish is first laid on. But varnish messes the instrument, and if it is used extra care is necessary in cleaning. When air-brushing a negative, the image should be shielded to prevent any spray from reaching it. This is necessary unless one is very expert with such work. The water colour or dye should be fairly strong and the air pressure high to get the best results.

A doubtful point with some spotters is the size of brush best suited to their work. It might appear at first sight that small brushes would necessarily do finer work, but this does not always follow. What is essential is strength and point, and these are often more noticeable in a large brush. But individual taste varies. I prefer a No. 2 for spotting and Nos. 3 and 8 for blocking out. At times I come across a No. 0 which is beautiful for delicate work, but it is not often. For edging a painted vignette, a No. 3 stencil brush is about right. Air brushes also have their sizes, and here I prefer the No. 2 "Colour Spray." A point about all brushes (and pencils, knives, etc.) is the thickness of the handle. It seems usual to make handles in proportion to the hair, lead, or blade carried, instead of to the hand, and I find many handles are too thin altogether to hold for long without inconvenience if not actual cramp. Winding such thin handles with lantern slide binding to increase the thickness of the grip results in better and easier work. I once knew an artist who stuck all his brush handles through pierced corks for the same purpose, though this would be going to extremes for anyone not possessing an obvious fist.

Some retouchers are very particular about their knives. Others seldom or never use one, and when they do their pocket-knives do duty. As it happens, this is a place where the actual instrument is not by any means so important as the skill behind it, and in the hands of an expert the pocket-knife will do better work than a first-class special knife in the hands of a novice. The Bruce retouching knife is well known, and special knives are also made and supplied by dealers; but whatever knife is favoured, to get the best from it it must be kept sharp. Not everyone can sharpen a knife to the required edge, and it may pay to have one's knife seen to occasionally by a cutler. Another factor in knifing is the state of the film. It should be bone dry, and a good plan is to warm a negative before attempting to knife it. For large patches of reduction the glass brush or a dab of metal polish on a bit of washleather will prove easier than the knife. Another dodge is to rub the negative with a mixture of methylated spirit, water, and borax. A pinch of borax in sufficient water to dissolve it is added to about three ounces of spirit, this making a very effective reducer of dry negatives. It can also be used on bromide and gaslight prints. The preponderance of spirit in the mixture precludes any wetting of the gelatine which would delay further work.

The retoucher's palette should not be limited to a piece of hard, black water colour. Lamp Black, Indian Red and Neutral Tint are all useful, and a china palette to carry them is not a luxury. Tube colours are cleaner than cakes or pans, as sufficient for the day only can be put out fresh each day. Black and Neutral Tint will cover all ordinary spotting and vignetting or working up on the reverse side, while the Indian Red is good for very opaque work such as blocking out. The proprietary articles for blocking out are too well-known to need mention here, though I may refer to one which was not primarily intended for the work but is nevertheless excellent. It is Process Black. Any yellow, orange or red dye can be used on a negative, either from a hand brush or an air-brush. Red ink is very serviceable for one. It should be remembered though, that dye is not so easily removed as paint in the case of error. When it is necessary to remove it a weak bath of sulphuric acid will often do the trick.

I have tried most of the made up mediums on the market and found them all useful. They differ in strength and "feel," but will all do the job for which they are intended. When a retoucher complains that a medium is too strong, or not strong enough, it may be that it does not suit his touch and pencil. A softer or harder pencil may be all that is required. Medium can be made fairly easily, but as there are so many kinds of rosin about, and so many qualities of turpentine and other solvents, formulæ are not very decisive. There is no harm, however, in a retoucher experimenting for him or her self if a home-made medium is desired. Good violin rosin and methylated spirit (or better still, rectified spirit) will make a workable medium. Or rosin dissolved in a mixture of turpentine, kerosene and linseed oil, the proportions of which can be varied to give differing mediums, always keeping the turps in excess of the other constituents. Gum sandarac is used sometimes in addition to the rosin, but when mixtures become complicated the question arises as to whether it is not best to buy a ready-made medium instead. Varnishes also can be bought ready for use, ordinary clear varnish being obtainable for warm or cold use. It is not so popular in these days of cheap work as it was in the past, but it has its value, and it is useful to be able to varnish a negative when necessity arrives. Matt varnish is very often useful for giving a working base on the glass side of a negative, and its use does not demand the same degree of care and skill required by clear varnish. With varnishes I will include mucilage, as this has its uses in a similar way. For undoing scratches nothing is so good as a bath of mucilage. Gelatine solution, gum arabic, Seccotine in solution, and other clear gums can be used. The mucilage should be poured into a dish, care being taken to keep out dust or other foreign matter. Bubbles also must be avoided. The negative is slid cleanly under the solution, and once completely covered it is removed as carefully and put to dry in a dust-proof place. If cleanly performed, this operaton will fill in scratches in such a way that the negative can be enlarged from by condensed light without the scratches being recorded. It is rather difficult to avoid bubbles and dust, but if the scratches are severe or numerous this method is better than tedious and perhaps unsatisfactory spotting.

In conclusion, although I have numbered many retouching implements and materials, I have not exhausted the list. But from those I have mentioned I think the enthusiastic retoucher who has not yet reached the highest pinnacle of the retouching art will be able to select a useful outfit.

THERMIT.

REAL "WHILE-YOU-WAIT" PHOTOGRAPHS.—Last Friday the editor of a Walsall newspaper received a parcel of important photographs and process blocks which were posted in Birmingham, nine miles away, in July, 1919.

A LEIGHTON BUZZARD SOCIETY.—About a score of enthusiastic amateurs met at the studio of Mr. E. J. Bacon, at Leighton Buzzard, on Wednesday evening, and decided to form a club under the name of the Leighton Buzzard and District Camera Club. It is anticipated that a beginning will be made with a membership of 30. The executive council, which was elected at the meeting, has premises in view and is at present busily engaged in drawing up a constitution and programme to be submitted to the next general meeting on the 28th inst. The secretary, *pro tem.*, is Mr. George W. Hubbard, Prospect House, Leighton Buzzard.

PHOTOGRAPHIC COMPANIES IN 1921.—The statistics of company registrations at Somerset House from January 1 to December 31, 1921, compiled by Messrs. Jordan & Sons, of Chancery Lane, include three public companies relating to photography having collectively an authorised capital of £1,116,000. In the same class twenty private companies were registered of a total authorised capital of £84,500. The major portion of the capital concerned in the three public companies is represented by that of Amalgamated Photographic Manufacturers, Ltd., registered in February last, with an authorised share capital of £1,100,000.

SECTIONAL PANORAMIC PRINTS.

[The making of panoramic prints of special subjects is work which now and again is required of a photographer. In the following article from "American Photography" Mr. C. F. Stiles tells how to use an ordinary camera for the purpose.]

The making of panoramic exposures is wonderfully simple with the Cirkut camera. This ingenious apparatus revolves on a tripod head fitted with changeable gears engaging a large gear. The detachable gears are so figured as to provide proper speed of travel of the film across the exposure slot. As the focus of the lens changes according to the distance of the objects focussed upon, the diameter of the circle travelled by the film also changes, hence the necessity of a change in film travel, since the time of revolution of the camera remains the same.

A Cirkut camera is not always at hand, and many of us do not have access to such an outfit. It may be necessary to make a panoramic view when only ordinary apparatus is available, but excellent results may be obtained by making sectional views if the photographer has a clear understanding of the principles involved.

As an example, the making of mountain range panoramas is a task we have frequently met with in the past. In winter we found great difficulty in making film exposures because of the dry cold, which produced static electrical discharges on the film whenever it was unrolled with a jerk, as is likely to happen when working under such uncomfortable conditions.

Let us assume that we are standing on a mountain summit of about 6,000 feet elevation. A line of peaks 5,500, 5,700, 5,800 and 5,400 feet high run off diagonally, so that the nearest is a mile distant and the last one about 5 miles away in an air line. The rocks above the tree line are covered with snow and ice, and the base of the mountains is cut off by the receding slopes of the peak we are standing upon.

Experience has shown us that colour-sensitive plates are an absolute necessity, and by using a deep ray-filter we can come much nearer to reproducing the visual contrast between the sky with its clouds and the snow, and also reduce the halation error. We use fast emulsions because the camera is constantly in danger of vibration from wind. The long focus lens gives us proper perspective. The more distant summits are not dwarfed by comparison with the nearer foreground, as they would be if we used a short focus lens.

The axis of revolution of the camera which a novice naturally uses is the usual tripod socket. The proper point for panoramic work is the optical centre of the lens. We meet this condition in practice by using a supplementary bed or board to which the camera is attached, with a new tripod socket under the lens itself. In the case of a double lens of the symmetrical type we find that this should be placed just under the lens, but in case of a single lens combination, it will be in advance of the lens. With a 13¾-inch single Protar the point is 15 inches from the ground glass, or 1¼ inches in advance of the lens.

To find the axis of revolution, take two smooth boards of equal width and mount the camera on one with ground glass perpendicular to the edge. On the central line of the other drive a brad up through, projecting slightly on top. Press the bottom of the camera board down on the projecting brad. You can now move the camera board on the brad point as a pivot.

Focus the camera for distance. An electric light at night is very convenient. Watch the image in relation to the vertical lines on the ground glass while rotating camera on pivot, and if there is movement, lift the board and change its position forward or backwards. By trial and error you will find the right point, and before dismantling you should locate the position of the hole to allow clamping of the camera to the board by another tripod screw.

The camera should then be permanently attached to the top board, a hole made in this board at the correct brad mark, and the tripod screw turned into the hole so as to cut a tripod socket. When the lens is replaced on the camera front, the camera is in panoramic adjustment.

With some types of view apparatus supplied with a supplementary bed one may so adjust this as to bring the lens in its proper position in relation to the tripod socket. A large tripod head gives more rigidity, and a supplementary tripod leg to brace the projecting back overhang of camera may be desirable. While adjusting the camera for panoramic work, the ground glass should be marked with vertical lines about a half-inch from the edges. This is to keep control of overlaps when planning out a sectional exposure.

With the apparatus properly mounted on the supplementary bed, focus on the left section of the view, and note the object which falls on the vertical line at the right. Revolve the camera till this object moves to the left line, and repeat to find out how many exposures will be needed. The parts outside the vertical lines are the overlaps, which we make liberal to guard against defects on the edges of negatives. We must, above all things, have the camera level, or, if impossible, be sure the greatest dip of the camera is in the exact centre of the series. Not much dip is possible if the horizon shows. Otherwise the horizon will run diagonally in the joined panorama, and we will have to sacrifice some width in trimming.

We next decide what exposure to give, as the exposures must be the same on all sections. We can occasionally change exposures, to take care of varying conditions on various sections, but this is not often possible. We find it much better to wait for an even illumination and keep exposure constant. The making of the successive exposures is an easy task, providing we look out for the overlaps, which we check up step by step on the ground glass as we turn the camera.

Development of all the sections is done simultaneously, so as to get the same printing density. This we find exceedingly important in practice. Printing we do similarly, taking one plate and making test exposures till we get the best tone rendering, after which we make a complete set, using the same printing time throughout.

The next step is to make the composite print for copying. The separate prints, which should be on glossy paper, are trimmed carefully so that they exactly match. We like to make one trim on the right edge of No. 1 (left) print, and lay this overlapping print No. 2. When the proper adjustment is made, we mark the under print on both margins with a safety razor blade. Remove the top print and, using a ruler, cut clean across the print, which will give a perfect junction. Repeat until all the prints are properly trimmed.

We have sometimes varied this procedure by tearing the prints irregularly and then rubbing down the paper back of one print till only the emulsion surface shows on the edge. This print is laid over the next one to the proper match, and so on through the whole series.

With the straight cut prints we always stain the edges of the prints which form the junctions. In copying, these come clear if they show at all, a much easier condition for retouching on the copy negative.

We next mount the series carefully on a smooth card, taking great care that the prints are properly butted together. Lately we have used Grippit, a rubber mounting solution, and this has the advantage of ease in manipulation with a minimum of stretching. It is wise to use a very heavy card in paste mounting so as to overcome the tendency of the prints to stretch and shrink.

At this point we spot prints carefully and look up some commercial artist who can put in a bank of clouds in the

sky, besides generally touching up prints. This makes the negative retouching easier.

When the composite print is done we are ready to make a copy negative. If the length of the print desired is beyond your camera capacity, you can probably get a local photo-engraver to make the negative with his large camera. The copy should be made on a slow plate, and where the original composite is made on printing-out paper, we prefer to use an ortho plate and copy with a filter and incandescent electric lights.

The resulting negative can be very effectually modified by flowing some ground glass substitute on the back and strengthening here and there with pencil or crayon.

We took a mountain panorama as our first example because no very near objects are included. The conditions change with very near foregrounds, and here is where the long focus lens has its advantages. When such a condition is met with, we must elevate our lens by the rising front so as to cut out very near foreground. Always avoid long straight lines very near the camera. These will be rendered with different angles in each section, whereas in a Cirkut view we get a constantly changing curve. As the line becomes more diagonal, the distortion effect is lessened.

In distant views made with film cameras, we can sometimes cut the negatives themselves and make a copy negative or an enlargement by projection. In many cases the enlarging process is better and retouching on the enlargement is easier because the treatment can be broader, due to the fact that big prints must be viewed at a greater distance.

Those who do not wish the trouble of making a copy negative sometimes get a picture framer to make a multiple opening cut-out for the various sections. This is a very effective treatment. Care should be taken that the colour of the cut-out harmonises with the print, as some injudicious selections we have seen seem to degrade the brilliancy of the pictures.

With a 7 × 11 view camera we can do some novel stunts, because of the convenience of the sliding lens board. We have in mind one task in photographing a very long group of buildings which could not be taken, even with a very wide angle lens. The temporary clearing of a lot in front of this building gave a free outlook, but the distance we could go back was limited. We found a pile of boards situated conveniently near the centre of the view, giving us a high elevation, so we could cut out the rubbish and cellar pits of the foreground.

Our camera was set up with the plate parallel to the front of the buildings, and by sliding the lens to the limit each way we could catch both ends of the building. Two plates were made, and a vertical line on the building was selected as the cutting point. The joined print, when retouched, was not copied, but used direct as an original for reproduction.

At another time we had occasion to photograph the same group from the roof of a building down the street. The great length of the building along the street we were on made the far end very small in comparison to the nearer parts, while the end of building on the cross street came just the right proportion. We were equipped with a set of convertible single lenses, and used one of quite long focus, with which we made an exposure on the long façade. An enlarged negative of the first plate was made with the corner of building exactly the same height as on the long focus exposure. Junction was made at this point. A building on the opposite corner obscured the lower part of the end exposure, but this was blocked out with Chinese white, and the commercial artist handling the retouching very skilfully faked the hidden windows, as he had enough window ledges showing to get the inclination of perspective lines and the details of construction.

Such work as the above is limited only by the ingenuity and imagination of the worker. The actual task of making a matched series is really very simple with a little practice.

C. F. Stiles.

THE PRACTICAL STEREO PHOTOGRAPHY OF SMALL OBJECTS.

The insertion of the word "practical" into the heading of this article calls for a considerable amount of courage, for no study of this baffling problem can be said to have reached a practical stage until it has provided the photographer with a few simple working instructions or formulæ whose accuracy he can put to the proof as easily as he can test the optical properties of a lens of whose construction he knows nothing. A previous conscientious investigation, on geometrical lines, cleared the ground fairly thoroughly, so far as the theory is concerned, but it left a good many hard fences for the man with the camera to get over before he could reach his goal. It is our present object to remove these difficulties altogether, so far as may be, and to present the matter in a form that will allow the skilled and careful worker to obtain exact results by direct exposure without having to carry out a series of vexatious manipulations of his negatives and prints. The photography of small objects always calls for skill and care, and there is therefore an irreducible minimum of trouble which must be faced. It is on the worker's technical and artistic skill that success will ultimately depend.

A few preliminary observations are necessary in order to define, once for all, the object of our search. It is the photographer's desire to be able to present stereoscopically an image on a certain scale, n, and at a certain distance, x, n and x being variable at his pleasure—say that he wishes to show a small entomological specimen magnified 5 diameters at a distance of 12 in. This obviously takes it for granted that size and distance may, in a real sense, be attributed to the image; otherwise the whole project becomes nonsensical. It will be more absurdity to attempt to measure the width of a mental impression—if that is all we can obtain—in inches and decimals of an inch, as we shall have to do in every case if we are to arrive at any degree of accuracy. The image must, therefore, be assumed to be real, so far as the eyes are concerned, with a definitely measurable size and distance.

The first indispensable condition that must be fulfilled, if this sense of reality is to exist, is that the light should enter the eyes from the various points of the image as from the points of a real object, *i.e.*, that the eyes should be *focussed* and *converged* exactly as in nature, upon the points in space which a real object would occupy. We are setting out in search of a simple, practical method by which such perfectly projected images can be obtained.

The second indispensable condition is that the image should not be presented to the eyes in a way that makes it impossible for the mind to accept it as true. The photographer, here, as always, has two tasks before him: first to perfect his technique, and then to find a perfect medium by which his results may be expressed. The two media with which we have to deal in this case—the two things that come between the observer and the image, constituting a kind of physical obstacle through which he has to project his mind—are the stereoscope and stereo print. There may be individual workers who have a lively perception of the importance of this part of the prob-

...; but it is employing very mild language to say that, as ... known, the stereoscope generally used, and the prints generally furnished, are hardly conducive to accuracy and interest.

The stereoscope almost universally offered to purchasers consists of a squinting, open-frame contrivance, having two segments of large diameter lenses, mounted with their axes inclined to each other, adapted, no doubt, to allow incorrectly mounted prints to be examined without causing brain fever. Wonderfully cheap and efficient, this appliance is ready to accept anything that is presented to it, and make the best of it. It is an old and valued possession of many a stereo enthusiast, which we must not criticise too harshly. But it will be pure waste of time to aim at technical precision, or even to expect any definite result at all, if the prints are to be submitted to a contrivance of this kind. Again, the open frame allows a multitude of other objects to thrust themselves upon the observer's notice in addition to the image; portions of the woodwork of the stereoscope, brightly illuminated; large areas of the room and its furniture; two secondary images—veritable ghosts—one on each side of the true image—all these create a chaos of confused impressions covering the whole sensitive surface of the retina, in the midst of which it is idle to expect the image to assume any aspect of reality. The stereoscopic image is necessarily a very frail thing. Unlike other realities it is dependent upon one sense only, and that only a fixed glimpse from a single point of view; we cannot verify our impressions by moving about and looking at it from a different angle. To project this image, with its more than soap-bubble delicacy, into open space, where it has to rub shoulders with the crowding images of solid objects about us, is somewhat like hanging a canary in a boiler factory in the hope of enjoying its song. There is a clear demand for a box-form stereoscope, with an efficient central partition reaching right down to the surface of the print, so that nothing is visible to the eyes except the true stereo image. The outer end should be closed with a matted glass diffuser for viewing transparencies, and a small door on top, carrying a mirror on its inner surface, would allow ordinary prints to be examined by reflected light. The whole interior should be dead black, and focussing should be at the eye end. This is one of the oldest forms of stereoscope, dimly remembered by the writer from the days of wet-plate photography. It makes a not unpleasing addition to the furniture of a room, and it should be comparatively inexpensive to manufacture.

The stereo prints are usually mounted or made on a white background, which is often highly glazed, and the white border thus left dazzles the eye with its brilliance. This, together with surface reflections, makes it impossible for the observer to forget that he is merely looking at the surface of a flat photograph, possessing some peculiar characteristics which give an impression of perspective relief. The writer had made many dozens of stereo prints before he discovered the virtues of a dark-green mount and a printing paper of smooth but not shiny surface. Even at its best, however, the mounted print can never be a perfect medium, and there is a clear call for the use of transparencies such as more than forty years ago gave wonderful beauty and reality to the stereoscopic image. The great difference in the quality of reflected and transmitted light is not generally recognised. People as a rule are sceptical when they are told that the image of an ordinary candle photographs white against a brightly sun-lit whitewashed wall—that the direct rays of the candle are stronger than the reflected rays of the sun; but the truth of the statement can easily be verified by experiment. Transparencies have the advantage that they not only allow the interior of the stereoscope to be kept in complete darkness except for the light entering through the prints, but they bring this great *compelling power* of direct rays to the eye of the observer. The old difficulty about storing glass transparencies may perhaps be overcome. The flat film, and still more the roll film of to-day, would seem to open out new prospects very tempting to the progressive worker.

There is a third indispensable condition over which, unfortunately, neither the photographer nor the observer has any control. The observer must have good sight. *Realisation* of the result will depend upon acuteness of vision and the sensitiveness of the eyes to variations of distance. When the object photographed is a familiar one and the image is natural size a very powerful aid is given to the observer's judgment. The contents of the image then allow it to tell its own tale, and the mind will readily place it at its proper distance. But when the image is magnified, or is of some object unknown to the observer, the eyes alone have to perform the work of placing the image and deciding its actual size. As the sensitiveness of the focussing and converging accommodations of the eyes is only acute for near distances, and as the difficulty of precision in technique becomes greater for distant images owing to the minuteness of the changes in the prints, these considerations put a practical *space limit* upon success, unless, as stated above, the contents of the image guide the mind to a conclusion. In no case must anything appear that would mislead the eyes, for the mind cannot accept the reality of that which it knows to have no existence. Between the limits of 12 in. and 20 in. there should be, for people with normal vision, a very vigorous estimation both of size and distance, quite independently of all previous knowledge of what the image represents. If too long-sighted or too short-sighted, the observer will not be able to see an image distinctly at, say, 12 in., and he will have to shift the focus of the stereoscope from its proper position. The convergence of the eyes on the points of the image will, however, remain practically undisturbed, and the loss of reality should be no greater than that which results from the wearing of glasses. The children of the family, with their young and flexible sight and unsophisticated minds, will be the best judges of the photographer's success. The tired sight of old age can hardly hope satisfactorily to address itself to the task.

We have had to detail the practical difficulties in a rather discouraging manner—difficulties that are quite external to the photographer, and lie altogether outside the technical and optical part of the problem with which alone the writer is competent to deal. A false optimism here would lead to deceptive theory, and would only result in so disappointing the worker as to cause him to abandon the attempt as hopeless. The drawing up of long tables giving precise distances and sizes of the stereoscopic image beyond the limits to which *under present conditions* they can be realised, without adding a warning notice, is a kind of dishonesty particularly abhorrent to mathematicians. To what degree then may we hope for success? So far as technical accuracy is concerned; so far, that is, as regards the taking of the negative, the preparation of the prints, and the projection of the image, it may be stated with confidence that precision can be attained, and that the inevitable small errors due to mechanical causes will not affect the results in any appreciable degree. The procedure about to be recommended is based upon two elementary and long-established formulæ relating to lenses—one dealing with the photographic lens and the other with the lenses of the stereoscope. It has been verified by innumerable cross references and test cases until no room has been left for doubt. The only assumption made is that the lenses in both cases give rectilinear images and have a flat field. Technical success is therefore certainly within our reach; success itself, within practical limits, which experiment will soon decide, will depend upon the way in which the results are presented to the observer and on his power of visualising them. These limits may be much wider than the writer anticipates. There seems to be no reason why the photographer should be content until by a happy alliance of exact technique and perfect medium he succeeds in producing an image that forces itself upon the mind with a compelling sense of reality.

It will be necessary to tax the reader's patience with a little theory, sufficient to serve as a slender thread connecting the various steps by which we arrive at the working formulæ. Perhaps, therefore, while the dish is a preparing, it may be well to give the worker a bone or two to go on with, in

the shape of some concrete examples of what can be done. Let us turn then abruptly to the photographer's work-room and see with what apparatus he must provide himself. The list is not a long or formidable one.

(1) The optical data given by the stereoscope have such a dominating influence upon the taking of the negatives and the preparation of the prints that no progress can be made in tabulating possible results until a decision has been reached with regard to the focal length of the lenses to be adopted and the separation of the lens centres. For present purposes, therefore, the writer, after some hesitation, has tentatively standardised a stereoscope having lenses of 4 in. focal length, with their centres 2½ in. apart. This gives an image subtending, from side to side, an angle of about 35 deg. with the eye, which will probably be regarded as a pleasant and sufficient field of view. The covering power of the lenses must be considerably greater than this—between 60 deg. and 70 deg.—as for nearer distances of the image the prints will be decentred, and they should have a clear viewing aperture or diameter of not less than 1¼ in. The focussing adjustment must allow the distance between lenses and print to be varied from 3 in. for images at 12 in. to 4 in. for images at infinity, *i.e.*, for landscape prints. Abnormally short-sighted observers will require an adjustment to a distance of less than the above 3 in., which should be provided, if possible. The details of construction must be left entirely in the hands of the practical optician. The actual width of the two prints mounted side by side will never exceed 5 in., and the height, which lies at the worker's discretion, will probably not be greater than 3 in., so that a postcard size print holder would be ample. This stereoscope has the advantage that it is eminently suited for viewing landscape prints taken with a 4-in. lens, and would remove the necessity of having two or more appliances for different purposes.

It is to be hoped that the provision of the above stereoscope will not be too grave an obstacle in the worker's path. In order to be useful effectively, there is no choice but to decide at the outset upon the exact optical details of this instrument to which, in a most real sense, we have to *submit* our prints, and by whose judgment we must abide. If a stereoscope of too long focus is used, the image, unaltered in width, is projected to a greater distance, and its depth is increased. It is opened out somewhat after the manner of a concertina. If the lenses are too far apart the image is brought nearer, made smaller, and distorted. If both errors exist simultaneously the result is utter confusion, and the precise care given to the taking of the negatives is rendered nugatory.

(2) Happily no such restriction is imposed upon us with regard to the next piece of apparatus—the camera. Any small accurately constructed camera with focussing adjustment will do; it need not be greater than quarter-plate, and may be 3¼ by 2½ if the longer side is placed horizontally. Unfortunately this latter size is just too small to allow of its being used vertically, as the decentring of the right and left images on the focussing screen brings one edge of each image right to the edge of the plate. Careful use of the sliding front would obviate this; but it will be far safer for the worker, and especially for the experimenter, to avoid this dangerous complication, which is very liable to lead to error. From the time the camera is focussed on the object and adjusted for the first exposure it is better to regard it as a rigid body, and simply to shift it as a whole parallel to itself through exactly the required distance before making the second exposure. This movement of the camera rather than of the lens alone reduces the amount of sideways shift of the negative on the plate, since plate and lens both move together, and allows a smaller size to be used. When lenses of exactly the correct focal length are available the extension of the camera will never be greater than 4 in., and never less than 3 in., no matter what may be the scale and distance of the required image; but when for convenience lenses of only approximately correct length are used these limits may be slightly exceeded. In photographing very flat objects, such as old coins or medals, it may be desirable deliberately to exaggerate the depth of the image in order to gain greater relief, and in this case a shorter lens would be used—perhaps of only half the calculated correct length—and the extension of the camera would be correspondingly decreased. The above particulars as regards the camera cover not only the few examples about to be given, but the whole infinite range of possible stereoscopic results.

(3) For the following examples a 2½-in. lens will be required This is made to do the work of a 2.4 in., a 2.66 in., a 2.29 in., and a 2.22 in. lens., and the results are therefore approximate. A slight error in the depth of the image is introduced, but the difference is so small that it may fairly be described as negligible. This power of getting practically accurate results with any lens which approximates to the focal length indicated by the formulæ is of great importance, provided it is not pressed too far. It should be kept rigidly within limits so small that it is impossible for the observer to detect distortion.

(4) There is yet one more piece of apparatus the arrangements of which must be left more or less to the ingenuity of the worker. Its object is to give definiteness and precision to his operations just where these qualities are most necessary and most difficult to attain. Some small object is about to be photographed—say, a 2-in. or 3-in. cube. It has to be placed at a certain distance in front of the lens in order that the perspective may be correct; and the resulting negatives must be on the exact scale required for the stereo prints. But what, photographically, is the *width* of this cube when it is placed somewhat diagonally to the camera, as it should be? And, since its nearer points and its farther points are at different distances, what is to be taken as the working distance? And how is it to be known, by inspection of the focussing screen, whether the negatives will be on the proper scale? These questions really form the crux of the photographer's task, which becomes increasingly difficult when the object is not geometrical. The arrangement about to be described removes all uncertainty as regards width, distance, and scale, and, at the same time, clearly marks out on the negatives the exact boundaries along which the prints are to be trimmed before being mounted side by side. In its best form perhaps the apparatus consists of two vertical hanging cords, weighted at bottom and slidably suspended at top from a horizontal rod so that the distance between them can be exactly adjusted to correspond with a measurement which in every case is given by the working formulæ. Oscillations in the cords will be effectually damped out by allowing the weighted ends to dip into water, or, still better, into thick oil. Or two long straight knitting needles or lengths of Stubbs' wire may be fixed vertically into small feet or supports, so that each wire and its supporting base looks somewhat like a capital L. Two round-headed screws under the wire end of the base and one screw at the other end will allow the whole to be adjusted until the wires are perfectly vertical. They can then be readily moved about on any flat surface until the distance between the wires is that required by the formulæ.

H. C. Browne.

(To be continued.)

Finger-print Photographs by X-Rays.—The experts attached to the French police propose to employ X-rays to help in the taking of finger prints. "La Nature" gives some examples of the work, and says that instead of with ink, the finger tips will be coated with a salt, such as carbonate of bismuth, which makes a print on an X-ray negative similar to the old print on paper, so that when the negative is developed there will be a perfect picture of the whorls on the skin as well as of the bones and the outline of the finger nails. This amplification of the ordinary Bertillon method gives added means of identification, the shape of the nails and the bones being individually as different as the patterns formed by the whorls on the skin.

THE P.P.A. 1922 PROGRAMME.

THAT objection would be taken to the date fixed for this year's Congress was within the expectation of the Executive, and at a recent meeting of the Council it was decided to place on record, for publication, the reasons for the change from spring to autumn.

It has been growing evident year by year that the space kindly allotted to us at the Horticultural Hall was insufficient for our growing needs, and that unless larger premises were obtained the old and friendly partnership with the management of the Fair would have to be dissolved. When the offer of the usual accommodation came along, the whole question was anxiously and carefully considered from all points of view, and it was rightly decided that the space offered was insufficient, and with regret the decision was made to strike out, and find rooms for ourselves elsewhere.

For a change of policy, could any time be more appropriate than the coming of age? The year 1922 is the twenty-first anniversary of the formation of the P.P.A.—an association "doomed to extinction" (as was said a year afterwards), a prophesy in no sense fulfilled.

A sub-committee was immediately formed for the purpose of finding rooms, and a number of picture galleries were visited, but nothing suitable was procurable in the months of spring, and only two had vacancies in the autumn. Consequently the question was laid before the Council, and it was decided to fix upon those rooms obtainable at the latest time in the autumn. By good fortune these proved to be Prince's Galleries, Piccadilly, in every way the most convenient for our purpose, and available from September 11—13 inclusive. The rent for these splendid rooms will not be in excess of last year's cost of furnishing with screens, etc., the picture exhibition room at the Royal Horticultural Hall.

It will now be possible, and it is intended, to hold an international exhibition of professional work, and already some American leaders have notified their intention to exhibit.

The Congress itself will be run upon much the same lines as hitherto, except that the social side will have more attention paid to it than has been possible in the past, and new features of interest are to be introduced. There is plenty of space for demonstrations and lectures, and it is anticipated that not only our own countrymen but masters in the art from other lands will be invited to attend. Manufacturers will be accommodated with space for trade display.

That the date chosen will be inconvenient to seaside photographers was suggested, the "pros and cons" were thoroughly discussed, and, upon looking into the matter it was found that last year, with a paper membership of 1,300, only 30 came up from seaside towns, 7 from spas, viz., Bath, Tunbridge Wells, Harrogate, etc., and 230 from London and provincial towns.

It is fair to conjecture that with the alteration of date, the proportion of visitors from the coast will not be smaller, and that with the attraction of a coming of age celebration the comparatively small attendance will be increased, and the later date may even suit those from spas better still. It will be found that the usual photographic exhibitions open their doors somewhere about the date of our Congress.

Members will shortly be having in their hands a copy of the annual report, and they will see that the past year has been a busy and important one. The incorporation of the Society has necessarily thrown much extra work upon the Council, for many matters of vital importance in the interests of the Association had to be decided. It is well that this business is now completed, for registration is greatly to the advantage of the individual member; her or his liability is restricted to the small sum of 10s., the amount of the annual subscription.

It is perhaps well to remind members that this important step was approved at the annual general meeting held at the time of the 1921 Congress, and again confirmed at a special general meeting, to which all members were invited by circular. It is impracticable at present to supply members with a copy of the Articles, but they will be available at a later date

Now that this matter is accomplished, the P.P.A. Circular, or a magazine to take its place, will be re-established, and that broken link between Council and member repaired, much to the satisfaction of all concerned.

It now only remains to be said that the launch out from the old, and now inconvenient, arrangements at Vincent Square encourages the Council to look forward with confidence to the whole-hearted support of the members, in the belief that they will do their share towards making this coming celebration a record success, a Congress worthy of the Association and an event that all interested will be proud of.

On behalf of the Council.

LANG SIMS, Secretary

Exhibitions.

CAMERA PORTRAITS, BY WALTER STONEMAN, F.R.P.S.

THIS is one of the most interesting occasional exhibitions that the Royal Photographic Society has given the professional man for many months. If to be able to show a distinguished clientele of stars is an augury of prosperity in business, then Mr. Walter Stoneman should feel content, for he displays a perfect milky way of Men of Mark. He evidently has the grand secret. The galaxy ranges from royalty itself to the trade-magnate. Out of 81 portraits only five are plain esquires; all the rest have handles to their names. There are "noble dukes and belted earls," soldiers, sailors, apothecaries, in uniform; but for the tinker, tailor and ploughboy Mr. Stoneman has no use; though he admits an occasional "pale young curate." Even one or two painters by reason of their knighthood have become eligible for inclusion in this dazzling array of wealth and honour, of which the flavour is more of Debrett than of "Who's Who."

Mr. Stoneman believes in standardisation. His prints are all more or less of the same area that accommodates liberally a life-sized head; and the effect, upon first coming into the room, is not a little imposing—such a mighty row of bright heads on black backgrounds! One immense enlargement, and a few smaller prints in groups, break the monotony of this well-groomed, highly respectable company.

There is a good deal to be said for this standardising—for its effect in an exhibition, at least. A client can rely upon getting what he sees in the window. It is a special commodity: a head and bust about life size, with a straightforward lighting that makes silvery hair and spotless collars gleam out from the dark backing. The contrast undoubtedly makes for force, and that can be counted upon for captivating all classes.

Side by side with the "tities and orders" and the smartness of appearance, there is the no less popular attraction of smooth texture. Shadows melt into lights with a sweetness of gradation that never fails with the great B.P. In some cases, however, there is evidence that the retoucher has been spared, for a clear demarcation of sculptors' "planes" has been allowed to assert itself. This is noticeable particularly in No. 51, Sir Adolphus Ward, Litt.D., and The Lord Pentland, G.C.S.I. (52). These have a scheme of light and shade that is significant, and a human skin-texture rather than an egg-shell gloss. Others that stand out as examples, either of animated posing or of lively expression and character, are the Rt. Hon. D. Lloyd George, O.M., M.P.—the Premier at his best, without the cinema smile—The Lord Ribblesdale (9) in a silk hat (he was painted by Sargent in a silk hat), Field-Marshal the Viscount Allenby, G.C.B. (10), who has a martial bearing in spite of mufti, and Sir D. Murray, R.A. (15), which has both character and effective light and shade.

The Hon. Sir C. A. Parsons, K.C.B. (17), has a countenance that lends itself to good pictorial results. His portrait appears in two versions, one of which is in the illustrated catalogue; and this, to our minds, has the better turn of the head. One of the most interesting character studies is the portrait of the Bishop of Winchester (29). It is entirely free from that episcopal self respect that usually appears in the pictures of Bishops. Another very happy likeness, and one of the best achievements, is the thoroughly spontaneous Bernard Shaw, Esq. (32). With less of bravado, but quite as much convincing character is Sir J. J. Thomson, O.M., F.R.S. It is one of those examples in which the edges of the planes of modelling have not been beautified away.

In a few cases the assumed life-size has come out in the enlargement as a little under life-size; and this, we think, is a misfortune from more than one point of view. It certainly robs the subject of that monumental nobility and dignity which portraits like these should possess before all things. And in a gallery where a lot are shown together it is disconcerting to glance from one to the other and find the scale changing from large to small. Nos. 62, 63 and 64 is a group where the centre picture is possibly larger than life, whilst those that flank it are dwarfish; not small enough to be safe from comparison with the full scale.

The most pictorial portrait of all is that of Gen. Sir R. Baden-Powell, K.C.V.O (60). The General is rightly wearing his Boy Scout hat, which receives the full flood of a top light. Since Baden Powell equals Boy Scout in ordinary association of ideas, this prominence of the hat supplies an appropriate idea. The face beneath is in shadow for more than half its length; yet the whole effect is good and artistic. F. C. TILNEY.

FORTHCOMING EXHIBITIONS.

January 11 to 27.—Camera Portraits, entitled "Men of Mark," by Walter Stoneman, at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1.

January 21 to February 4.—Partick Camera Club. Particulars from the Hon. Secretary, James Whyte, 51a, Peel Street, Partick, Glasgow.

February 7 to 11.—Sheffield Photographic Society. Latest date for entries, January 21. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield.

February 11 to 25.—Scottish Photographic Salon. Latest dates, entry forms, January 23, exhibits, January 31. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Latest date for entries, January 30. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Latest dates, entry forms, February 4; exhibits, February 9. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Latest dates: Entry forms, February 8; exhibits, February 22. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 6. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 26.—Welsh Salon of Photography. Latest date for entries, March 9. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1

September 18 to October 28. Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 3 to 7.

PRINT CLIPS.—No. 538. Clips for suspending photographic prints, etc. A. C. Andrews.

SENSITISING.—No. 294. Sensitising film and paper. F. W. Hochstetter.

EMULSION.—No. 289. Sensitive positive emulsion for photography and process of making the same. F. W. Hochstetter.

EMULSION MAKING.—No. 291. Sensitive emulsion and process of making the same. F. W. Hochstetter.

TRANSLUCENT MEDIUM.—No. 293. Manufacture of translucent medium for photography. F. W. Hochstetter.

TRANSLUCENT MEDIUM.—No. 290. Translucent medium for photography, and process of making the same. F. W. Hochstetter.

PRINTING MACHINES.—No. 484. Photographic printing machines. E. Sankey.

ALBUMS.—No. 12. Film or photograph album. B. M. and C. S. Grace-White

COLOUR PHOTOGRAPHY.—No. 42. Interchangeable focussing screen for colour photography. G. C. B. Saw.

PROJECTION MECHANISM.—No. 292. Mechanism for projection of light. F. W. Hochstetter.

PROJECTION METHOD.—No. 128. Method of producing visual depth in projected pictures. T. H. Marten.

COLOUR PROJECTION.—No. 392. Apparatus for producing photographs and projecting them in natural colours. L. Rottenburgh.

STEREOSCOPIC COLOUR CINEMATOGRAPHY.—No. 391. Apparatus for producing stereoscopic moving pictures in natural colours. L. Rottenburgh.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DRY-MOUNTING PRESSES.—No. 172,470 (October 6, 1920). The press is made as usual with a base 1 having two pilars 2, 2 surrounded by helical springs 3, 3 which carry the heated press box or platen 4, this in turn being depressed by a plunger 5 fitting in the arm or cross girder 6, and operated by a cam 7 on the handle 8. The goods to be operated upon are placed between the base 1 and the heated press box or platen 4.

In such construction, should a greater number of sheets be inserted between the base 1 and the press head or box 4 than

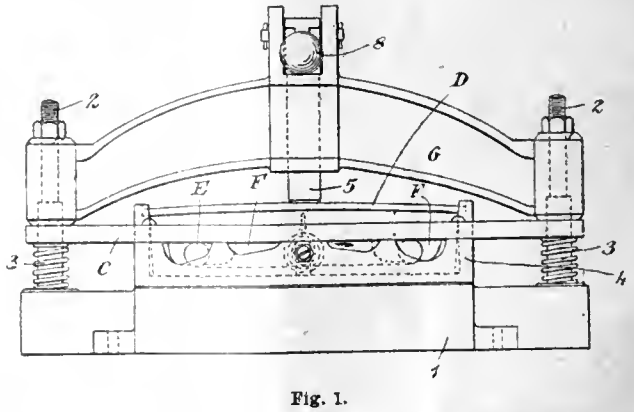

Fig. 1.

the proper working of the press will allow the operating handle 8 cannot be moved its full distance and any extra power put upon the handle 8 to move it its full distance will cause the plunger 5 to have such action upon the platen 4 that it invariably splits or breaks the latter rendering the machine useless until a new box is fitted to the machine.

The object of the invention is to so construct the heated platen that it is strengthened, and also to provide means whereby (even should more than the proper number of sheets be inserted) an extra pressure put upon the handle will not in any way injure the machine or split the heated platen.

For this purpose the heated box or platen 4 is constructed with webs A to strengthen it where most liable to be broken through excess pressure and on two extreme edges of the heated platen two vertical projections B, B are constructed, these projections passing through oblong slots which are made in the cover C of the heated platen 4 which is secured to the box 4 to receive the projections B, B.

Fitted between and resting on the projections B, B a plate spring D is fitted, or any other form of spring may be fitted, the

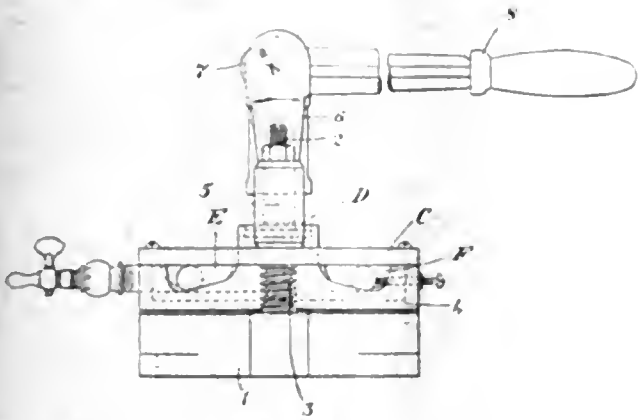

Fig. 2

centre of the spring D being placed immediately under the plunger 5.

The result of this is that the pressure when applied as the plunger 5 moves down instead of being in the middle of the heated platen 4 is distributed over the whole surface, and is therefore not so liable to crack the heated platen 4.

When in operation with the correct thickness of material in the press the plunger 5 acts on the spring D and moves it with the head comprising the box 4 or cover C to effect the desired pressure and without materially flexing the spring D. But should more than the proper quantity of sheets be inserted any extra pressure on the operating handle 8 will, after the press

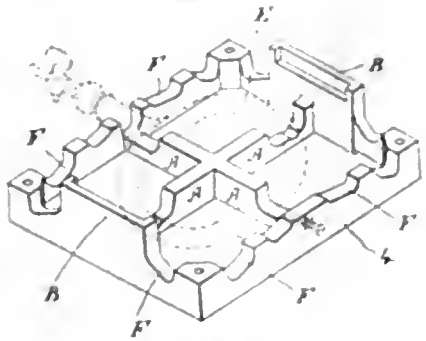

Fig. 3

head has effected its proper pressure, act upon and flex the spring D and so the handle 8 can be moved its full distance without injuring the machine or sheets under treatment, and the heated platen 4 will not be injured owing to the pressure being more evenly distributed and maintained.

The box head contains the gas burner E; as is usual the upper edges of the sides of the box 4 are formed with recesses F to allow of escape of the products of combustion.—Percival James Burrell, 569, High Road, Tottenham, London, N.17, and John Joyce, Imperial Works, White Hart Lane, Tottenham, London, N.17.

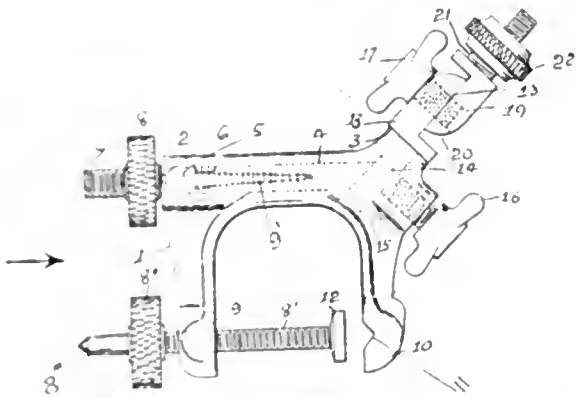
CAMERA SUPPORTS.—No. 172,775 (September 30, 1920). The invention is a frame of U-pattern to which a camera can be attached, whilst the frame is fixed to some support such as a tree or post.

1 is the frame formed approximately U shape and carries the projecting pieces 2 and 3. The limb 4 of the U is bored or otherwise hollowed out as indicated by dotted lines and screw-threaded at 5 to receive the screw-threaded part 6. Such part 6 consists of the screw-threaded portion 7 rigidly carrying at or about mid-length the grip piece 8 consisting of a disc preferably knurled or milled at its periphery, the portion 7 carrying at one end a screw-threaded part 9^1 which latter part is preferably formed taper and provided with screw threads of the wood variety.

The screw-threaded part 7 is adapted to engage with the screw threads 5 formed in the limb 4. 8^1 is a screw-threaded shaft which has free screwing movement in the U limb 9 in order that when such shaft is rotated in one direction it recedes from the U limb 10 which is preferably furnished with the recess 11, this recess being provided for receiving round or irregularly shaped articles, such as walking sticks, to which apparatus for the time being is clamped, and when rotated in the other direction moves towards the limb 10.

The shaft 8^1 is furnished with the means for its rotation, preferably consisting of the milled disc 8^{11} rigidly secured to the shaft 8^1, and also with the disc 12 rotatably secured thereto.

The frame may be secured to any suitable support by squeezing the support between the recessed portion of the limb 10 and the disc 12 by the rotation of the shaft 8^1, or it may be secured to a support such as the trunk of a tree, by screwing the part 9^1 into such support. In this latter case the part 6 is removed from the position it occupies, as shown in fig. 1, and being reversed the part 7 is screwed into the threaded part at 5, with the result that the part 9^1 projects from the frame, thus enabling the part 9^1 to be screwed into the support, and at the same time shaft 8^1 is rotated in the direction which causes part 12 to recede from the



recessed portion 11 of limb 10 until the extended taper portion 8^{111} reaches the tree trunk or any support the screw 9^1 happens at the time to be attached to in order to give the apparatus more stability.

13 is a part formed as shown with a spigot 14, such spigot having free movement in the boring 15 in which it is held in the desired position by the set screw 16. Hinged to the part 13 by means of the set screw 17 passing through the plain perforation 18 in the part 13 is the swinging part 20, the set screw 17 screwing into the screw-threaded perforation 19 in the part 20, thus holding the parts 13 and 20 together in any desired position.

The part 20, as will be seen, rigidly carries the part 21, formed with two diameters both of which are screw-threaded, the larger diameter carrying the nut 22 to operate as a lock nut to the object supported, which is secured to the smaller diameter of the part 21.—Edward George Pyne, 26, Queen's Road, Beckenham, Kent, and The Monarch Engineering Company, Ltd., 141, Sydenham Road, Sydenham, S.E.26.

The following complete specifications are open to public inspection before acceptance:

PROJECTION APPARATUS.—No. 173,497. Method of and apparatus for producing pictures by projection. H. A. Smith and E. J. Marston.

COLOUR REPRODUCTION.—No. 173,509. Method and apparatus for reproducing in colour paintings, drawings, or prints and the like. G. Piccioni.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

NOVEX.—No. 418,671. Chemical substances used in photography, photographic plates, and photographic films. Kosmos Photographics, Ltd., Balfour House, Finsbury Pavement, London E.C.2, and Pixmore Avenue, Letchworth, Hertfordshire, manufacturers.

New Materials.

Vittex Rapid Gaslight Paper. Made by Gevaert, Ltd., 115, Walmer Road, North Kensington, London, W.10.

MESSRS. GEVAERT have added to their numerous development papers one which yields rich warm black tones directly in the developer. This new paper, Vittex, is intermediate in speed between bromide and gaslight, that is to say, it is several times as fast as the average gaslight paper, and is thus of a speed which is convenient for commercial work without the necessity of very special equipment as regards power of light in the printing box. An idea of its sensitiveness is given by stating that the exposure required by an average negative, 12 inches from a 50-c.p. lamp, is about 10 seconds. While, of course, there is no insuperable difficulty in increasing the light in a printing machine in correspondence with the slowness of a printing paper, the convenience of the considerable speed of Vittex will be appreciated by those wishing to use a paper of this kind with the least possible disturbance of the ordinary working conditions.

Any ordinary developer may be used, but the makers recommend one or other of the following:—

For Soft Negatives.

Metol	13 grs.
Soda sulphite, cryst.	1 oz.
Hydroquinone	50 grs.
Potass. carbonate, cryst.	2 ozs.
Potass. bromide	8 grs.
Water	20 ozs.

For Strong Negatives.

Metol	25 grs.
Soda sulphite, cryst.	¾ oz.
Hydroquinone	8 grs.
Potass. carbonate, cryst.	1 oz.
Potass. bromide	8 grs.
Water	20 ozs.

A fairly strong negative appears to be the best for Vittex, but by using the first developing formula prints of quite satisfactory vigour are obtained from negatives which would be regarded as distinctly soft for a normal printing paper. The user can, if he likes, mix the two developers together in any proportion for the purpose of making prints of just the degree of vigour which he fancies.

Vittex prints come up quickly in the developer, and development is complete in from 40 to 60 seconds. The time of development is perhaps the only item in the handling of the paper to which it is necessary to give particular attention in order to get the best results. Prints should be exposed so that they are not too dark after 40 seconds' development, nor too light after remaining for a minute in the developer. The user must not expect to force an under-exposed print in development, or snatch out one which has been over-exposed, and at the same time obtain the fine colour and gradation yielded by the paper under proper treatment. Fixing is done in an acid bath consisting of hypo and metabisulphite.

The colour given by the paper is a rich warm black with rather more brown shade in it than some other papers of this type which we have used. Its characteristic colour quality shows to the best advantage in the cream varieties, sold as "Chamois," the results on which are of a specially artistic character. As regards the gradation, the prints show exceedingly good rendering in both the light tones and the deep shadows, and complete purity of the high lights. The makers have evidently made good use of their long experience in the manufacture of emulsion papers in uniting the qualities of their earlier grades with the production of a warm black colour.

The Vittex paper is issued in no less than twelve different varieties, six white and six cream. These represent glossy, semi-glossy, matt and fine grain surfaces and include also card weights. The photographer must be difficult to please who cannot find among these grades one which answers his special requirements. The "Chamois" matt smooth (No. 7) and "Chamois" fine grain (No. 10) appear to us as two of the grades particularly to be recommended for studio portraiture, but the other grades, both "Chamois" and white, have distinctive fine qualities. We are quite sure that professional photographers will be anxious to make the acquaintance of this notable addition to the Gevaert papers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 23.

Bradford P.S. "Elementary Bromide Enlarging." Wellington and Ward.
City of London and Cripplegate P.S. "The Printing of Bromide Papers." N. F. Horne.
Dewsbury P.S. Y.P.U. Portfolio.
Kidderminster P.S. "Odds and Ends." Dr. Landon.
Leeds Camera Club. Demonstration Competition.
Southampton C.C. "From the Cape to Zambesi." B. J. Simester.
South London P.S. "Personal Practice in Lantern Slide-making." H. Pickwell.
Wallasey A.P.S. "Fosses and Fjords of Norway." J. Mansell.
Walthamstow and Dist. P.S. "Gaslight and Bromide Contact Printing." E. Willcocks.
Birmingham Phot. Art Club. "Lenses, their Uses and Abuses." W. T. Comer.

TUESDAY, JANUARY 24.

R.P.S. "The Plate and the Photographer." C. M. Thomas.
Birmingham Phot. Soc. R.P.S. 1920 Competition Slides.
Dennistoun Amateur P.A. Whist Drive.
Exeter Camera Club. "Carbon Printing." F. G. Tutton.
Leeds P.S. "The Romantic in Landscape." F. C. Tilney.
Morley P.S. "Wharfedale." Mr. Nevin.
South Shields P.S. "Bromoil in Monochrome and Colours." H. S. Becke.
Tyneside P.S. "Panchromatic Photography." B. Redford.
Welfare C.C. Scottish Photographic Federation Portfolio.
Hackney P.S. "Composition." R. H. Lawton.
Birmingham Phot. Soc. R.P.S. 1920 Competition Slides.
Nelson P.S. "The Farne Islands and Bird Life." G. A. Booth.
Stalybridge P.S. Lecture. J. G. Kitchen, of Messrs. Thornton, Pickard, Ltd

WEDNESDAY, JANUARY 25.

Borough Polytechnic P.S. Third Lantern Slide Competition.

FRIDAY, JANUARY 27.

Wombwell P.S. "With Allenby through Palestine with a Watch-pocket Carbine." Butcher and Sons.

SATURDAY, JANUARY 28.

South Suburban P.S. Annual Affiliation Dinner.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 17, Mr. E. W. Mellor in the chair.

A paper, entitled "Automatic Methods of Cinematograph Film Development and Fixing," was read by Mr. H. V. Lawley.

The author referred to the primitive methods still largely in use for the mechanical handling, in development, fixing and washing, of the very great lengths of film which were required in the trade circulation of a long drama film. One such film measured nearly a mile, and thirty duplicates were commonly issued to the theatres. Among the many inherent disadvantages of the system of development of short lengths on frames, was the continual variation in the strength of the developer. Mr. Lawley had designed, made, and had in regular working for over two-and-a-half years, a plant in which film is continuously developed, fixed, dyed, washed, and dried. Unlike others, it allowed of the period of development being adjusted without curtailing the length of treatment at other stages of the process. The plant consisted of a series of 2½-inch vertical tubes, most of them 26 ft. in length, through which the film passed, in festoons down and up each in succession.

The first two contained developer continuously supplied by drip feed from overhead tanks. On emergence from the first tube, after two minutes, the film could be given longer development, length by length, as seen to be necessary.

Owing to the very slight pull on the film, breakages of joins scarcely ever occured, and wastage of film was reduced to an insignificant fraction of 1 per cent. The floor space required for the whole plant was less than for the drying drums on the ordinary system, and a staff of three was sufficient for the management of three machines, each treating 1,500 ft. per hour.

Another feature of the system was the beautifully clean and polished condition of the film obtained by a species of vacuum cleaning before washing.

Mr. Lawley showed drawings of the plant and answered some questions; and on the proposition of the chairman, a most hearty vote of thanks was accorded to him.

CROYDON CAMERA CLUB.

Messrs. Vivian Jobling and E. A. Salt gave a joint lecture-demonstration on "Some Factors Concerning the Rapidity of a Lens," intended primarily for beginners. The system of marking stops was explained, and other factors dealing with rapidity, apart from aperture, were dealt with in simple language. A practical contrivance for directly reading the effective aperture was shown, and the lecture concluded with an exposition of a modification of Clay's pinhole and mirror method of measuring focal length. The model operated proved to be convenient and accurate in use. In the absence of drawings a reference to these devices, and the paper read, must be deferred.

In the discussion, Mr. Tayler narrated the experience of a friend, who complained to an assistant at a photographic dealers that the top speed, marked "1/1,000" of a focal-plane shutter purchased there, had on test showed a maximum speed of only 1/400th second, which was not fast enough for the work in hand. "Well if 1/400th of a second is not fast enough for you, the obvious remedy is to stop the lens down," suggested the assistant, whose ideas on the subject seemed a trifle mixed.

Referring to rapidity apart from aperture, Mr. Tayler said he had been the possessor of three f/4.5 anastigmats of recognised make, and had found one lens to be appreciably faster than the two others. He had also an enlarging lantern fitted with a rapid portrait objective. In practice this required stopping down to f/8 to obtain sufficient covering power, and then colour bands formed impossible to eliminate. He inquired why enlarging lanterns were so often supplied with these lenses. "Undoubtedly because they are the very worst for the purpose," volunteered Mr. Hibbert. For much the same reason all modern anastigmats were made without lens-hoods, because they most needed them, he added.

Mr. Harpur said he aspired to knowing nothing about optics, and much about lens-hoods. If really efficient ones were fitted there would be trouble when a thoughtless operator employed the rising front.

Working with a Goerz "Dagor," Mr. Walker had experienced more general fog on the plate when using a lens-hood than without one. It was, he said, inexplicable how some unhooded lenses with a very large circle of illumination induced but little general fog, whilst with others the reverse was the case.

Mr. Catharine said he had watched the action of his lenses very carefully, but had never seen them behaving in any way resembling the remarkable performances illustrated on the blackboard that evening. He had often been struck with the clear cut shadows and quality in the pictures taken with a single combination of the Zeiss "Protar."

Mr. Budd said he had been much interested in the recent articles in the "B.J" on the rapidity of lenses. Starting in the simplest possible way Mr. Geo. E. Brown gradually led the unsuspecting general reader into complex ground he would never dream of entering of his own free will. The simple explanation of the "H. and D. Doctrine" by the same author was another case in point. To understand the latter portion, he (Mr. Budd) had been compelled to study the original papers of Messrs. Hurter and Driffield. [An excellent result.—Eds., "B.J."]

On the proposition of the chairman, Mr. F. C. Reynolds, a hearty vote of thanks was accorded the lecturers.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held Monday, January 9. Present:—Messrs. J. Campbell Harper, George Balmain, Norman Thomson, E. D. Young, John Thomson, Laing, Fergusson, W. J. Hutcheson, W. B. Hislop, and A. Swan Watson. Mr. J. Campbell Harper, the president, in the chair.

The secretary read the report on the annual dinner, held on December 5, 1921, which was approved.

The meeting discussed the fixing of minimum prices for commercial photography. The secretary submitted the prices which were originally fixed and those which were afterwards substituted therefor, and also the proposed costing basis table, with a percentage of profit added, as proposed by Mr. Moffat. These prices were compared with those charged by similar associations, and were considered to be very reasonable. After considerable discussion, in which the views of the members were freely expressed and suggestions made, it was resolved to recommit the whole matter to the committee appointed at the meeting of March 7, 1921, of which Mr. Moffat was convener, for further consideration and report. Mr. Hislop was co-opted a member of the committee.

Messrs. James C. H. Balmain, A. Swan Watson, and J. Campbell Harper were appointed a committee to visit the classes at the College of Art, and also the class of Optics and Chemistry under the Edinburgh Education Authority, which classes are carried on under the able tuition of Mr. Drummond Young and Mr. W. B. Hislop, so that the interests of the Society in these classes might be maintained. The committee were requested to make any suggestions which, in their opinion, would improve the methods of tuition or otherwise in the carrying on of the classes. The secretary was directed to write to the Secretary of the College of Art, and also the Edinburgh Education Authority, informing them of the appointment of this committee, and to say that they hoped to visit the classes in the course of next month.

Arising out of Mr Robert Scott's suggestion that the time was most opportune for the formation of a northern federation to embrace the provincial towns, Mr. Young proposed that the Society should carefully and seriously consider the advisability of altering their constitution so as to admit of photographers from Aberdeen to Newcastle. It was felt that if there was such a federation, a Congress could be held in Edinburgh which would have the most beneficial effect on professional photographers, as so many of them are unable to attend the Congress of the Professional Photographers' Association in London. It was, however, pointed out that the constitution of the Society could only be altered at an annual general meeting, and the matter was in the meantime left with the members

to turn over in their own minds the best course which should be pursued.

It was agreed to hold an informal meeting of the Society at the Victory Café on Monday, January 23, at 8 p.m.

Commercial & Legal Intelligence.

NEW COMPANIES.

BOOTH GRIFFIN PHOTOGRAPHIC SERVICE LTD.—This private company was registered on January 2, with a capital of £1,500 in £1 shares (1,200 participating preferred and 300 ordinary). Objects: To carry on the business of photographers (commercial and trade), photographic and portraitive artists, advertising contractors, dealers in works of art, etc. The first directors are: H. Wm. S. Booth, Penn Manor, Wolverhampton; P. A. Court, 346, Soho Road, Handsworth, Birmingham. Qualification: 50 shares. Remuneration as fixed by the company. Registered office: 346, Soho Road, Handsworth, Birmingham

News and Notes.

DEATH OF MR. W. H. SIMMONS.—We regret to announce the death of Mr. W. H. Simmons, late of Kosmos, Ltd., Letchworth, Herts., on January 17, 1922, after a very serious operation.

LARES-MASTER PROJECTION PRINTER.—A descriptive circular of this vertical apparatus for printing, copying and enlarging reaches us from the Atlantic Photo Supply Co., 319N, Howard Street, Baltimore, U.S.A., by whom it is supplied, without lamp or lens, at 407.50 dollars.

OFFICIAL PRESS PHOTOGRAPHS IN FRANCE.—The Press Bureau of the French Foreign Office is now placing its photographs of events all over France at the disposal of journalists for the illustration of articles. These facilities are generously extended to English and American correspondents.

EASTMAN PORTRAIT FILM.—Messrs. Kodak, Ltd., have just published a 60-page booklet containing appreciations and expressions of experience of Eastman portrait film by about 120 professional photographers, among whom are leaders in the West-End of London and proprietors of studios of very various grades in different parts of the country.

A NEW AUTOMATIC CAMERA.—Among the novelties at Selfridge's Industrial Exhibition last week was a machine which takes a photograph and delivers it in three minutes in return for a coin. The camera can take 250 portraits without any re-charging of chemicals. No negative is used, there is no hand operation, and only occasional attention is needed to keep the machine in order.

CITY OF LONDON AND CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—There will be an open class at the exhibition of this society to be held at the Cripplegate Institute, from March 14 to 16. The exhibition will be opened by the Lord Mayor of London, at 3 p.m., on March 14. Entry forms for the open class are obtainable on application to Mr. J. J. Butler, 7, Gresham Street, E.C.2. The latest date for the receipt of entries is March 6.

STOCKTAKING BARGAINS.—Messrs. Wallace Heaton, Ltd., 85, High Street, Sheffield, have just issued a 60-page list of cameras, lenses and photographic accessories, which they are including in a New Year stocktaking clearance sale, at specially attractive prices. Vest-pocket and other folding cameras are a prominent feature of the list, which includes reflex, folding focal plane and studio cameras, as well as lenses of many different types and makes. Goods are offered on a seven days' free trial.

INCOME TAXPAYERS' SOCIETY.—Everyone who has to pay income tax and has had any experience of some of the methods, or, perhaps, one should say want of method, of Inland Revenue officials, will applaud the formation of this society under the presidency of Lord Inchcape. The Society has been established for the protection of the interests of the 2,450,000 people who now contribute the nation's most prolific source of revenue, amounting, with super-tax, to approximately £400,000,000. The Society provides payers of income tax with a strong central organisation qualified to give disinterested advice, and affords them an opportunity of being heard effectively. The Society will take legal action in test cases of importance, and, as we see in the Press at the time of writing, is about to contest the legality of assessing super-tax on the gross income, that is to say, before deduction of income tax. In the present circumstances, when the excessive drains of taxation are pressing both individuals and companies most injuriously, and are promoting trade depression and unemployment, the influence of a large and powerful association of this class of the community can be most beneficial. The subscription to the Society has been fixed at the purely nominal sum of 5s. for individuals; £1 1s. for corporations and firms. Inquiries and communications should be addressed to the Secretary, Income Taxpayers' Society, Iddesleigh House, Caxton Street, London, S.W.1.

STAFF DANCE.—The staff and a few friends of the Manchester branch of Mr. N. S. Kay, photographer, held a most enjoyable dance at the Deansgate Arcade Café on Saturday last. All the cares and troubles of the reception room, printing room and finishing

room were put aside, and everyone came with the determination to enjoy themselves to the utmost. Dancing, music, a card party and last, but not least, a well-served supper brought a most enjoyable evening to a close as the clock chimed eleven.

£3,000 ALL-BRITISH COMPETITION.—The announcement is made on another page of this issue of an all-British competition for amateur photographers in which £3,000 will be awarded in prizes. The competition is promoted by the following firms: W. Butcher & Sons, Ltd., Elliott & Sons, Ltd., J. J. Griffin & Sons, Ltd., Houghtons, Ltd., Ilford, Ltd., T. Illingworth & Co., Ltd., Imperial Dry Plate Co., Ltd., Kosmos Photographics, Ltd., Leto Photo Materials, Ltd., and Wellington & Ward. The prizes are awarded for photographs taken with one or other of the following makes of camera: Cameo, Carbine, Ensign, Klimax, Klito, Mascot, Midg, Pressman and Sanderson. Negatives are to be taken on Barnet, Griffin, Ilford, Illingworth, Imperial, Leto, Novex or Wellington plates. The printing papers to be used for the prints or enlargements are: Barnet, Griffin, Ilford, Illingworth, Imperial, Kosmos, Seltona or Wellington. The competition will be held in two parts, one closing on June 30 and the second on November 30. As will be seen from the prospectus and entry form, obtainable from photographic dealers, the organisers have subdivided each competition into seven classes, so arranged that the users of cameras both large and small and also those whose experience in photography is of the smallest will have favourable opportunities of winning a prize. All communications relating to the competition should be addressed to the office, at 4, Oxford Street, London, W.1, of the committee of management.

A NEWSPAPER PRINTED BY A PHOTO-OFFSET PROCESS.—The issue of the "Blackpool Times" for January 6, 1922, marks a new stage in newspaper production. The complete paper, both type and illustrations, has been printed on a rotary offset machine, and the plates prepared by a photo-lithographic process. The type pages

have been set and made up in the usual way, photographed by the wet collodion process, and then printed direct on to the zinc or aluminium plates for the machines. The illustrations are done by a high-light half-tone process. The type matter is remarkably clear and sharp, and the solids possess a strength which is never seen, and, in fact, cannot be obtained by ordinary rotary newspaper methods. The excellence of the result is more remarkable because ordinary newsprint has been used. The illustrations are interesting, since ordinary news photographs, including some taken by flashlight, have been used to produce results which are better than any newspaper prints we have seen, excepting a few in machine gravure, which are always printed on a much superior paper. The "Blackpool Times" is a bi-weekly paper of twelve and sometimes sixteen pages, and the photo-offset results since the first issue show an even better quality than the first one. The printers, Messrs. J. Robertson & Co., Ltd., of St. Annes-on-the-Sea, are to be congratulated on the enterprise shown in attaining success in this new field of newspaper production. We do not anticipate that the methods employed would be suitable for a big daily paper, in the present state of development, but it is evident that the new process has great possibilities.

Correspondence.

*** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** We do not undertake responsibility for the opinions expressed by our correspondents.*

THE PERSULPHATE REDUCER.

To the Editors.

Gentlemen,—In your issue of December 9, p. 726, referring to a recent paper on persulphate reduction by the writer, you state—"A year or two ago ("B.J.," July 12, 1918, pp. 314-315) Dr Sheppard, in a short paper, ascribed the *activity* of the persulphate reducer to the presence of minute traces of iron salts." This statement is not quite correct. My original statement was "B.J.," loc. cit. p. 314): "The small amount of iron salt present as an impurity in ammonium persulphate is thus the cause of its *variability*, and iron, however introduced, is a powerful catalyser of the action of persulphate on metallic silver." The recent investigations show that this should be qualified by reference to the acidity. It happens that most commercial samples which have come under the writer's observations have been but slightly acid, and their initial activity has varied according to the iron content. The levelling effect of relatively large amounts of acid appears to be due less to any counter-balancing of the action of impurities than to its direct part in the reaction, by dissolving oxide films.

As you state, the practical conclusion from this last investigation is that the reducer should be acidified with sulphuric acid to about ½ per cent.; the conclusions on the theory of the process, however, are somewhat contrary to your last pronouncement on that subject ("B.J.," March 11, 1921, p. 135), since no evidence for a "characteristic depth reduction" was obtained.—Yours faithfully,

S. E. Sheppard.

Eastman Kodak Co., Rochester, N.Y. December 28, 1921

THE P.P.A. CONGRESS.

To the Editors.

Gentlemen,—The suggested alteration of the date for holding the above is essentially a matter for discussion.

Before coming to a decision the Council should have ascertained the views and wishes of the members, and, if not too late, I hope they will take this suggestion in the spirit in which it is offered, and, if possible, act upon it.

A postcard referendum would be a simple, effective and inexpensive means of knowing how far the Council is supported in moving forward to September the annual congress and reunion. A reply-paid postcard or circular should be sent to every member, asking them to approve one of these dates, viz.: Do you approve of the conference still being held in April? Signature.

2. Or in September, as the Council suggest? Signature.

Provincial and country members do not get many opportunities of contact with the Council, so before coming to a decision in a matter so vitally important to the interests of the Association the executive ought to know the mind of the members and how far this new move is likely to be supported.

Personally, I favour the old date, with the added interest and attraction of the Photographic Fair.

I feel sure that April is the month when provincial and seaside members can be spared from their businesses much more easily and in larger numbers than in September!

In a matter of this kind affecting us all the *majority vote should decide*, and "the ayes have it!"—Faithfully yours,

S. H. Greenway.

27, Abingdon Street, Northampton. January 16.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. H.—The F No. of a telephoto lens is measured in the same manner as that of a positive lens, namely, by dividing the actual equivalent focal length by the effective diameter of the largest stop. The effective diameter is obtained by the well-known pinhole method in the same way as that of a positive lens.

W. A.—(1) A half-plate or whole-plate camera of square or broad taper pattern with R.R. lens of 7 or 8 inches respectively. (2) Exactly, so far as perspective is concerned it makes no difference what the focal length of the lens is. The focal length simply determines the scale on which the photograph is produced as seen from a given standpoint.

A. B.—(1) You can obtain gelatine sheets of various thicknesses from Messrs. Penrose & Co., 109, Farringdon Road, London, E.C.1. (2) Exposure is not materially affected. (3) As a rule a dark distemper background kept more or less in shadow, is used, but a dark green or brown serge will answer very well. It is very difficult to get a clear glass background in the negative; even black velvet will not give this unless well shaded.

L. G. B.—We think it would be quite practicable to close up the bottom of the sewer pipe with concrete, that is a mixture of about half and half fine sand and Portland cement. The paraffin is melted paraffin wax obtainable from any drysalter. Probus paint is a waterproof and acid-proof paint on the market in America, but not here so far as we know. A substitute suitable for the purpose is the anti-sulphuric paint sold by dealers in electrical requisites as an acid proof coating.

F. Richards.—We think the best thing you can do is first to clean the print by making some ordinary flour paste and brushing this over with a soft brush so as to brush away dust or dirt in the crevices of the paper. Then, after rinsing the paste off under the tap, soak the print in glycerine and squeegee to a glass plate and photograph through the glass. If the print is on a thin paper it would be well to apply a sheet of white paper behind it when photographing. We think if you do this you will get the least amount of grain showing in the copy. Exposure should be full so that detail begins to develop up readily.

R. B. W.—The reproduction appears to be made from an original which has been entirely worked up by hand. The effect could be got by giving a thin coat of white all over the subject by means of the spray apparatus and then working up with black where necessary. Or the dark parts may have been painted all over

with "Masklene," a preparation sold by the Aerograph Co., the white sprayed all over and the "Masklene" dissolved off. If you write to the Aerograph Co., 43, Holborn Viaduct, London, E.C.1, they will send you particulars. As a rule special artists are employed by the block makers to do this class of work.

T S. M.—The camera is not at all a suitable one for use from an aeroplane. It is rather inconvenient to handle and, dependent upon the amount of vibration of the machine, it is very doubtful if 1/90th of a second nominal speed of the shutter will be sufficient to obtain sharp negatives, even if focus is sharp. Most aerial photographs are taken with a focal-plane shutter, as much on account of the vibrations of the machine as on account of the movement of the image due to the movement of the aeroplane. Apart from one of the special aerial cameras, about the best for the purpose is the ordinary focal plane, such as is used by Press photographers.

G. C. R.—We cannot give you a formula for making a more transparent medium than those already on the market, none of which is in the slightest degree opaque. The fact that the medium is visible in enlarging is due to the fact that it refracts the direct rays of light slightly, but this can be overcome by placing a ground glass between the light and the condenser. It is a good plan to rub the medium *all over* the negative, then the edges will not show. In many districts the washing water deposits a fine film of lime all over the negative and the medium renders this transparent where it is applied. The remedy is to swab the negative thoroughly with a pad of cotton wool before placing it in the drying rack. Possibly you have been putting on the medium too thick; if so, ridges are often visible in the enlarged image.

R R.—The under-exposure of the flashlight exposure is evidently due partly to the small stop in the lens and partly to the use of a not sufficiently rapid plate. Perhaps also partly to the powder not being spread out into a long enough train. You should be able to get sufficient definition with *f*/16 stop or at the outside *f*/22. You should use one of the ultra-rapid Iso plates, such as the Marion "Iso Record" or the Barnet "Super Speed Iso." Also the powder should be spread out to a length of from 1 to 2 ft. at least. If the lamp is not long enough for this, a strip of sheet iron bent into shallow trough form will answer, the powder being fired by means of a small piece of guncotton placed about midway along the train of powder and ignited by a match held on a stick of 2 or 3 ft. in length. As regards focussing, the lights in the hall ought to be of sufficient power to allow satisfactory focus being obtained, particularly if you use a magnifier.

E. J. C.—(1) We suppose that the photographer named pays a certain sum for the sole right to take photographs of any description on the pier. He therefore is within his rights in preventing any person from using a camera on any part of the structure of the pier. (2) On the other hand, if a person manages to take any snapshots on or from the pier no action could be taken against him under copyright law, and we do not think that any action at all could be taken. (3) Rights in the foreshore of a seaside place are usually regarded as the property of the local authority, which therefore has the power to prevent anyone from taking photographs or offering photographic work on this place. Certainly the local authority would take this course if it has granted a licence to some one photographer for a given period (4) We do not think it would make any difference, as regards restriction of photographic work on the foreshore, whether another photographer had a business in the town and an order from his customer on the foreshore.

H. R.—The following is the best formula we know for oak stain for frames:—The materials are Vandyke brown crystals and washing soda. The former are not sold by every drysalter, though obtainable at the larger colour stores, but can be had from firms such as Messrs. Cashmore, Victoria Street, Bristol. The powder Vandyke brown is not suitable, as it clogs the grain of the wood and destroys the pattern. To make the stain, mix 2 to 3 ozs. of Vandyke brown crystals with a handful of washing soda. Place in a saucepan, with half gallon of water, bring to the boil and continue boiling until thoroughly dissolved. The mixture is then bottled for use. It can be mixed with further water according to the depth of colour required. If applied hot it sinks more deeply into the wood, though it is quite efficient when used cold. The stain should be well rubbed into the wood with a short bristle brush. If desired, the stained frame, when dry, can be well rubbed over with a little linseed oil, which gives a semi-polish and imparts a lustre to the colour.

H. P.—For heavy pyro stain the most effective remover is the bleach of permanganate, salt and acetic acid, introduced some years ago by the Ilford Co., followed by re-development. We give instructions from an article in a past "Almanac":—

Potassium permanganate	50 grs.	517 gms.
Common salt	¼ oz.	12.5 gms.
Acetic acid (glacial)	1 oz.	50 gms.
Water	20 ozs.	1,000 c.c.s.

If the negative is one freshly made, it is as well to pass it through a weak bath of chrome alum (about 50 grs. in 10 ozs. of water, *i.e.*, 10 gms. per litre) before applying the bleacher. The latter is allowed to act for 10 minutes, rocking all the time. It cannot harm the gradations of the negative, and this full time makes sure of the removal of the stain, and avoids a repetition of the process. After a brief rinse the negative is left in a solution of potass metabisulphite (1 oz. in 20 ozs. of water) until white everywhere to the back of the film, and is then re-developed in any non-staining developer. This formula will remove the heaviest stain. In less obstinate cases stain can be removed by soaking the negative in hypochlorite solution, very conveniently 1 oz. of the "Milton" sold by chemists mixed with, say, 10 ozs. of water, or less if necessary.

G. G. (Winnipeg).—The following are particulars of the Playertype process. You will see that it depends on the difference in the reflecting power of paper caused by the presence on parts thereof of any black impression, a photographic silver image or an ink impression. The engraving (line drawing) to be copied is laid face downwards upon a perfectly flat surface, the sensitive (bromide) paper is laid film side downwards upon it, and a sheet of glass placed over all. A yellowish light is then held over the glass, the exposure being made through the glass and the sensitive paper. From three to ten minutes may be necessary in yellow light, according to the sensitiveness of the paper; with white light the exposure is much shorter. The developer recommended for this work is:—

Hydroquinone	30 grs.	7 gms.
Sodium sulphite	120 ,,	28 ,,
Sodium carbonate	240 ,,	56 ,,
Water	10 ozs.	1,000 c.c.s.

Development is continued until the image appears to be buried. Having obtained a negative in this way, prints may be obtained from it by contact printing. The method has the advantage of giving a direct copy (a paper negative) of the same size as the original, and, of course, without using a camera. The clearer and more contrasty the original drawing or engraving, the better will be the copy on the bromide paper, but should the latter be faulty, it may be intensified, reduced, or cleared. The process was modified somewhat in 1900, when a sheet of green glass was laid over the paper, and the exposure, of from five to ten minutes, made through that. The process has recently been revived in a somewhat different form as the "Manul" process, recently patented in Germany by Ullmann.

IMPORTANT NOTICE TO READERS.—Until further notice agents will supply the "B. J." to order only, as the high price prevailing for everything in connection with newspaper production prohibits the distribution of surplus copies for chance sales. It is therefore necessary in order to ensure the regular delivery of the "B. J." to place an order definitely with a dealer, newsagent or bookstall clerk, or to send a subscription to the publishers.

HENRY GREENWOOD & Co., LTD., Proprietors and Publishers, 24, Wellington Street, London, W.C.2.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3221. Vol. LXIX. FRIDAY, JANUARY 27, 1922. Price Fourpence.

Contents.

SUMMARY.

At the Royal Photographic Society last week, in connection with the exhibition of his portraits of "Men of Mark," Mr. Walter Stoneman delivered an interesting and humorous address recounting his experiences of sitters, famous, fair and funny. (P. 47.)

Almost the final stages in the incorporation of the Professional Photographers' Association were taken at a recent meeting of the council. (P. 55.)

We refer on page 45 to a little point of etiquette which surely should be strictly observed by photographers who wish to be regarded as "professional."

Those with a little mechanical aptitude and a modicum of skill in the use of size or oil colours, can readily make their own backgrounds. In an article on this subject we refer to other methods of preparing backgrounds and of introducing variations into them. (P. 46.)

The principles and practice of stereoscopic photography of small objects are the subject of a paper by the Rev. H. C. Browne, in which the optical and visual conditions which require to be observed in obtaining correct stereoscopic reproductions are considered in detail. (P. 50.)

The offset method of printing, which has been adopted by a northern newspaper, foreshadows revolutions yet to come in newspaper production. (P. 46.)

A photographic method, but one eliminating the use of a camera, is being employed in Germany for the production of re-editions of books, the type of which has been distributed. (P. 46.)

Some practical precautions in the use of the method of toning in which the bleached print is first treated in a diluted developer and then in sulphide, are recommended by the Eastman Research Laboratory. (P. 45.)

One or two hints for those beginning the practice of carbon printing will be found in a paragraph on page 45.

The photography of reflecting objects, making of cheap enlargements, measurement of effective diameter of a lens stop and methods of photographing shop fronts are among the subjects of brief replies to correspondents. (P. 60.)

The Bournemouth Camera Club has now its own permanent premises and work-rooms in the municipal building. (P. 49.)

An official service has been established in Italy for the supply of photographs of events, etc., in that country. (P. 57.)

A correspondent refers to the first text-book of bromide printing, written by Mr. J. Burgess for the firm of Morgan, afterwards Morgan and Kidd of Richmond. The date of publication, namely, 1880, establishes that of the commercial manufacture of bromide paper. (P. 59.)

The construction of an automatic printing and enlarging machine, in which a continuous band of sensitive paper is exposed, is the subject of a recent patent specification. (P. 52.)

EX CATHEDRA.

Sulphide-cum-Developer Toning.

It will be remembered that a useful variation of the sulphide toning process originated a year or two ago by the Kodak Company in this country consists in treating the bleached print with a dilute developer sufficiently to bring up the image of faint purplish tinge, then sulphiding in the usual way. This method of mixed toning has recently been the subject of a report by the Eastman Laboratory in Rochester, as the result of tests made with it on Artura and Velox prints. As a result, it is recommended that the artificial illumination of the room in which prints are handled up to the stage of taking them out of the developer should be kept constant. While any ordinary developer may be used, provided that it is sufficiently diluted and used only for one batch of prints, a formula that is specially recommended is one containing only 1 per cent. of hydroquinone, 1 per cent. of anhydrous soda sulphite and 4 per cent. of borax. Obviously, in order to secure an even tone throughout a batch of prints, it is of special importance to stop the redevelopment of the bleached prints at the right point. The Eastman Laboratory finds that preliminary trials are essential in order to find the best degree of development. The time and temperature should be noted for a particular emulsion and negative, and these data adhered to in the subsequent use of the same developing formula. If this is done it is quite practicable to duplicate on any subsequent occasion the excellent tone which the process yields.

* * *

A Point of Etiquette.

We heard the other day of a little incident of a kind which ought not to happen if photographers observed in practice the claims which they make for their occupation as a profession. A customer had made an appointment for a sitting at studio X at a certain time. By inadvertence he made his way into studio Y, situated a few doors away. Announcing that he had come to keep the appointment, he was received as a matter of course, and the portraits duly made. It was not until afterwards that he discovered his mistake. We are not concerned with the business dispute between the two photographers, or with the question whether the sitter has or has not given an order to studio Y nor with the question whether studio Y has any rights of reproduction in the photographs made in the circumstances we have mentioned. But it is desirable to emphasise that portrait photographers, if they wish the public to recognise them as professional men, should observe a code of etiquette which certainly should render impossible the surreptitious taking of an order which belongs to another studio. It ought to be obvious to anyone who snatches an order which comes his way through such an error on the part of a sitter, that he does harm not only to himself but to the status of professional photographers generally. The customer is not

likely to think very much of him, and, reasoning from the particular to the general, is inclined to put down photographers in the mass as little men who are not above taking an underhand advantage of each other.

* * *

Tyros in Carbon. Not the least of the merits of the flexible negative film is its adaptability for carbon printing by the single transfer process. When the carbon print is developed direct upon its permanent support its production is little more difficult than that of a toned bromide print, and given a negative of good average quality the results are vastly superior in appearance. There is no uncertainty as to colour, and there is a large range in surface and colour of the final support. There are a few points which should be noted by those who have not yet tried carbon printing. One of the most important is that a contrasty negative is not necessary nor even desirable, although a hard negative will give a better result in carbon than in any other medium. Another, is that the beginner should use only ready-sensitised tissue, so that he is not handicapped by drying troubles at the outset. A third, is that over-printing which necessitates the use of very hot water in development should be avoided. Obtaining correct exposure is not easy at first, and the beginner should use as well as the tint actinometer, a pilot negative, equal in density to that being printed from. A small piece of P.O.P. printed to a light proof depth will take about the same time as fresh carbon tissue.

* * *

Photography and the Printing Press. Perhaps those who read our short paragraph last week on the photographic method employed for the production of a weekly newspaper, "The Blackpool Times," may not have sufficiently appreciated the developments in printing which it foreshadows. Briefly, the process consists in setting up the letterpress in type, photographing the latter on wet collodion, and from the negative printing on to sensitised zinc or aluminium. The inked-up impression on these plates, as also that on similar plates prepared from the photographic illustrations, is transferred to the actual printing surface and the offset impression thus applied to the paper. Apart from the advantages which we mentioned last week, no doubt one of the first things which will occur to the technically-minded reader is that the process of setting up letterpress in metal type and taking a proof of it is a costly method of providing an original for the camera. Nevertheless, at the present stage in printing houses it represents the readiest procedure which can be followed. But, as has been suggested not so very long ago, inventors are at work on the problem of eliminating the type-setting part of the process altogether and of providing, by mechanical means, a system which can produce more cheaply the required original which is to be photographically copied. The problem is surrounded with innumerable difficulties, as any printer realises; and we do not suppose that type-founders or printers' compositors are yet quaking in their shoes for fear that their occupation is to be taken from them by a photographic process for the production of an original for the offset printing machine. Nevertheless, the future will almost certainly witness great developments on these lines.

* * *

Photo-Copied Books, Apropos the part which photographic methods are playing in letterpress printing, an example recently came under our observation of the commercial use in the production of books of a photographic process which we described a few months ago, namely, the Manul process which has been developed in Germany by Max Ullmann. Manul, as we pointed out in our issue of October 28 last, is a variation of the old Player-type process, permitting of photographic copies being made by contact printing from letterpress which is printed on both sides of the paper. In place of a bromide or gaslight paper, as in the Player-type process, Herr Ullmann uses a film of bichromated albumen. We did not know, however, that the process was finding commercial application until the other day, when we received a re-edition of a technological dictionary issued originally by a Munich firm in 1910. The later (1921) edition is described on the title page as produced by the Manul process; that is to say, the printed pages of the original edition have been photographically reproduced without the use of a camera, and by this means the extremely heavy costs of re-setting again in type or, alternatively, photographing with a lens have been eliminated. The sharp impression throughout 1,322 pages of closely-printed letterpress, containing also many hundreds of fine drawings, is as good as could be wished, and affords an illustration of the great value of the process for the production of facsimile reprints of books, the type of which has been distributed.

HOME-MADE BACKGROUNDS.

Now that the scenic background has almost passed into the limbo of forgotten things, it should not be a difficult matter for the photographer to provide himself with a selection of useful and presentable backgrounds for a very small outlay on materials, the work being his own in spare hours. It is now generally agreed that it is most convenient for each background to be stretched upon a frame which is supported by feet which may run upon castors or, what is cheaper, the largest size of the polished knobs known as "domes of silence," which may be obtained of any ironmonger. If it be decided to make one's own frames, rough battens, three inches by one, will be strong enough. The corners may be morticed or "halved," and at each angle a brace about a foot long should be fixed flush with the general surface, these being cut from the same sized battens. The feet should be triangular, about fifteen inches wide at the base and ten inches high, and should not be fixed until the background has been stretched and painted.

For most work, eight feet by six feet is a convenient size, as this is wide enough for one or two figures, and is much easier to handle than the usual standard of eight feet each way. The most convenient material is strong unbleached sheeting, which may be obtained in various widths up to three yards. It should be turned over the edges of the frame and secured upon the one-inch side of the wood with tinned tacks, starting in the centre of each side and working to the corners so as to avoid creases. This can most conveniently be done with the frame lying upon the floor. Both sides of the frame should be covered with the calico. The next step is to give a sizing of starch made as for mounting, but rather thinner, the object being to prevent the distemper colour from being absorbed too readily by the material.

Ordinary size colour may be used for the final coating, but it will generally be found more convenient to purchase one of the ready-made mixtures which only require the addition of water. The colour should be applied sparingly with a flat brush, two thin coats giving a more even surface than one thicker layer. It is rather difficult to make a really black distemper; what is sold under that name dries a dark grey. This is greatly improved for photographic work by adding a certain proportion of dry Venetian red, from the oilshop, to the dry powder, mixing

it well before adding the water. It should be noted that distemper colour is much lighter when dry than when wet, so that it is necessary to coat a piece of brown paper with the mixture and to dry it at the fire before starting on the calico.

If it be desired to graduate the background or to work in a cloud effect the colour should be made with size and about three shades mixed separately, these being blended upon a large square of wood and worked into each other on the canvas. For this class of work the distemper should be kept until it smells rather disagreeably, when it will be found to work much more smoothly.

Oil colour may also be used upon the starch substratum and is much easier to work for cloud effects, as no allowance has to be made for drying. The ordinary tinned paints answer well if they are allowed to stand for a few days and the supernatant oil poured off, the colour being thinned down with turpentine only. This prevents gloss when dry.

A clean and easy way of making a background is to use the wide "art" serges which can now be obtained fairly cheaply. They are usually about fifty-four inches wide, so that a join may be necessary. If machined stitched and the seam pressed the join will not be visible upon the negative. Dark green and red for dark backgrounds and blue for a lighter tone are the best colours to select. A really black background which will give practically clear glass upon the plate is rather difficult to obtain, and so far nothing has been found to equal black velveteen. Even this reflects some light and it is liable to look rather patchy, unless it is kept well in shadow. In some studios it has been found necessary to add black side and top curtains, so that the sitter is in front of what is practically a black-lined box. Fortunately, this intense blackness is rarely wanted, the ordinary materials being dark enough with just a suggestion of atmosphere. Serge backgrounds have a very useful way of lending themselves to temporary modification, a little french chalk being dusted on to relieve the figure where necessary. When no longer needed the chalk is easily removed with a clothes brush. It is rather important to use french chalk or talc, as ordinary chalk or whitening cannot be removed so easily. An even more evanescent method of obtaining a graduated background was introduced by M. Adam Salomon. It consisted merely of moving a white card up and down behind the sitter during a part of the exposure; although it necessitates the presence of an assistant, this simple dodge is worth remembering.

A pleasant variety may be introduced by using a draped background which is easily done by fixing a curtain pole and brackets at the top of a background frame. When needed, a plushette or serge curtain may be affixed to this and used either in straight folds or looped up as fancy may dictate. Very bold patterns in serges and cretonnes may be used with good effect.

The number of tones available may be greatly increased by judicious placing of the ground. Taking one position as normal, it will be found that a lighter shade is obtained by turning the surface towards the light, and a darker one by turning it away. Anyone who has not observed this will be surprised to find how, when the shadow side of the face merges into the background, it may be made to appear in relief, either darker or lighter than the ground by this simple device. It is here that the full value of the movable background frame is seen to advantage.

It is hardly necessary to point out that the end walls of the studio should be finished, so that they will serve as backgrounds for large groups. This may be done by artistic paper-hanging, or by fitting oak panelling or one of the imitations such as Linerusta or Anaglypta.

FACES IN THE STUDIO.

Mr. Walter Stoneman, whose "Men of Mark" have attracted much attention at the Royal Photographic Society, gave a lecture in the Society's house on January 18 on "Faces, Famous, Fair, and Funny." The chair was taken by Mr Furley Lewis, who got a special dispensation from his doctor in order that he might be present to extend a welcome to a brother portraitist. Many illustrious victims, he said, had fallen to Mr. Stoneman, who no doubt felt as he did that one came just about as near to human nature in studio portraiture as one could do anywhere.

Mr. Stoneman, in opening his lecture, said that the photographic studio was one of the most interesting places in the world. There one could really and truly see life—men, women, children and dogs. He began with a doggy story. Some years ago a very distinguished lady came to the studio accompanied by a huge boarhound. Somehow the dog could not be induced to take a natural pose. He himself at that time was doing the focussing, while the operator was attending to the posing. With his head under the cloth, he made a low growl, with the object of inducing the animal to look more intelligent, whereupon the boarhound sprang, not at him but at the poor operator. The operator was a brave man, and stood perfectly still, so that the animal leapt beyond him but he said that if that incident was going to be made again he would prefer to be behind the camera.

But to return to faces. Every face was absolutely different. No two faces in the world were alike. He had photographed 25,000 people in the last twenty-five years, and he had never seen any face which was a perfect likeness of another. Sometimes, however, the resemblance was very close. Recently two brothers visited his studio, and when he saw them he glanced from one to the other and could not imagine why there were two. He told the operator to be sure not to photograph one of them twice by mistake, and actually after he had photographed one brother he had to ask him kindly to leave the studio so that he might be sure that he was photographing the other. When it came to the negatives there was no discoverable difference in the faces; only the clothing indicated which was which.

The face, of course, was only one medium of expression. What attracted us in our friends was perhaps rarely their faces, but more generally their voice, their manner, their character, and the less superficial side of personality was not easily conveyed through the camera. That was no fault of the operator—horrible word, enough to prejudice the whole business to start with—nor was it any fault of technique; it was simply that the human face, especially in rigid repose, expressed so little. Hence the expression "I never make a good photograph," which paralysed the creative faculties of the photographer at the very commencement. If the photographer was quite candid he would say to some people, "And you never will," and if he was ultra-honest and had not got a wife and family to support he would add, "It is on account of your face." That did not mean that the personality was uninteresting. Under the stimulus of enthusiasm the plainest face became transfigured and were no longer

a mask. And as for the people whose features made good photographs—well, he would not care to live with some of them.

All this was specially true of women. The personality of women was elusive. A certain charm about them, like a musical voice, was unphotographable, though, apart from the features, there were certain things which helped the photographer, such as the figure and the dress. Often in the old days had he sighed for the opportunity of photographing women in colour, and, of course, this was now possible. He wondered why his brother photographers did not make more use of the Autochrome. It was perhaps not very profitable, but it was wonderfully interesting. In men the figure and the dress were of minor importance; though, of course, a uniform or a smart suit were sometimes valuable—they took one off the face! In this connection he referred to the wonderful article by Mr. Pirie Macdonald in that week's "British Journal of Photography." It was very American, though none the worse for that, and very attractive. He called it "The Trick of Taking Men," and personally he already owed Mr. Macdonald quite a great deal for the stimulus of that article.

The Famous.

In describing some of his famous sitters, confining himself to those he had personally taken, Mr. Stoneman began with His Majesty. He first photographed him as Prince of Wales, and the Queen as Princess, fifteen or twenty years ago at Mount Edgcumbe, in Devon. The photograph was taken at half-past five in the afternoon, and, with what he thought in those days was great expedition, he had the proofs ready by ten o'clock the same night, and was wandering about the dark quay looking for a boat to ferry him across to where their Royal Highnesses were staying. He last saw the King at Sandringham, where he appeared like a happy country squire, and, meeting him in the road, King George asked him a few questions and wished him good luck. On one of his visits to Sandringham they sent a royal car to the station to meet him, and he got a number of salutes from passers-by in consequence, but on another occasion, when he was commanded to photograph the King of Norway there was some mistake as to which of the two little stations he should arrive at, and, getting out at the wrong one, he found no conveyance available, and had to walk three and a-half miles to the house, with the result that he was half an hour late, and the King, a stickler for punctuality, was perturbed, as he was himself. However, he got to work, and both King Haakon and Prince Olaf shook hands with him at the close. He had shared the honour of photographing the Prince of Wales with other London photographers and some thousands of his future subjects. The Duke of York and Prince Henry were both excellent sitters. On one of his visits to Buckingham Palace Princess Mary was present, and the Duke of York told her that Mr. Stoneman ought to photograph her, but she replied that he had already "done a very nice one of her," on horseback, at Sandringham.

Mr. Stoneman had a good deal to say about admirals, especially the late Marquis of Milford Haven, a very handsome and most kindly man. On one occasion, down at Devonport, he (Mr. Stoneman) was not merely given the privilege of photographing a launching platform, but was also given the delicate duty of choosing three other photographers to share the privilege. He found, however, in looking after his colleagues and competitors, that he had lost his own position, but a friendly admiral stopped him when he was going away with his camera in disappointment and took him to a much better perch, where he got such pictures of royalties as subsequently occupied full pages in the illustrated papers. There was a moment's perturbation, however, when the admiral in command, Prince Louis of Battenberg, as he was then, spied him in his close-up position, and the proceedings were nearly interrupted, but the admiral who had got him the place explained matters, and, with bows and smiles, the Prince allowed him to remain.

Other admirals who had given him sittings included Admirals Tyrwhitt, Keyes, and Reginald Hall. The last-named looked after the spies in the war, and when he sat in the studio he gave as an excuse for not assuming a more vivacious expression that his head was chockful of secrets. Perhaps the most characteristic of all these sea-dogs was Sir Charles Beresford. On the first occasion when he photographed him he had the camera all ready, because he had heard that he was a hasty subject, and Lord Charles walked down to the spot, buttoning his gloves, asking where it was desired that he should stand, and saying that he could only give one plate. The moment the exposure had been made he walked off, wishing the photographer success, a wish which the photographer echoed, although he doubted. But his lucky star was in the ascendant that day, and when, twenty years later, he photographed Lord Charles Beresford in the studio the admiral told him that he was still ordering that early photograph. Mr. Stoneman was struck with the modesty of naval and military figures, perhaps because one specially admired a virtue one did not oneself possess. Modesty was scarcely a photographer's characteristic. Lord French and Lord Haig did not appear to care for photography, but all five army commanders faced his camera during the war.

The best of all sitters was the present Prime Minister, whose picture dominated the photographs on the walls. A photographer had no politics, but he could not help saying that it was a statesman's face that looked out at one there. About sixteen years ago he photographed Mr. Lloyd George in a friend's garden. The garden was not very level, and the chair not very comfortable. Before exposing he said to Mr. Lloyd George, by way of suggestion, "A winning smile?" There was a General Election on at the time. "Steady," replied the future Premier, "let's get a safe seat first." At the close Mr. Lloyd George went up to the photographer, and said, "Who's going to win Devonport?" Mr. Stoneman robbed him of any illusions by telling him, "Not your lot." Speaking of Sir Eric Geddes, Mr. Stoneman got back among his favourite admirals. During the war he received a telephone message from the secretary to Sir Eric Geddes, telling him to come down and take a group. He went down, and at the back of the house in Queen Anne's Gate he found a group of all the Allied admirals—English, French, Italian, Japanese, and American (Sims)—and he himself the only photographer. Nobody knew that the admirals were in London, and he was not allowed to release that picture until twenty-four hours after they had gone away.

Among the peers one did not now find the type of aristocrat who flourished twenty-five years ago. Of all his sitters peers least looked the part, and on one or two occasions he had had to refer to his appointment book to make sure as to the identity of his sitter. Labour members had striking faces, and showed in many cases marks of their early toil. He remembered one of them whose face—and, as he told him, the upper part of whose body—was disfigured by a multitude of tiny black marks, the result of the impact of little pieces of coal while he was working in the mine with his pick. Time failed to tell of the bishops, who had visited the studio by the dozen. A photograph at Lambeth Palace, when 240 right reverends were present, was familiarly known as "yards of bishops." One of the bishops who was taken separately, thinking the photographer must be growing weary of the ecclesiastical face, said as he left the studio, "You must be tired of us blooming bishops." Free Church ministers were, as a rule, rather more approachable. Scientists had expressive faces, but were not particular about their clothes. It must not be imagined that it was only the ladies who were vain. Once he opened a dressing-room door, and found the gentleman who was about to be photographed gazing at himself in the mirror with his moustache in curling pins! An officer who came with his servant rapped out questions

between each exposure, "Is my hair straight? . . . My coat right? . . . My tie straight?" Authors were easier to photograph than authoresses. He asked Conan Doyle whether he did not feel particularly at home in Baker Street, and the creator of Sherlock Holmes said that he did. Mr. Burgin said that he spoke to a policeman in the street, "Can you give me 73, Baker Street?" and the policeman replied, "I am afraid I can't, sir, Russell's have got it." He anticipated a visit from W. W. Jacobs with much pleasure, but the author arrived with an air of gloom and resignation that would not have disgraced an undertaker. After exposing two plates, the photographer remarked that he thought the funeral was proceeding satisfactorily, but that he could have wished for a more lively corpse. Afterwards Mr. Jacobs told him one or two original stories, and he was able to get a more satisfactory picture.

Before leaving the famous for the fair, Mr. Stoneman spoke of how greatly men appealed to him as sitters. Why did men neglect the studio? He believed they had an idea that the photographer still used the head rest. At any rate they were sure that they could be photographed equally well walking about—an idea encouraged by press photographers. Some men told him that they had not been in a studio for twenty years, and said it as though it were praiseworthy on their part. The Professional Photographers' Association ought to engineer a Bill through Parliament to compel every man, woman and child to be photographed every three years at least. That would be very useful and good work for the Association. After all, a good photograph was a priceless thing. When we passed away our personality faded: there was only a memory left, but that memory was best revived by the photographic resemblance. The most precious thing to many people was a photograph of someone whom they had lost, and it was a man's duty to his children to leave them this heritage.

The Fair.

Among fair sitters he placed first of all Queen Mary. He counted it one of his greatest privileges to have spent a morning at Sandringham in her company, and to have photographed her on three occasions. Of Queen Alexandra's charm he did not need to speak. She once came out to be photographed with old Sir Dighton Probyn, and although he got a chair for her she made him sit down while she stood, and they were photographed together. Other royal ladies whom he had photographed were Princess Mary and Princess Arthur of Connaught, the latter as a nurse making a charming picture. Of the lady members of the House of Commons, Lady Astor was too vivacious in personality, too full of life and enthusiasm, to make a really good photograph. Mrs. Wintringham, M.P., belonged to an entirely different school; he was immensely impressed by her personality. He had not photographed Mrs. Asquith, and therefore could not expect to appear in her reminiscences. Authoresses were not good sitters, but they had afforded him some interesting hours in his studio. In the musical world he recalled photographing Madame Antoinette Sterling years ago, and from some fancied likeness to her son she took a fancy to him, and gave him much helpful counsel. In more recent days he had seen a good deal of Madame Clara Butt, whose husband, Mr. Kennerley Rumford, was a good amateur photographer, and if he did not make a mistake sometimes, such as in excessive economy, getting two pictures on one plate, he would ask him to join his directorate. He related an amusing story of how the Rumford family were photographed in the order of their stature. Madame Clara Butt, of course, was the tallest, but the father expected to be the second; his claims, however, were disputed by two of his children, and he was reduced to the fourth in rank!

Mr. Stoneman concluded this portion of his lecture with a reference to the children, the fairest of the fair, in the photography of whom he had revelled, and with whom he had sometimes played so long as to forget to make his record.

The Funny.

Without a sense of humour no one ought to be a photographer. Why, there was even a sense of humour in a convict prison. He recalled being present at a service at Dartmoor—he was there professionally, and not under duress!—when the organist played the "Wedding March" as the convicts went back to their places. He had been asked to say which of his portraits in the present exhibition was the funniest! If he answered such questions he would not be able to give any more free lectures, but would have to take collections to keep himself alive. All the laughter in the studio was not on the photographer's side. He had an old country couple up from Cornwall once, and the man started grinning. He took one photograph, thinking this was the natural expression, and then a second, and then he said, "Now, supposing we try a more serious picture." "Oh," said the man, "I can't help a-laughing, looking at you." There were plenty of humorous faces, but few comical ones. He used to think that Dickens exaggerated, but he believed that every character Dickens ever portrayed had passed in front of the camera these last twenty-five years. Occasionally a really funny sitter was encountered. One such was the late Sir Hiram Maxim, who was able to tell funny stories until he had thoroughly upset the gravity of the studio. Recently he had to photograph a very wealthy Jew, and found it difficult to get a characteristic picture. There was not the glamour about the face which one associated with money-making. Presently he said to his sitter, "I wonder if you could imagine yourself at your shareholders' meeting, announcing that the profits of the year ——." The Jew put his hands on the chair, assumed a well-satisfied expression, and ejaculated, "Millions." "Don't move," said Mr. Stoneman, who got a picture which was worth its weight in gold.

Sometimes men were ordered to the studio by their wives. One very distinguished diplomat years ago was brought to the studio by his wife, who left him sitting in the chair in front of the camera. Mr. Stoneman began to focus, while the sitter shifted uneasily, and before the work could be completed rose and said, "I suppose that's all, thank you very much" and trotted off down the stairs, Mr. Stoneman following. At the foot of the stairs he met his wife. He looked at her, he looked at Mr. Stoneman. He chose the lesser of two evils, and went back to the studio.

Mr. Stoneman concluded with a nice little exhortation to his audience to the effect that we were all responsible for the expression on our faces, that if we could not all be handsome we could all be good-looking, that the transient ugliness which came into our faces was of our own making, and that we had to beware lest the feeling which gave rise to a momentary expression of disagreeableness became habitual and so translated itself into the facial contour.

There was a very hearty vote of thanks.

Bournemouth Camera Club.—New headquarters have recently been obtained by this club on the lower ground floor of the Town Hall, where most convenient premises have been leased from the Corporation for the exclusive use of the club. They include a large club room, and developing and enlarging rooms, thoroughly equipped for practical work. The premises were officially opened last week by the Mayor, Alderman C. H. Cartwright, who expressed the pleasure he felt in supporting so admirable an educative enterprise. The new premises, which are available for the use of members every day from 10 a.m. to 10 p.m., will undoubtedly add immensely to the usefulness of the club, the annual subscription for which is only 10s. Particulars of lectures, demonstrations, and excursions may be obtained from the hon. sec., Mr. Francis G. Burroughs, 88, Old Christchurch Road, Bournemouth.

THE PRACTICAL STEREO PHOTOGRAPHY OF SMALL OBJECTS.

(*Continued from page* 36.)

The vertical space or frame thus marked out has a threefold function. It constitutes what will be called *object width*, which determines the whole width of the available space within which the object must be arranged. If the object is wider than this, only so much of it can appear in the stereo image as lies between the two verticals; if the object is to be taken as a whole, it should be considerably narrower than this, in order that it may be artistically displayed. For instance, in the first example about to be given, the *object width*, or distance between verticals is 7½ in. For effective display the actual object, or objects, should not be more than about 5 in. wide. There will then be sufficient room in which to arrange the group in a pleasing way. Artistry in stereo work is of quite as great importance as accuracy. The next function of the two verticals is that they form the plane of *object distance* on which focussing is to be done. The lens axis must be vertical to this plane, and the focussing screen must be parallel to it. The side movement of the camera between the first and second exposures must also be strictly parallel to this plane. The distance between the lens centre and the plane of the verticals is given in every case by the working formulæ and will be called *object distance*. The sharply-defined images of the two verticals must appear on the focussing screen at an exact distance apart, which is also given by the formulæ. This last distance will be called *print width*, and the greatest attention must be given to its accuracy, for on it the scale and distance of the stereo image will depend. This is the third function of the verticals. The prints have only to be made by contact from the negatives, trimmed along the images of the verticals, and mounted side by side with their inner edges touching.

It is important that the images of the verticals should run unbroken from top to bottom of both negatives throughout the height which will appear on the prints. No part of the object in front of the verticals must be allowed to infringe upon them in such a way that it comes between them and the lens and cuts off the view. Otherwise an effect of unreality at the edges of the image, well known to stereo workers, will result. With the exception of this proviso, however, the object may be placed anywhere within the limits of sharp focus. In general, perhaps it will be placed with one-third of its depth on the nearer side of the verticals, and the other two-thirds on the farther side; but if it is wished to concentrate attention upon the surface of the stereo image the object will be placed more or less in line with the verticals, with its main bulk behind them. It should be noted that the use of a small stop is indicated here, especially when a magnified image is to be obtained. The pupil of the eye is very small, and whatever the result of using a large stop may be it will not give a natural effect. The practical necessity of stopping down the lens before exposure in order to secure definition therefore agrees with the *a priori* requirements of theory. The object should not be placed on a wide table, but should be supported on a small block which is itself narrower than the *object width* or distance between verticals. This will make it easier to secure the unbroken image of the verticals on the negatives. A horizontal line, strongly marked on the face of the block, would be of immense assistance in the proper trimming of the prints, as they could be trimmed off along the image of this line, and another difficulty, familiar to stereo workers, would then be removed.

The last part of the photographer's problem is to determine what amount of shift must be given to the camera after making the first exposure, in order to secure the correct degree of perspective relief in the image. This also is given by the formulæ, and will be called *lens separation*. It only remains therefore for the worker to make sure that he moves the camera through exactly this distance. If an ordinary folding camera is used it will be better to attach it squarely to a small rectangular base whose edges may serve as guides. A slip of paper longer than this base should be marked with two parallel lines drawn at *lens separation* apart. An edge of the camera base should coincide with one of these lines for the first exposure, and afterwards moved until it coincides with the second line. Two drawing pins will hold the paper in position during the operations. Great care should be taken that the camera is not moved forward or backward in the slightest degree, and that in changing the plates the adjustment between lens and focussing screen is not disturbed. In the following examples the camera extension or distance between focussing screen and lens centre is given for the convenience of the worker, and assuming that the lens used is accurately 2½ in., this will obviate a good deal of tentative focussing and movements of the camera. If a beginning is made with No. 2 example, where the extension is 3 in., and a mark is put on the focussing scale or other convenient place, the other extensions of 3⅛, 3¼, and 3¾ can be readily adjusted, and the camera may simply be pushed forward towards the verticals until they are in focus. Focussing might be done on a strongly-lined screen temporarily placed in the plane of the verticals, and the supporting block with the object arranged on it afterwards put in position. A pair of compasses, with the points set at *print width* apart, should be used to test the accuracy of the distance between the images of the verticals on the focussing screen. Until this has been satisfactorily secured no exposure should be made.

One more question. Plate or film for the negatives? Without any reference to a recent rather heated controversy, and independently of the respective merits of the two, the nature of the problem before us gives a very definite answer, and indicates that here film negatives will be most convenient, especially if positive transparencies are to be made for use in the stereoscope. Instead of trimming the prints we can then trim the negatives themselves by cutting away all the film that lies outside the images of the vertical lines. The negatives can then be placed side by side on the paper or other surface on which the positive is to be made, and a stereo print directly ready for viewing can thus be obtained by a single exposure. In order to avoid the danger of confusing the left and right negatives a slight modification of this method will be advisable, which will permanently record on each negative the side to which it belongs. For the left exposure a small card bearing the letter L should be placed close to and at the outer side of the left vertical, and removed as soon as the exposure is made. For the right exposure a similar card, marked R, should be correspondingly placed at the outside of the right vertical. There will always be plenty of room on the negatives for the images of these letters, and only one end of each negative—the end not bearing the letters—should be trimmed off. When the two trimmed edges of the negatives are placed in contact they will be in correct position for printing, and no mistake can be made. This will also obviate the necessity of handling the actual part of the negatives which is to form the prints, and the untrimmed ends will provide a convenient means of shifting the negatives into position for printing. No doubt a worker who is expert in the use of a diamond will be able to trim glass plate negatives quite as accurately as films, and if Autochrome transparencies are to be produced this will be necessary. When a series of experimental protographs is to be taken of the same group of objects, as may very usefully be done in the present instance, it will be well to add a distinctive number or mark of some kind under the letters L and R for each pair of exposures, in order to identify them and avoid con-

fusion. The visual difference will sometimes be very small. Unless some precaution of this kind is taken the photographer may inadvertently find himself responsible for the mixed marriages of stereo couples that nature never intended to be joined together.

The mounting or making of the prints side by side and in contact has been assumed so far, because this is the simplest and surest road to accuracy. It is not, however, quite an ideal method, as the eye detects something like unreality where the two prints meet. In mounted prints it will be better to cut an additonal 1/16 in. off both edges of each print, and mount them ¼ in. apart. This will preserve the correct distance between corresponding points in the prints. Transparencies or direct prints should be covered with a mask having two openings whose width is ¼ in. less than that of the prints, and separated by a distance of ¼ in. at their inner edges.

The writer is sensible that the above working hints are only a kind of rough outline of the method by which the photographer may proceed to translate the formulæ into action. They are such suggestions as naturally occur to one with considerable past experience in rigging up apparatus to suit the needs of the moment, but who is at present restricted to the use of a pen. By the time two or three experimental exposures have been made the worker will have attained facility in the routine of operations, and will be very much wiser than his present instructor. At the outset, however, the indications of procedure above given may be of use.

In the following table fractional values are expressed as decimals, and the worker is supposed to have provided himself with a rule divided into tenths and hundredths of an inch, and with needle point dividers by which he will be able to lay off the distances accurately. Just as, when trying a new developing formula, he is careful not to allow a deliberate error of a single grain or minim to enter into his measurements, so he is expected conscientiously to aim at accuracy in the present instance, in order that the method may have fair trial.

Table giving five examples to be taken with 2½ in. lens

Note.—*Object width* = horizontal distance between vertical cords or wires.

Object distance = distance of the camera lens from the plane of the verticals.

Camera extension = distance between focussing screen and lens.

Print width = distance between the images of the verticals as seen on the focussing screen

Lens separation = amount of side shift to be given to the camera.

Of these dimensions the *object distance* and the *camera extension* (which are really only given for convenience) will vary if the lens is not exactly 2½ in. in length The three critical dimensions which must never vary are the *object width*, *print width* and *lens separation*. For a purpose which will be explained below, two additional examples are given. Nos. 6 and 7, which require a 3 in. lens. The distance of the resulting image is given under the letter *x*, and its scale under the letter *n*. In the third example, for instance, *x* = 16 and *n* = 2. This means that the image will be 16 in. from the eyes, and twice natural size. The dimensions are given from left to right in the order in which they claim the attention of the worker.

	x	*n*	Object width.	Object distance.	Camera extension.	Print width.	Lens separation.
(1)	12	1	7.5	12.5	3.12	1.88	2.25
(2)	16	1	10.0	15.0	3.0	2.0	2.33
(3)	16	2	5.0	8.75	3.5	2.0	1.16
(4)	20	3	4.16	7.5	3.75	2.08	0.8
(5)	36	5	4.5	7.5	3.75	2.25	0.5
(6)	20	1	12.5	21.0	3.5	2.08	2.38
(7)	36	1	22.5	33.0	3.3	2.25	2.47

Examples 3, 4, and 5 will show how completely the realisation of these results will depend upon the eyes. In these three cases the scale of the prints is almost the same; in 4 and 5 it is identical. The prints only differ from each other in width, which determines the convergence of the eyes, and in the amount of perspective change between the left and right views. If the observer has to adjust the focus of the stereoscope to suit his sight, and not to suit the image—and this of itself will indicate defective vision—there is very little left by which he can judge. But the optical facts put before him will be accurate, and whether he realises it or not, the image he sees is that which the worker sought to produce: the *technique* will be correct. Nos. 1, 2, and 3 should certainly be successful. No. 4 is doubtful. No. 5 may be regarded as an attempted *tour de force*, intended to test the space limits to which enlarged images of this kind can be successfully projected, and probably to show that these limits have been passed. The taking of No. 5 will give very little trouble, as the camera adjustments and distance are the same as No. 4, and it is hoped that the experiment will be made. In general, enlarged images will only be called for at near distances, and it will be seen later that by the use of a shorter focus lens any degree of magnification can be obtained and the image brought close to the eyes.

It will be a quite different matter, however, when natural-sized images of familiar objects are projected to these distances of 20 in. and 36 in., or even much farther than this; for then the mind can at once recognise what is presented and verify its impressions. Nos. 6 and 7, to be taken with a 3-in. lens, are arranged to correspond with Nos. 4 and 5, but the images are not enlarged. A natural history specimen would make a very suitable object in these cases. The inclusion of a section of an inch rule, graduated clearly, but not too closely—say, into eighths of an inch—would greatly assist the judgment when the image is to be natural size; but this would be quite fatal if the image is to be enlarged. In the latter case a reduced scale rule $\frac{1}{n}$ natural size should be attached to the object to be photographed, so that in the image (magnified *n* times) it will appear in its true dimensions and serve as a guide. In No. 5 a ¼ scale rule should be used, and it may be useful to point out that this can be obtained at the same time that No. 2 is taken, as the negative here is exactly on a ¼ scale. A little ingenuity will enable the worker, by incorporating the image of an inch rule on some waste portion of his negatives—say, on the edge or bottom that is to be cut away—to provide himself with a series of rules of various proportions which will be available for this purpose when magnified images are to be obtained. This dodge for assisting the judgment would seem to be legitimate, and may be found to be necessary

The accuracy of a suggested procedure can quite satisfactorily be tested by finding out whether certain predicted bad results will follow any departure from it. What will happen if we use an entirely wrong lens for taking the negatives? The first effect will be that *object distance* and *camera extension* will vary directly in proportion to the focal length. As regards the image its *depth* will vary inversely to the focal length; its width, height, and distance will remain unchanged. If a 5 in. lens is used for examples 1 to 5, the depth in every case will be only half what it should be—a fully drawn-out concertina will appear half closed. If the 2½-in. lens is used for examples 6 and 7 the depth will be increased by one-fifth. Any lens whatever may be used in any particular case, but only one lens will give an absolutely correct result. This note is added for the benefit of those who wish to try the method, but who may not find it convenient to procure special lenses for the purpose. H. C. Browne.

(To be continued.)

Photographs of War Memorials Wanted.—For the compiling of a photographic record of all war memorials erected in the United Kingdom and Colonies, the Imperial War Museum, Crystal Palace, S.E., requests all authorities concerned to kindly supply photographs. These should be on mounts 8 inches by 5 inches, with the date of the unveiling ceremony, name of sculptor, and any other details of interest inscribed on the back

FORTHCOMING EXHIBITIONS.

January 11 to 27.—Camera Portraits, entitled "Men of Mark," by Walter Stoneman, at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1.

January 21 to February 4.—Partick Camera Club. Particulars from the Hon. Secretary, James Whyte, 51a, Peel Street, Partick, Glasgow.

February 7 to 11.—Sheffield Photographic Society. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield.

February 11 to 25.—Scottish Photographic Salon. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Latest date for entries, January 30. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Latest dates, entry forms, February 4; exhibits, February 9. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Latest dates: Entry forms, February 15; exhibits, February 23. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 26.—Welsh Salon of Photography. Latest date for entries, March 9. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

TRANSPARENT PANEL ENVELOPES.—In a notice which was recently issued by the Postmaster-General reference was made to the introduction of more stringent regulations affecting the use of transparent panel envelopes. Those regulations, which came into force on January 1 last, are not being generally observed, and, in consequence, many letters in panel envelopes are being stopped in the post. The Postmaster General therefore wishes to draw renewed attention to the restrictions. The transparent panel must form an integral part of the envelope and must be parallel to the longer side, so that the address appears in the same direction; it must be placed so as not to interfere with the impress of the date stamp, and must be of a substance that will take writing. Articles forwarded in envelopes with a transparent panel must be registered. As a modification of the conditions, the Postmaster-General has arranged that in the case of envelopes addressed to any part of the British Empire or to the United States of America the panel need not form an integral part of the envelope.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 9 to 1 :—

FILMS.—No. 791. Treatment of photographic films with solutions.—R. E. Crowther.

COLOUR PHOTOGRAPHY.—No. 1,052. Manufacture of multi-colour screens for natural-colour photography.—P. Faulstich.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINTING AND ENLARGING MACHINES.—No. 170,427. (July 30, 1920). The invention relates to photographic printing apparatus in which one rotation of an actuating shaft effects a complete cycle of operations, the shaft having mounted thereon cams which operate the contact plate for pressing the intermittently fed continuous strip of sensitive paper against the negative, and which (also while the paper is stationary) actuate mechanism to automatically switch on and off electric lamps contained in an enclosed chamber, means being provided to regulate the duration of the exposure.

The closing down of the presser plate is affected mechanically by the rotation of a cam shaft by which rotation pneumatic means for closing the electric circuit (thereby switching on the light) are simultaneously operated.

A machine provided with mechanism according to the invention is illustrated in the accompanying drawings and will be described in relation thereto.

The machine is constructed with a table top 8 supported upon a framework 9 within which is fixed a box 10 forming the printing frame and opening at its top through the table top. When the machine is used for ordinary printing the frame has

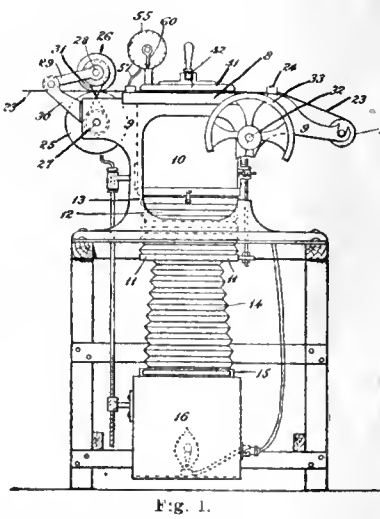

Fig. 1.

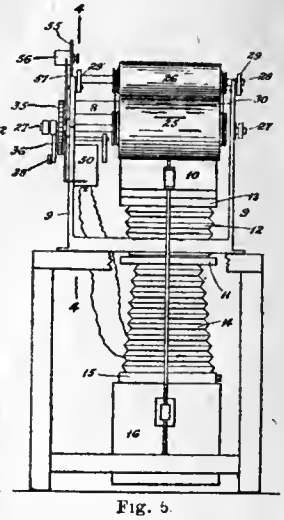

Fig. 5.

a negative holder placed within its open top: if it is desired to use it for enlargement work an enlarging apparatus is secured to the opened bottom end of the frame as shown in figs. 1 and 5.

For contact printing, the enlarger is removed and the open bottom of the box 10 covered so that this box then serves as the light box to throw the printing light up through the negative placed in the open top thereof.

The enlarging apparatus comprises a lens frame 11 connected by bellows 12 with an upper frame 13 and by bellows 14 with a negative slide holder 15 and light-box 16 below. The lens frame 11 and the light-box 16 with the negative holder 15 are relatively adjustable in their distance from each other and from the top of the printing frame so as to vary the size of the

image thrown by the negative through the open top of the printing frame

The strip of paper 23 passes from the roller 22 through adjustable guide blocks 24 along the top of the table 8 and across the open top of the printing frame.

At the other end of the machine frame are arranged the feeding rollers 25—26. The roller 25 has a spindle 27 mounted in the frame 9 and the roller 26 is carried on a spindle 28 mounted in arms 29 pivoted to brackets 30 upon the frame 9, so that this roller rests with its weight on the periphery of the roller 25 in

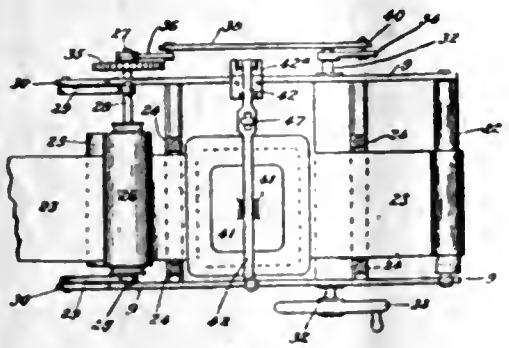

Fig. 2.

order thereby to effect a grip upon the paper strip. The two rollers are connected by crossed belts 31, arranged one at each end, so that the rollers when rotated in the proper direction will draw the paper strip from the roller 22, across the table top and out through between them.

For operating the feed rollers 25 and 26, a power shaft 32 has a hand wheel 33 on its front end and a crank arm 34 secured on its back end (see fig. 3). The spindle 27 of the roller 25 has a ratchet wheel 35 secured upon its back end and an arm 36 mounted loosely thereon and carrying a spring-controlled pawl 37 which engages the teeth of the wheel 35. The arm 36 is connected by a rod 38 with the crank arm 34 so that by the rotation of the shaft 32 the arm 36 will be reciprocated and thereby turn the feed rollers intermittently. The amount of turning movement given to the rollers on each rotation and consequently the length of paper fed across the printing frame at each printing operation can be regulated by adjusting the point of attachment of the connecting rod 38 to the crank arm 34 by adjusting and securing a screw pin 40 in a longitudinal slot 39 in the arm.

A presser plate 41 is mounted above the top of the printing frame and is adapted to cover the whole opening thereof and make light-tight contact all round its edges. This plate is pivotally mounted upon a lever 42 extending from back to front of the machine and pivoted at its back end to a standard 42a so

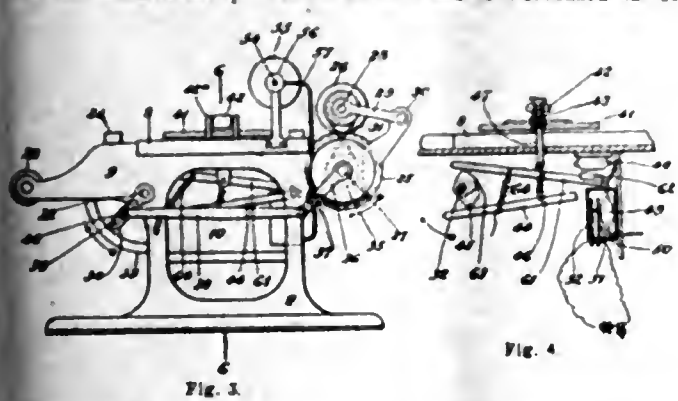

Fig. 3.

Fig. 4.

that it may turn up and down thereon. The pivotal attachment of the plate 41 to the lever 42 provides that when the lever is pressed down the plate will engage evenly around all the edges of the printing frame. The lever is kept normally raised free of contact with the frame by means of a spring 43. Thus the paper strip 23 may be passed beneath the plate 41 and fed across the table when the plate is thus raised. The plate 41 is depressed on to the frame and the light is simultaneously switched on at each printing operation in alternation with the feeding movements of the feed rollers 25—26 by means which will now be fully described.

These means are shown more particularly in figs. 3, 4 and 6 and comprise a lever 44 which is pivoted at one of its ends to the frame 9 and at its other end underlies a cam 45 secured upon the operating shaft 32. About midway of its length the lever is connected through a helical spring 46 with the lower end of a rod 47 which passes vertically up through the table 8 and is connected at its upper end to the presser plate lever 42. The spring 43 keeps the cam lever 44 drawn up against the cam 45 and the throw of this cam is so adjusted that the lever 44 will be depressed sufficiently to draw the plate 41 hard down on to the printing frame with a resilient pressure caused by the interposition of the helical spring 46 between the rod 47 and the cam lever 44.

The connection of the rod 47 with the lever 42 is made in such a manner as to provide for the lever being freed from the rod 47 in order to permit of the lever and plate being turned back on the hinge 42a to allow of the printing frame being arranged for printing. This may be effected for forming the rod 47 with a T head and passing it up through a slot in the lever 42 as shown in figs. 2 and 6 so that when turned across the slot it will engage the sides thereof and when turned lengthwise, the lever may be lifted clear of it. The spring 43 is kept in position by arranging it around the top end of the rod.

This operation of the presser plate 41 is adjusted to take place during the idle return stroke of the paper feeding mechanism and simultaneously therewith the light within the light-box is illumined for the predetermined period required for the exposure

The means for performing this latter operation are shown in detail in figs. 4 and 7 and consist in a rubber air bulb 48, having a non-return air inlet valve, of well known type, connected by tubing with a rubber ball 49 contained within a casing 50 fixed

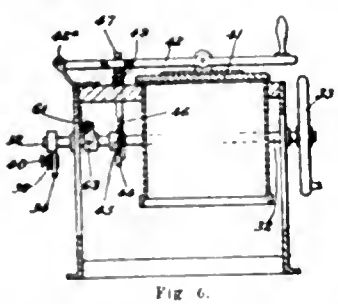

Fig. 6.

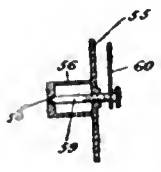

Fig. 7.

to the frame 9. Within the casing are arranged spring contacts 51—52 normally kept apart by their inherent tension and respectively connected with the two poles of the lamp circuit (as indicated by the diagram in fig. 4). The ball 49 is positioned between the side of the casing 50 and one of the contacts 51 so that when expanded by the forcing of air into it, the contact 51 will be forced into contact with the contact 52 and thereby close the circuit. The air then escapes from this ball, to break the contact, through the valve 54 shown in detail in fig. 7. This is combined with an indicator dial 55 fixed to the back of the machine above the top thereof, the dial forming the front end of a small cylinder 56 into the side of which a tube connection 57 with the ball 49 enters. The back end of the cylinder 56 has a tapered aperture 58 therein and a needle valve stem 59 screws axially through the front end of the cylinder and enters this aperture so as close it more or less according to the position of the screw. The outer end of the screw is provided with a pointer 60 passing around the face of the dial 55. The positioning of this pointer at different positions upon the dial will therefore indicate different degrees of opening of the needle valve and consequently give an indication of the times taken in the escape of the air from the ball 49 when the needle valve is in such positions. Consequently, it becomes an easy matter to set the valve to provide for the lamp circuit remaining closed for any period desired after the ball 49 has been inflated to close such circuit.

The rubber air bulb 48 is compressed to close the lamp circuit by means of a lever 61 pivoted at about midway of its length to the frame 9. One end of the lever underlies the bulb 48 and has a bread plate 62 fixed thereon to engage the bulb and the other end overlies a second cam 63 fixed on the operating shaft 32. The latter end is spring-controlled by means of a

spring 64 connected to it and to the frame 9 so as to keep it in close contact with the periphery of the cam. The cam 63 is so shaped and is so adjusted on the shaft 32 that during the paper feeding portion of the rotation of the shaft the level 61 will be turned to free the bulb 48, and during the other portion of such rotation it will be turned by the spring 64 so as to engage and compress the bulb 48 in the required manner.

Thus the one rotation of the operating shaft 32 will effect at the required time the depression of the presser plate 41 on to the printing frame simultaneously with the operation of the exposure light.—Matthew Marrin Kulus, Karangahape Road, Auckland, New Zealand.

New Books.

THE RED BOOK.—The indispensable Red Book of the Affiliation of Photographic Societies has again appeared well in advance of the photographic season. Under the editorship of Mr. George Hawkings, its customary features have been preserved and extended, and its advertisement pages afford a wide survey of the requisites available for the amateur photographer. Landscapists will be interested in the little article in which M. Leonard Misonne tells of his aims in landscape work and of the technical processes he uses in producing the works of such distinctive charm by which he is known. It should not be necessary to point out that possession of the Red Book serves as a permit to photograph in many places in London and the Provinces. The volume also contains a long list of photographic lecturers and their subjects.

COMMERCIAL PHOTOGRAPHY.—Our publishers inform us that they have just issued a fourth edition of this little manual by "Practicus," dealing with the branches of practical work which customarily come within the scope of the commercial photographer The book is no doubt well known to many of our readers, since the sales of the three previous editions have been considerable. Still it may be pointed out that the manual advises on the choice of equipment for commercial photography and on the special manipulation for subjects, such as houses and gardens, shop fronts, paintings and furniture, machinery and motor vehicles, silver, china and glass goods, textiles and clothing, and has something to say on working-up for catalogue illustration and on the everlasting question of how much to charge. The fourth edition is issued at 1s. net, and is obtainable from Messrs. Henry Greenwood and Co., Ltd., 24, Wellington Street, London, W.C.2, price 1s. 3d. post free.

SOFT-FOCUS LENSES.—Although entitled "Soft Focus Effects in Photography," No. 184 of the "Photo-Miniature," just published, is substantially a manual of the properties and use of soft-focus lenses. Mr. John A. Tennant is to be congratulated on having brought together a great deal of information, æsthetic, practical and commercial, on this very topical subject. Situated as he is in the United States, he has been able to collect particulars of the many soft-focus lenses originated in that country. At the same time he has not neglected to report upon the instruments of British and Continental opticians The manual leads off with a short account of the genesis of the soft-focus movement in photography and then proceeds to consider the optical methods of producing such diffused definition, the special considerations required in the lighting of portraits, and the making of soft-focus enlargements and enlarged negatives from originals which were sharp in the first instance. Then follows a collection of opinions on diffused definition by professional portrait photographers and amateur pictorialists. The manual concludes with a survey of the soft focus lenses on the American and European market, and with a brief description of other devices for mitigating the acute definition of a perfectly corrected lens. In the latter connection it is interesting to notice that the Eastman Kodak Co. have at length placed on the market the diffusing discs of the kind originated for use with the Eastman projection printer. We believe those employed for the enlarging lens in this latter outfit were found not the best for direct use on a camera, and that the camera type, now being placed on the market, is the result of considerable further experiment. We are quite sure that both professional and amateur photographers will eagerly add this little handbook on a subject of great present interest to the many issues of the "Photo-Miniature," which in the past have provided much valuable help. Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, publish in this country, price 1s. 8d.; in America Messrs. Tennant and Ward, 103, Park Avenue, New York, price 40 cents.

New Materials.

CRITERION PROFESSIONAL MATT BROMIDE PAPER.—Professional photographers will appreciate the quality of the new paper just issued by Messrs. Criterion Ltd., Stechford, Birmingham, as "Professional Matt Bromide." For one thing, it has an excellent and distinctive matt surface, almost indistinguishable from the natural surface of the paper. It is also made in three grades of contrast—ordinary, hard and extra-hard—a very positive advantage in dealing with negatives varying considerably in vigour. The papers work with great cleanness in any of the ordinary developers, yielding prints of excellent black tone and purity of whites. Samples and prices are obtainable by *bona-fide* professional photographers on application to Messrs. Criterion Ltd.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 24, Mr. E. W. Mellor in the chair.

Mr. C. M. Thomas, M.A., delivered a lantern lecture, "The Plate and the Photographer," a title (apparently not the lecturer's) which very inadequately described the subject of the discourse. Mr. Thomas talked of the physical and sensitometric properties which are possessed by a dry plate. The commendable aim of the paper was evidently to temper the strong wind of Hurter and Driffield to the shorn pictorial lambs. Yet he did not come to a downright declaration of this motive until he responded to the vote of thanks. Then, he envisaged photographers as divided into two camps, [illegible] on opposite sides of a chasm—the scientific people with their eyes fixed on gamma infinity, and the pictorialists bent on their [illegible] to the disregard of the scientific basis of the processes they used. Was there a bridge across the chasm? Yes, answered Mr. Thomas, in both camps the S-curve [illegible] for different [illegible].

It is impossible to report the substance of the lecture in the absence of the numerous diagrams and lantern [illegible]. Mr. Thomas started off by showing a simple form of density measuring instrument of his design and construction, suitable and sufficiently accurate for the measurement of negatives by the practical photographer. He proceeded to illustrate, alternately by curves and by negatives and transparencies therefrom, the properties of negatives [illegible] long and short range of densities. In like manner he sought to [illegible] side by side the diagrammatic and pictorial statements of the [illegible] and latitude of a plate, and passed in conclusion to some [illegible] illustrating the grain of an emulsion. A paper such as [illegible] should do much towards making results expressed in sensitometric language more accessible to those who regard curves and [illegible] as something incomprehensible. A hearty vote of thanks [illegible] accorded to the lecturer.

CROYDON CAMERA CLUB.

Mr. L. J. Hibbert—[illegible] "formed the crisp if [illegible] informa[illegible] for last week's meeting. It proved to relate [illegible] to [illegible] nor decimals, but to process blocks, the making [illegible] which was described in admirably clear [illegible]. Why they are [illegible] and how they are done, was also explained in [illegible].

[illegible]

[illegible] PHOTOGRAPHIC ASSOCIATION.

[illegible]

[illegible] members [illegible] the hope that [illegible] would be completed [illegible]

The Chairman [illegible] certain [illegible].

Mr. [illegible] seconded [illegible] that the present officers and [illegible] nominated for election [illegible] annual [illegible]

[illegible]

call themselves now an incorporated body but he had still to lodge the last form, and then the Registrar would issue a certificate. As soon as the last form was lodged they could get the authority to carry on business. He had still to get one or two signatures, and after these had been secured it would only be a question of a few days' delay. He would advise the Treasurer as soon as the formalities had been completed. In March the only business the old Association would have to do would be to pass a resolution to dissolve, but somebody had to have authority to call that meeting, therefore the old Association required its officers until then. The seal ought to be kept by the Secretary: it was usual to keep it in a box with two locks, two members of the Council keeping the keys. A minute book must be procured. The annual general meeting in March might be called for the same time and place as the first general meeting of the registered Association. All the notices could go out together.

The Secretary reported several cases in which members during the past month had sought advice and guidance. In one case where a member had, through the medium of the Association, recovered damages from a second-hand apparatus dealer, after deducting all out-of-pocket expenses, he had forwarded, with a covering letter of appreciation, the surplus cash as a donation to the funds of the P.P.A. (Applause.)

Before the Council rose the Chairman reported that three members of the Association had been returned winners of the 1st, 2nd and 3rd prizes in the Wellington and Ward Professional Portraiture Competition. Mr. Angus Basil (present), winner of the first prize, was heartily congratulated by his fellow-councillors. After a sitting of 3½ hours the Council adjourned.

Cambridge Photographic Club.—On Tuesday, January 17, Mr. T. H. B. Scott, president of the East Anglian Federation of Photographic Societies, who brought down the Federation Portfolio, gave an address on pictorial photography. By a fortunate chance Mr. Edward Peake, late of Norwich, who was really the founder of the Federation, was present, he having recently come to live in the neighbourhood of Cambridge. Mr. Scott gave an extremely interesting address. He has strong ideas of his own as to the relative importance of the rules of composition and "natural effect." He does not care anything about the "one-third from the top and one-third from the right-hand side business," so long as the picture shows the "something" that means individual thought and feeling. As an illustration of this Mr. Scott displayed one of his own pictures—one of a mean lane in Beccles, in which the ugliness of the buildings was lost in a beautiful effect of sunshine. He gave a brief sketch of the history of the East Anglian Federation. No other body or movement had done so much to raise the position of photography, said Mr. Scott. The movement was due to Mr. Peake, who suggested that the Federation should take for its motto that of the old Norwich School of Painters—"For Air and Space" Since the war there had been difficulty in getting things going again, but the speaker said he saw signs of a revival, and he appealed to the members of the Cambridge Club to help to carry on the good work.

Mr. Peake, in a short but impressive speech, strongly urged members to strive for natural effects. He concluded by saying that he would be proud to become a member of the club and to do all he could for it.

The Secretary, Mr. Wm. Farren, in proposing a vote of thanks to Mr. Scott, referred to the pleasure it gave to him and to the other old hands to have Mr. Peake with them, and to hear that there were signs of a revival of the East Anglian Federation. He also announced that Mr. Peake had consented to act as judge at the annual exhibition of the club, which is being held at the end of February.

The "Blackpool Times."—Messrs. Pictorial Machinery, Ltd., 7, Farringdon Road, London, E.C.1, inform us that the improved method of newspaper production adopted by the "Blackpool Times," and to which reference is made in a paragraph on another page of this issue, has been carried out in connection with their "Lithotex" plant, supplied to Messrs. Robertson, proprietors of the "Blackpool Times."

Commercial & Legal Intelligence.

Legal Notices.—Notice is given that a general meeting of the members of the United Service Studios, Limited, will be held on February 21, at 11 o'clock, at 13, Queen Street, Cheapside, E.C., for the purpose of considering the liquidator's report, showing the manner in which the winding-up has been conducted, and the property of the company disposed of.

Notice is given of the dissolution, by mutual consent, of the partnership between Jessie Emma Noon and Ernest Alfred Clark, carrying on business as picture frame makers, etc., at 20, St. Nicholas Street, Leicester. All debts due to and owing by the late firm will be received and paid by Ernest Alfred Clark.

NEW COMPANIES.

William Fox & Sons (Sheffield), Ltd.—This private company was registered on January 14, with a capital of £5,000 in £1 shares. Objects: to carry on the business of photographers and opticians, etc. The permanent directors are:—Mrs. M. Fox, The Grosvenor, West Cliff, Bournemouth; A. R. Fox (chairman), 15, Silver Hill Road, Sheffield. Qualification: £500. Remuneration: £300 each per annum. Secretary: A. R. Fox. Registered office: 8, Castle Street, Sheffield.

A. H. Development Syndicate, Ltd.—This private company was registered on January 16 with a capital of £100 in £1 shares. Objects: to carry on the business of engineers, manufacturers of all kinds of apparatus, whether mechanical, automatic, photographic or otherwise, etc. The first directors are:—E. S. Hunter, Ruben's Hotel; Buckingham Palace Road, S.W.; E. K. Hunter (permanent), 74, Primrose Mansions, Battersea Park, S.W.11 (directors of Hunters, Ltd.). Remuneration: £100 each per annum. Registered office: 16-18, St. Bride Street, E.C.

News and Notes.

Mr. Geo. J. Hughes, F.R.P.S., having disposed of his business known as Hughes & Co., Ltd., art photographers and photographic dealers, The Mall, Waterford, and Park Studio, Dungarvan, has now taken over the studio, Bridge-of-Allan, Stirlingshire, Scotland.

XL Printing Appliances.—Messrs. F. Brodrick, 50, High Street, London, W.C.2, have just issued an abridged price list of their chief appliances for printing, developing, fixing and washing of plates and films. One specialty is a printing box for the printing of amateurs' film spools. It is fitted with masking and self-numbering devices. Among other of these very workmanlike appliances is a teak cascade print washer of the pattern which we think is quite the best for the washing of large numbers of prints.

Royal Institution.—Among the evening and afternoon lectures to be delivered at the Royal Institution are "The Mount Everest Expedition," by Sir Francis Younghusband, on February 3; "Pigments and Mediums of the Old Masters," by Professor A. P. Laurie, on March 17. Dr. P. Chalmers Mitchell is to give two lectures on "The Cinema as a Zoological Method," on March 16 and 23, and among the art subjects Dr. E. A. Gardner will lecture on "Masterpieces of Greek Sculpture" and Mr. Arthur M. Hind on "Landscape Etchers, New and Old."

Hampshire House Photographic Society.—The annual exhibition of this Hammersmith Society will be held from April 21 to May 11. There will be three open classes for prints, monochrome slides and transparencies and colour transparencies. The judges are Messrs. Marcus Adams, Bertram Cox and Leonard Richmond, who will have at their disposal a number of certificates for work of outstanding merit. The last day for receipt of entries is March 30. Entry form and particulars from Mr. J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, S.W.6.

Photographs of Lincoln's "Imp."—A writer in one of the daily papers states that many of the photographs of the grotesque figure in the nave of Lincoln Cathedral, and known as the Imp, are

made from a model which at one time was kept by an enterprising verger. The real figure is in an awkward place for photographing, and on hearing the lamentations of photographers the verger procured a "life like" model which he, on request, hung at eye level in a convenient corner of the Cathedral. This, no doubt, was before the days of telephoto lenses.

THE FLORENCE BOOK FAIR.—In this exhibition, to be held at Florence from May to July next, photographic and cinematograph exhibits will be accepted in a special section. British exhibits at the Fair will be in the charge of an officer of the Board of Trade, whose expenses will be apportioned among the exhibitors. The Fair is being held in the rooms and gardens of the beautiful Pitti Palace. Particulars of charges for floor or wall space are obtainable from the British-Italian Commercial Association, agents in Great Britain for the British Chamber of Commerce for Italy, 12, Nicholas Lane, London, E.C.4.

SHOE-BUCKLE PORTRAITS.—A Montreal paper reports that Canadian "flappers" have discovered a sure way to bring the men to their feet. The new cue is to mount the picture of your "boy" on a colonial shoe buckle. Thus his subjugation is advertised to the world. When one is equally "keen" about two men the solution is simple. One has two feet. Assign each a buckle, awarding the favourite the right-foot position. When a new picture appears, the "flapper's" social set will invite the "original" as her escort. Thus an evening spent with a man she "just detests" is happily avoided.

ITALIAN OFFICIAL PHOTOGRAPHS.—Under the auspices of the National Propaganda Office, 4, Via Piatti, Milan, there has been instituted an "Italian Photographic Service for the Foreign Press." The object is to supply the principal illustrated journals of the world with photographs of current events in, and of the artistic and natural beauties of, Italy, and to illustrate the modern development of the country. It is hoped in this way not only to interest the Press and peoples of the world in Italy and her problems, but also to prevent and combat the traducing campaigns conducted at present through misleading or actually fraudulent photographs.

THE CAMERA AS A WITNESS.—The recent boxing match between Carpentier and Cook at the Albert Hall was well photographed, and some very fine prints from the negatives have been reproduced in the Press. The cinematograph film served to settle a disputed point, it being stated by some observers that a foul blow was struck. It was thought that Carpentier gave the knock-out blow when Cook was down, but a careful examination of the films by experts proves that the defeated boxer's knees had not touched the floor—though they were rapidly approaching it—at the time it was struck. Thus the camera repudiates the unfounded suggestion of a foul, and most of the critics are quite satisfied that the finish of the fight was a perfectly fair one.

AT THE HALCYON CLUB in Cork Street there is a small exhibition of photographs and artistic objects which may be classed as modern minor arts. The greater number of the photographs are by Miss Agnes B. Warburg, whose work here shows to great advantage. It is straightforward and technically sound. Perhaps the best picture of the whole is "The Tolsey, Burford," the tone values of which are so true as to secure it life and luminosity. In "Conway Castle" Miss Warburg avoids the usual danger of making a silhouette effect at the expense of interest and definition in the dark object. The exhibition closes on the 30th instant. We were invited, but we presume any visitor would be welcome who could pass the Cerberus at the door.

KODURA ETCHING BROWN ENLARGEMENTS.—Messrs. Marshall & Co., Mansfield Road, Nottingham, a firm of enlargers and trade workers maintaining a standard of distinctive quality, send us an example of a new style of enlargement which they are now offering to supply. This new special line is an enlargement on Kodak "Etching Brown" Kodura paper, 9½ x 7½ inches in size and presented in a folder mount of most agreeable buff tint, with tissue covering for the print. Outside dimensions of the folder are 14 x 10 inches. The photograph is of fine quality, and would certainly be taken for a direct print. In the size just mentioned, Messrs. Marshall supply at the price of 4s., or in whole-plate at 3s. 6d. It is quite a welcome and most artistic addition to the styles of enlargement which photographers may obtain from the trade houses.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—We are glad to notice that our Birmingham friends are getting into their stride again and are holding the first open exhibition since the outbreak of war. It will be the 31st, will be held at the galleries of the Royal Birmingham Society of Artists, New Street, and will, no doubt, rank in importance with the exhibitions of former years. The selection committee consists of Messrs. Harold Baker, J. C. Batkin, W. A. Clark, Harold Holcroft, Bernard Moore and J. W. Moore. Mr. F. J. Mortimer will judge the pictorial classes; Mr. R. Hancock those of scientific and technical exhibits, and Mr. A. J. Leeson the survey exhibits. Medals and certificates are at the disposal of the judge in each class. The prospectus has now been published and is obtainable from Mr. Philip Docker, Birmingham Medical Institute, Edmund Street, Birmingham. The last date for the receipt of exhibits is February 25. Entry forms require to be received by February 15.

THE ACME ART ASSOCIATION.—It is not often, we imagine, that a firm receives an order for nearly 40 ivory miniatures of members of a single group of families. On hearing from the Acme Art Association that they had recently executed such a commission, we gladly accepted the firm's invitation to look at the collection at its studios at 342, Camden Road, London, N.7. We were pleased and interested in examining the work, which has been done by the firm's own artists, and reflects the greatest credit upon them, not only as regards the technique of the art of miniature painting, but also in respect to what is often a more important matter, namely, the preservation of the likeness. We would not wish to have miniatures which are more acceptable in respect to these two qualities than those which have been made in the present instance by the Acme Art Association. After all, the perfection of the work is only what is to be expected from a firm which, for more than twenty years, has specialised in miniature painting, with and without photographic basis, on ivory and ivorine. We congratulate the company on this most practical form of tribute to its reputation. It may perhaps prevent any misapprehension which this reference to the firm's work may create, if we add, for the information of those who have not had transactions with it, that the Acme Art Association undertakes the making of coloured portraits in all the customary media—water colours, pastel and oils—both freehand and on a photographic basis. Its work in these various branches is distinguished by a refined sense of colouring, and evidently also by a lively recognition of photographers' requirements. In making a little tour of the studios, we saw work in hand for a number of photographers whose names are household words—it would not do to say what they are—so that we are in the happy position of feeling that our appreciation of the work of the Acme Art Association is shared by leading photographic portraitists.

BEACH PHOTOGRAPHY.

To the Editors.

Gentlemen,—In answer to a correspondent on page 44, January 20, of the "B.J." you reply "that the local authority has power to prevent anyone from taking photographs."

I know that beach inspectors do order camera users away, and I should be glad to know if any of your readers have successfully contested the rights of local authorities to make such prohibitions.

Are the local foreshore by-laws countersigned by the Home Secretary, or how are they made legal? I am not concerned with the man who runs a dark room on the beach, but one who has a shop in the town, and sends operators with hand cameras.—Yours faithfully,

ONE HUNDRED AND ONE.

THE P.P.A. CONGRESS.

To the Editors.

Gentlemen,—I have been a member of the P.P.A. practically since its inception, and feel bound to express my strong disapproval of the action of the Council in moving the date of the Congress from May to September, thereby depriving many Scottish photographers of the opportunity of visiting both shows.

There are not many of us who, in these depressed times, find it convenient to make a double journey from the North. Possibly the Council do not think it worth while considering the Scottish members, as they are not usually largely represented, but it would be interesting to know how the President (a Scotsman) looked on the matter, and what his views, if expressed, were.

I have heard it whispered that one of the principal reasons for the change is because it is not convenient for Americans and other photographic dignitaries to attend in the spring. If it is the attitude of the Council to give preference to these shining lights from overseas, I am not surprised to hear of the big falling off in membership.

I have not yet received the form of application for membership of the P.P.A. of Great Britain and Ireland, Ltd., to which "An Old Member" humorously refers, but I beg to suggest, sirs, that unless the policy of the new company harmonises better with the interests of country members, the new company will not only be Ltd., but also, I venture to think, "Very Limited."

Personally, I shall attend the Fair, and hope to travel South on April 30 with my wife, but to say we are disappointed is to put it mildly—Yours faithfully,

SCOTTIE.

COLOUR PHOTOGRAPHS OF STAGE PLAYS.

To the Editors.

Gentlemen,—With reference to the letter from Mr. T. J. Offer in your issue of the 13th inst., photographs in colour of stage plays were taken several years ago by the late Dr. E. F. Grün, of Southwick, near Brighton. He used the special lens of his own design, working at an aperture of f/1.5, and a good many of his experiments were made at the Brighton Theatre Royal. Some of the results were quite good. Dr. Grün and Mr. Jumeaux worked together in colour photography, and I believe had a process of their own.—Yours truly,

A. H. C. CORDER.

36, Mount Zion Place, Brighton.
January 21.

INVENTIONS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I am sure that Mr. Butler, whose letter appears on page 771 of the "B.J." of December 23, 1921, acted in good faith when he applied for a patent on my "Kromskop" optical system with plate-holders attached; but a sufficient answer to his statement that "it was neither designed for nor capable of taking tricolour negatives" is found in the fact that the title of my U.S. patent for the invention (issued December 18, '94, No. 531,040) was "Photochromoscope and Photochromoscope Camera," and that in previous patents and publications I had pointed out that optical systems calculated to blend the images to the eye would also serve to make the original photographs. My original one-plate photochromoscope was described in the "Handbook to the Photochromoscope" (London, 1894) only as a viewing instrument, but in the U.S. patent it was described as a "camera" which could also be used as a viewing instrument.

Much has been made of the fact that my patent drawings showed no plate-holders attached, but that was true of half-a-dozen cameras which I patented, the Patent Office not requiring that they be shown in the drawings because the method of constructing and attaching plate-holders was "well known in the art," and I claimed no invention therein. B. J. Edwards was another who applied for a patent for the system with plate-holders attached, and the Comptroller of Patents, on my protest, refused to grant the patent, declaring that the invention was mine.

This type of camera does not give three perfectly registering images if the reflectors are plane-parallel. I patented three methods of eliminating this defect, and disclosed two others without patenting them—all perfectly efficient, though not equally desirable for adoption in the commercial manufacture of trichromatic cameras. Incidentally, I may say that I patented nine different types of single-exposure trichromatic cameras, all of which operated satisfactorily. Making trichromatic cameras "register" is one of the simplest "problems" I have had occasion to attack. The most difficult problem was to find a way to make them simple enough and cheap enough to popularise trichromatic colour photography. My "Tripak" and "Hiblock" systems came nearer than anything else to meeting this requirement, but met with insufficient appreciation and encouragement to sustain the Corporation which undertook to exploit them. I have no doubt that a less ambitious effort, not involving the overhead cost of elaborate office equipment and business system would, with wise management, meet with modest and increasing success, but there appears to be no very substantial interest in the subject up to the present time.—Very truly yours,

F. E. IVES.

1,327, Spruce Street, Philadelphia, January 7.

SHARPENING RETOUCHING PENCILS.

To the Editors.

Gentlemen,—In the article on "Retouching Materials" in this week's "B.J." the writer describes two methods of sharpening pencils on glasspaper. A good many years ago I spent several years in a Clyde shipyard, and in the drawing office, where some of the finest detail mechanical drawing which I have ever seen was turned out. We all used files for sharpening our pencils to a chisel point, and this is almost the invariable practice on the Clyde.

Though I have no claim to be an expert retoucher, I invariably use a file to sharpen the pencil. It is clean and quick, and I have never found any difficulty in avoiding breakages. If an extraordinarily smooth finish to the lead is required this may be obtained by very lightly finishing on a piece of ground glass. So many text books recommend glasspaper that the use of a file, which is often preferred, does not appear to be widely known.—Yours faithfully,

A. H. HALL.

1, Eliot Vale, Blackheath, S.E.3.
January 22.

TRIMMING AND MOUNTING STEREOGRAMS.

To the Editors.

Gentlemen,—The curious ignorance that prevails about the preparation of stereograms was recently illustrated in a remarkable manner to the writer, when a professional photographer actually expressed his astonishment at being informed that after trimming the prints require transposing. He not only confessed that he was entirely ignorant of this well-known fact, but stated that he had printed and mounted dozens of stereograms for customers, without ever transposing, nor had he ever had a complaint. In view of the fact that the results must have been preposterously pseudoscopic, the circumstance shows that not only this photographer, but many of his customers, must have failed altogether to realise what the stereoscopic effect is really like. The reason for the need of transposition sometimes puzzles beginners, but if they would only bear in mind that the two images are, each of them, inverted in the camera, they would realise that when the double print is turned from this upside-down position, the view that belonged to the right-hand lens will necessarily be brought over to the left-hand, and that which belonged to the left lens will be on the right, so that the two must be transposed to get them to their proper positions.

A second frequent fault in stereograms is that the pairs are so often placed too widely apart. This occurs in the endeavour to get as much in the picture as possible. They are very commonly cut to a width of 3 inches. Leaving, say, a quarter of an inch between them in the middle, this means an actual separation of $3\frac{1}{4}$ inches. To the practised eye it may not be difficult to combine such pairs in the stereoscope, but to many people it is a severe strain to do so, and some little time has to elapse before they can make the two views blend into one.

The ideal limits for perfectly easy combination are a maximum of $2\frac{3}{4}$ inches between the farthest distance points in the pairs and a minimum of $2\frac{1}{2}$ inches between corresponding points in the nearest foreground of the scene. By keeping within these limits a stereogram

...y be ensured that will immediately give full relief effect in the ...oscope to any normal pair of eyes. The separation must, of ..., take into account any central margin space that may be left ...tween the pairs on mounting.

A third essential in trimming an ideal stereogram is that the ...-hand picture should include a little more of the portion to the ...me right in the view, and conversely that the right-hand pic... should include a little more of the portion to the extreme left. ...is condition secures a view in the stereoscope that is behind the ... of the card. On the other hand, if an extended view to the ... is allowed in the left-hand picture, and to the right in the ...-hand picture, the combined view will appear in front of the ..., giving an unnatural effect. The reason is clear: If we look ... a scene through an open window, using each eye successively, we ... see with the left eye further to the right, and with the right ... further to the left. Hence, by reproducing that arrangement in ...ming stereoscopic pairs we get the effect of seeing the com... view as through a frame or window, which is pictorially ...factory.

There are, of course, other essential points in trimming and mount... stereograms to the best advantage, such, for example, as ensur... that corresponding points are perfectly in line, that the two ... are equally printed and smoothly mounted and so forth, but ... elementary desiderata make their own appeal to common... and scarcely call for special allusion even to a tyro.—Yours ...fully,

C. E. B.

THE INCOMPETENCE OF THE AVERAGE PHOTOGRAPHIC ASSISTANT.

To the Editors.

Gentlemen,—It is perfectly amazing how little the average person ...o applies for a post knows about the job he or she is applying ... For quite a long time I have been looking for a really com... ...inisher (lady) in monochrome, and I have interviewed and ... specimens of work from dozens, and I cannot find one—at any ...ice. It is the same in other departments; there must be some... ...extraordinarily wrong in the present methods of training. This letter is prompted by my having just turned away the ...eenth applicant—an ordinarily intelligent and educated girl ... has just finished a "three years' apprenticeship" with a high... West-end studio—for the munificent salary of 15s. a week! ... what has she learnt? "A little about everything." Yes, very ... But anything sufficiently well to be of any future use or to ... her another job at the present time? I doubt it.

The L.C.C. Trades School at Queen Square has turned out some ...llent assistants. But this, the only satisfactory source I know ..., is at present dried up apparently.

Is this not a subject which the P.P.A. ought to firmly take in ... and try to emulate the efficiency of our American friends, who ... so thoroughly look after and properly train their assistants!—... truly,

BELGRAVIA.

THE FIRST TEXT-BOOK OF BROMIDE PRINTING.

To the Editors.

Gentlemen,—When visiting the South Suburban Photographic ...ety recently, a club to which many Blackheath and Greenwich ...bers belong, my friends there fell to talking of the part men of ... district had played in the history of photography, of the early ...facture of bromide paper in the suburb, and of Mr. W. T. ...gan, the local professional—still well-remembered by some—who ... so much towards making bromide paper a commercial success, ... local firm becoming in later years Morgan & Kidd, with works ..., Surrey.

...mide paper of a sort was advertised by a Liverpool firm as ... as 1874, the advertisement appearing in the "B.J. Almanac" ... year, but it did not catch on, in spite of the efforts of Mr. ... Mawdsley to popularise it. Harrison's "History of Photo... ..." states that: "In 1880 Messrs. W. T. Morgan & Co., of ...wich, commenced the manufacture on a large scale, and in a ...phlet written for the firm by John Burgess and published in ..., 1880, it is stated that such paper had been made by them since ..." Harrison also tells us that Morgan's paper was "to be used ...printing by development, after the manner suggested by Abney in the same year (1880)," and this method is given on pages 103 and 160 of the 1880 volume of the "B.J."

Knowing of my collection of old photographic books, I was asked about Morgan's booklet, which was understood to be most rare, and I was sorry to confess that I did not possess it—had, in fact, never seen it. But to-day I have it, thanks to the kindness of a gentleman who knew the writer of it, and who actually printed it.

The booklet, paper covered, and of 6½ x 5 plate size, contains in its 56 pages much that is of interest; it is written in a breezy "take-you-by-the-hand style," and its price was half-a-crown, a sample bromide print being included as a frontispiece.

The title page is not the least interesting of the book's varied contents, for it reads as follows: "The Argentic Gelatino-Bromide Workers' Guide, or How to Produce Perfect Sparkling Negatives in the Shortest Time, with the Least Trouble and the Greatest Certainty: with Instructions for Using the New Argentic Bromide Paper for Rapid Positive Printing; also How to Make Transparencies; Magic Lantern Slides; Ivorytypes (or the Eburneum Process); Enlargements on Opal, Paper and Canvas; besides many Wrinkles of an Old Practitioner, by John Burgess, the Originator of Washed Gelatino-Bromide Emulsion, Pellicle, Dry Plate, etc. Illustrated by Specimens of Instantaneous Photography. Produced by W. T. Morgan & Co.'s New Argentic Gelatino-Bromide Plates and New Method of Development. Published by W. T. Morgan & Co., Hello House, The Circus, Greenwich, S.E. Printed by H. S. Richardson, Greenwich."

In his "Introduction," Mr. Burgess writes: "It is now seven years since I introduced an entirely new process for dry plates. ... and I ventured then to predict that the advantages offered by the new process were so numerous and so great that eventually it must supersede the bath and collodion. My expectations are now in a fair way of being realised." After enlarging upon the advantages of the dry plate, he continues: "It is a great satisfaction to me to announce that in the early days of argentic-gelatino bromide I found a sympathising worker in Mr. W. T. Morgan, of Greenwich, a practical and skilful photographer, doing a high-class trade, and with whom I am now commercially associated—to him, and his manager, Mr. R. L. Kidd, I am indebted for many valuable hints, which immensely enhance the utility of this little book."

The worker is told how to make his own darkroom light by covering the window with two thicknesses of orange-coloured paper, made by staining yellow paper in spirit 4 ozs., aurine 1 oz., and afterwards rubbing it over with boiled oil. After this the reader is told that he can get suitable material for covering a window from a dealer, and that "perhaps the safest way will be to get it there." Pyro-ammonia is recommended as a developer for the plates, and vertical baths and dippers, "some use dishes, but the baths are more convenient." Ferrous oxalate, "a comparatively new developer," is also described, and the instructions for developing the negative are most elaborate.

The booklet is naturally very strong on the advantages of the firm's specialty—bromide paper, which "is destined to play an important part in the production of the positive picture, and to extend the photographer's business to much wider fields of enterprise than have yet been opened to him. He need not be in future the minister of vanity, but may aspire to a much more important place as a promoter of trade and commerce, of art and science. ... A better time has come for our profession, all who are wise will be ready for the flood tide and float joyously on to fortune. The bickering doubters will halt and hesitate till the opportunity has passed, and go puddling all their lives in shallows. Let every photographer learn to make the most of gelatino-bromide, and his lot will be a happier one than of old."

This, and very much more of it written in a similar strain, forms interesting reading to-day when bromide paper is so widely used. The remarks are also of great historical interest for, if I am not mistaken, the booklet was one of the first—if not actually the first—to be written on the advantages and working of bromide paper.

L. TENNANT WOODS.

[Our correspondent tells us that he has ascertained from his informant that the date of publication of the book was 1880. Historically the date is of some importance, as it establishes that of the commercial manufacture of bromide paper by Messrs. Morgan & Kidd. The R.P.S. catalogue queries it as 1890, which is obviously ten years later than the true date.—EDS., B.J.]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. H. S.—For all-round outdoor work, with a half-plate camera, we think 9 inches is the best focal length.

M. W.—The photograph has been eaten by insects in places. This is a more common experience than, perhaps, many people imagine. Spiders will cause this kind of damage to prints, and so will other insects to be found in a house.

H. B.—Providing reasonable care is taken in the manipulation—that is to say, the inscriptions not rubbed—the ordinary waterproof Indian ink, as sold by artists' dealers, and as made by Messrs. Charles M. Higgins and Co., 11, Farringdon Avenue, London, E.C.4, is very suitable for your purpose.

W. S. E.—The photograph evidently suffers from reflection by the semi-mirror like surface of the tablet. Although it may make the light very much weaker, we are afraid the only way to get rid of this is to back up the camera with a big screen of dark material of such size, that when you put your eye as nearly as you can in the position of the lens you cannot see reflections from the tablet. It may be a question of giving several hours' exposure, but we know of no other way of overcoming the difficulty. A panchromatic plate used through a K2 light-filter might be of advantage, but not sufficiently so as to obviate the necessity of erecting a screen behind the camera.

A S.—We do not think that you will do better than to fit four 1,000-c.p. are lamps in the positions indicated by red crosses on your plan (returned). A fifth might be added in case you want to make larger groups. The lamps should be 8 ft. from the floor for standing figures, but should lower to 6 ft. or even less for sitting poses and children. You will note that we have chosen the other side of your studio, as not only will the lamps not interfere with the daylight, but nine sitters out of ten are better looking when the left cheek is turned to the camera. Each lamp should have a thin calico or close muslin diffuser in front and a white reflector behind.

W. H.—The method of ascertaining the effective diameter is as follows:—The lens is fitted to the camera and focussed on a very distant object. For a 10-inch lens the object should be at any rate a mile away. Then, without altering the adjustment of the camera in the slightest, the focussing screen is replaced by a piece of cardboard with a pinhole in the middle of it, and, in the dark room, a small piece of bromide paper is placed in the cap of the lens, and the cap then put on, the bromide paper, of course, facing the lens. If now with the full aperture you burn an inch or so of magnesium ribbon immediately behind the pinhole, you will get a black disc on developing the bromide paper. The diameter of this disc is the effective diameter of the lens, that is, by dividing this diameter into the focal length you get the actual F. No.

H. B.—(1) Most of the cheap enlargement firms use a good, solid pattern of square bellows camera, fitted with a fairly rapid lens, which may be even a portrait lens, or at any rate has an aperture not smaller than about *f*/5.6. (2) This copying work is very commonly done on 3½ by 2½ plates, or in about this size, making several exposures on a larger plate by means of one of the repeating backs, such as the "Multisecto," or similar appliance of Messrs. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.2. (3) It is usual to copy down to 3½ by 2½, or to copy-enlarge direct to this size when working from very small originals. (4) No book on the subject. (5) When reducing, the best plate is one of the rather slow landscape type, or even one of the special "fine grain," such as almost every maker now supplies for copying. These plates are rather slow when copying-enlarging, and in order to keep exposures reasonably short we think you would have to use a faster plate. (6) For the large degree of enlargement, which will be necessary, the negative should be quite thin and soft.

E. S. M.—(1 and 2) We think there is little to choose between a high-power half-watt of, say, 1,000 c.p. and a number of smaller ones amounting to about the same power. In either case, for good diffusion, you would want one thickness of opal glass, although if you use a number of smaller lamps, say, five or six of about 200 c.p., you could very likely obtain sufficient diffusion with ground glass. We think the gas-filled lamps are the better, certainly if the light box is going to be moved up and down, on account of their greater strength, and also because in most patterns the filament is horizontal, whereas with ordinary vacuum lamps the filament usually runs in the worst position for your purpose, namely, vertically. (4) So long as the inside of the lamp house has a matt white coating it does not matter very much what shape it is. Certainly a dome roof would be somewhat better. The chief difficulty in this system of illuminating a negative is ample ventilation of the lamp-house. You want to have it as big as you conveniently can, and make the fullest provision for entry of air below and exit from the upper portion.

P. L.—It is hopeless to attempt a job of this sort if the shop-front itself is in shadow and the opposite side of the road strongly lighted. The conditions require to be reversed, and even then it is often no easy matter to avoid patches of reflection in the window, which look unsightly and effectually hide, in the photograph, the goods which are displayed. Sometimes in undertaking such a job it is worth while to erect a screen of dark material behind the camera so as to cut out opposing buildings. In a busy thoroughfare this can only be done in the very early morning, and often then only by using quite a small stop in the lens in conjunction with a slow plate, and so giving an exposure which is long enough to prevent the passage of people along the pavement from having any effect on the plate. Some prefer for this purpose to use an ordinary slow plate behind a colour filter simply for the purpose of running the exposure into minutes. Where no screen is possible, reflections can sometimes be dodged, even when taking a front view, by placing the camera pointing straight towards the shop front, but a little to the right or left, and making use of ample cross-front movement on a square-bellows camera. This calls for a lens of ample covering power. If the contents of a window are thoroughly well lighted by concealed lamps, as is done now by many expert window-dressers, such jobs can be very successfully tackled at night. A colour-sensitive plate and a long exposure are called for, and, for securing the facia and outside of the shop building, a supplementary lighting from a couple of magnesium torches (each of four or five strands of magnesium ribbon) requires to be used. Sometimes it is possible to arrange to use daylight for the supplementary lighting by doing the work in the very early hours of the morning, and, without moving the camera, waiting for daybreak as a means of illuminating the outside of the building. There is no book on general outdoor work; the little manual, "Commercial Photography," price 1s. 3d., post free from our publishers, deals with some branches

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3222. Vol. LXIX. FRIDAY, FEBRUARY 3, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. Louis Nell describes the making of a vertical pattern of enlarger for use with incandescent gas, and shows, with the aid of several illustrations, how a useful appliance of this kind can be readily constructed at small expense. (P. 63.)

In a leading article some practical hints are given on the making of carbon prints upon rigid supports, such as ivory or ivorine, wood, metal or glass. (P. 62.)

The Rev. H. O. Browne, following an exposition of the general principles of stereoscopic photographic and viewing, proceeds to the formulation of definite rules for the print width of stereoscopic pairs. (P. 64.)

The Lancashire Society of Master Photographers is arranging an interchange series of lighting and posing demonstrations at members' studios, and has taken the step of allowing a member to nominate an assistant as an affiliated member in order that employees in charge of studio work shall share in the benefits of the demonstrations. (P. 68.)

A remarkable optical recommendation in connection with photographic portraiture was recently passed off by a daily newspaper, obviously by an error of ignorance, as the opinion of an expert a portraitist as Mr. C. P. Crowther. (P. 61.)

Correspondence appears on the pros and cons of the September Congress of the P.P.A., and on the causes of inefficiency of photographic assistants. (P. 70.)

At the Croydon Camera Club, Mr. H. P. C. Harper gave the pyro formula used by him in the development of lantern slides. (P. 68.)

The remedy of a farmer's wife for burns from flashlight and a cure for metol poisoning are communicated by a correspondent. (Pp. 69-70.)

An optical device for the photography of the living eye is the subject of a recent patent specification. (P. 66.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article Mr. R. M. Fanstone describes and illustrates a pattern of plate-holder specially suitable for exposure of Paget colour screen-plates in the way of producing firm and even contact between the taking screen and the emulsion surface. (P. 5.)

We give working details of the method of three-colour printing worked out by Mr. J. F. Shepherd, and named "Triadochrome" by him. (P. 8.)

The first drama cinema colour film to be produced by photographic processes has been exhibited as "The Glorious Adventure." The film is by the Prizma process. (P. 8.)

A process of producing colour cinema films, which has recently been patented, is based upon the taking of larger and smaller negatives, positives from which are afterwards combined in the colour film. (P. 6.)

A method of making three-colour prints, devised by Mr. John Lewisohn, of New York, is based on special treatment of a ferro-prussiate print. (P. 7.)

EX CATHEDRA.

Press Photographs. There is a certain significance in the recent announcements that official organisations in France and in Italy are undertaking a photographic news service, and are placing such photographs at the disposal of journalists and newspapers, having need of illustrated matter dealing with these countries. Such a course would hardly be taken if Press photography at the present time maintained a reasonably high standard of accuracy—a standard as high, say, as that applying to the news in the papers. But anybody who turns over the pages of the daily illustrated newspapers and the "news photograph" sections of the ordinary daily Press, realises how far Press photography has fallen below its original mission of reporting the news of the day in photographic pictures. At the present time it is scarcely an exaggeration to say that one-half of the photographs reproduced in the newspapers are not news at all, but manufactured studies or photographs of incidents or people so insignificant as not to be worth the cost of plates, blocks and paper which their publication represents. One has only to think of the difference between the picture dailies now and the "Daily Graphic" of the period before its recent transformation, when it was a legitimate picture newspaper, in order to realise the regrettable change which has taken place. We are not reflecting upon Press photographers who, perforce, must supply what publishers and editors want, but it is futile to shut our eyes to the fact that photographic illustration of the popular Press has fallen to a very low level, and now is a purveyor of genuine news only to a fractional degree.

* * *

Intimacy. We know Mr. C. P. Crowther to be a most accomplished portrait photographer and also the possessor of an inexhaustible flow of engaging talk. The latter is an asset which has its dangers. An example of them is contained in what professes to be the report of an interview with Mr. Crowther published last week in a daily newspaper. It appears that "intimacy" was the subject of conversation. "Intimate photography," Mr. Crowther is represented as having said, "is the most interesting thing at the moment," but all we can learn of this interesting development is that the "intimate" photographer, instead of asking his subject to sit some distance away from the camera, places the latter right up against the sitter's face. This recommendation is given the emphasis of a headline, and it is further stated that "as experimental knowledge of the use of the lens develops in this direction we shall be able to make the camera record as nearly as possible what is seen by the eye." We suggest, on the other hand, that as experimental knowledge of the use of the lens, on the part of the newspaper reporter, develops, it will be ascertained that a lens possesses a focal length. We have no doubt that Mr. Crowther did

say something to his interviewer which optically was not downright nonsense. When the subject passed into questions of psychology, the reporter seems to have been on surer ground. He tells us that when Mr. Crowther is photographing a man, he says, "just talk into the camera to the prettiest woman you know," and the result is good. There we have something which sounds more like a genuine Crowther formula.

* * *

Associate Assistants. We welcome, as an altogether wise and prudent proposition, the move which is announced on the part of the Society of Master Photographers, namely, the admission of (selected) assistants as associate members of the Society. As a report on another column shows, this broadening of the Society's scope has been prompted by a desire for assistants to be present at the interchange demonstrations which are now being arranged among members of the Society. It is a step forward, calculated to benefit all concerned. Are we to assume that what Lancashire thinks to-day will be the programme of similar associations in the near future?

CARBON PRINTING UPON RIGID SUPPORTS.

Apart from the well-known qualities of the carbon process, absolute permanence and variety of colour, there is another very important one which is generally overlooked, and this is its adaptability for producing images upon surfaces which, by reason of their liability to stain or corrode, cannot be coated with the usual solutions or emulsions used upon glass or paper.

The most generally needed application of the carbon process to any other support than paper is in the production of a "photographic basis" to an ivory miniature, but prints upon other supports are sometimes needed, such as miniature reproductions of memorial tablets upon brass, copper, or even marble plaques or medallions or panels of wood for decorative purposes.

This branch of carbon work presents no greater difficulties than the ordinary double transfer process upon paper, and as the prints required are usually very small in size, a first attempt in carbon printing may well take the form of a miniature upon genuine ivory or ivorine.

As full details of the procedure in carbon printing are to be found in every photographic manual, there is no necessity to recapitulate them here, but there are a few points to which attention may be drawn in order to prevent discouraging failures. In the first place, the tissue used should be quite freshly sensitised, in order that there may be no trace of "tint," and that it may be developed at a fairly low temperature to preclude the possibility of sticking to a properly-waxed temporary support. It is desirable, if the tissue be bought in a sensitive condition, that it be used within two or three days of its receipt. Sensitising is, however, such a simple matter, that it is better to do it at home and be independent of the post. All that is required is a five per cent. solution of bichromate of potash, to which a few drops of ammonia have been added, and one or two ferrotype plates with good surfaces, which have been rubbed with a rag moistened with petroleum and then polished until all greasiness has disappeared. After immersion in the sensitiser for from one to three minutes, according to temperature, the tissue is gently, but firmly, squeegeed upon the ferrotype and set aside to dry, care being taken that no very strong light falls upon the back. In a warm room drying will be complete in about three hours and the tissue will come away with a perfectly flat and even surface, free from streaks and unaffected by any gas or coke fumes which may have been present in the room, because the surface has been protected by the ferrotype plate as long as it was moist enough to be injured.

Prints to be transferred to ivory should be very delicate in character; hence, over-printing must be avoided. It is a good plan to print rather lightly and to commence development with water at a temperature of 80 degs. Fahr. This is to avoid washing away the more delicate half-tones. When developed, the prints should be alumed, rinsed and hung up to dry, while the ivory is being prepared for their reception.

In order to secure adherence of the carbon image to the ivory the surface of the latter must be coated with a thin film of insoluble gelatine, which is made and applied as follows:—Half an ounce of gelatine is soaked in water until well swelled, the water is poured off and eight ounces of hot water poured on. This will dissolve the gelatine; to this add 10 grains of chrome alum dissolved in two ounces of hot water, stirring or shaking well meanwhile. This solution should be poured over the ivory as in varnishing a negative, or the ivory may be immersed so that both sides are coated. The ivory is then set on edge, away from dust, until quite dry. When the coating is quite hard, the remainder of the gelatine solution should be poured into a warm dish and brought into a quite thin condition over a gas ring or stove; the print on its flexible support is immersed until limp, and then the ivory is slipped in beneath it and the two lifted out together, brought into contact by a couple of strokes with a squeegee and set aside to dry. When dry, if the paper does not fall off, a gentle pull will detach it, and the carbon will be left firmly attached to the ivory. The picture may now be handed to the artist, who will probably prepare it for colouring by rubbing the surface down with pumice powder until the image is faint enough for his purpose. If it is to be tinted only after the fashion of a paper print, the rubbing down may be omitted.

It will be noted that when purchased one side of the ivory is evenly ground, and the other usually shows lines or saw marks. It is advisable to mark the latter with a pencil cross in one corner, to avoid mistakes in coating and transferring, as it is not easy to distinguish the sides when they are wet.

Ivorine or celluloid is frequently used as a substitute for the more expensive ivory for cheap work; it is treated in exactly the same way as described for ivory. Brass or silver plates must be freshly polished and quite free from grease. A final polish with alcohol and whiting will ensure this, but care must be taken that all traces of whiting are removed from the back and edges, or they may get mixed with the substratum. Wood should have the grain filled with a good varnish, such as white copal, which, when hard, is rubbed down with pumice powder and water before coating with the substratum.

Prints may be developed upon ground opal glass without other preparation, or they may be transferred as already described. If they are to be coloured it will be found advantageous to use the gelatine substratum, as this gives a continuous coating over the high-lights, making it easier to get an even wash than upon the raw surface of the opal. Glass must be coated with the gelatine substratum, or there is danger of the film scaling off. Bichromated gelatine is often used for clear glass, but the chrome-alum solution is equally effective.

In case a failure has been made in transferring, the print should be soaked in water until soft, and then as much as possible removed with a stiff nail brush; a little damp pumice powder applied with the finger will remove any remaining traces of the coating and leave the support ready to start *de novo*.

A HOME-MADE VERTICAL ENLARGER FOR INCANDESCENT GAS.

Of recent years much attention has been devoted to the vertical form of enlarger, but with one exception all patterns that I have seen were fitted for electric light. These notes may interest photographers with no electric light and but little space at their disposal and who can afford only a moderate outlay.

The apparatus illustrated is the outcome of a suggestion I made several years ago to a friend whose mastery of tools is that of a skilled cabinet maker. The original model gave good results, but practical work entailed the gradual addition of many improvements, so that the apparatus now leaves little to be desired.

There is a light-box, *a*; a removable box, *b*, for condenser and negative carrier; a camera-fitting, *c*, to which I can instantly attach an old camera, 16; an easel, *d*, and two uprights, *e*, to which the light-box is screwed, and on which the easel slides.

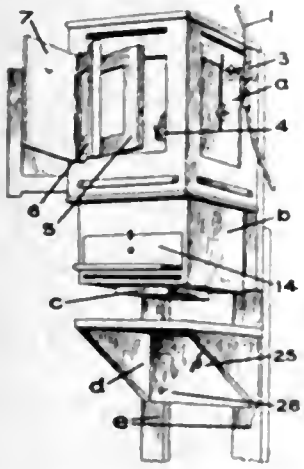

Fig. 1.—Light-fittings, hinged front windows and reflector, and easel raised when not in use.

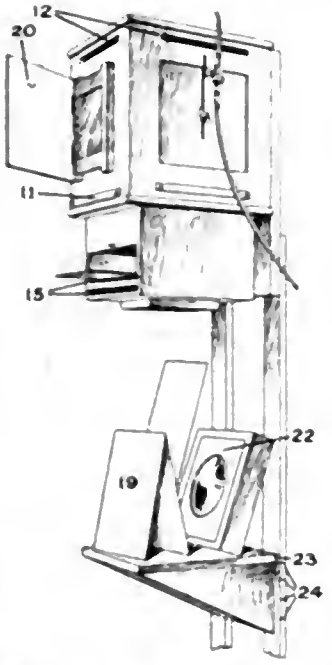

Fig. 2.—Condenser drawer, ventilation slots, paper-holder, and registering indicator for easel.

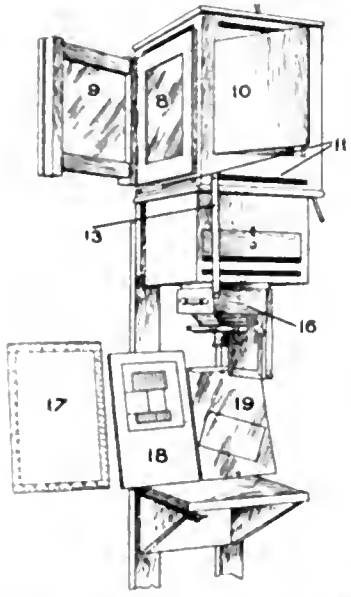

Fig. 3.—Slot for plain or ground glass, negative carrier (with inner carrier for stereo negative 45 x 107 mm.), postcard in paper-holder, and scaled composing card.

The asbestos-lined light-box has a fitting, 3, for a central bijou inverted mantle, 4; this fitting slides vertically, and can be clamped at any point. A length of metal tubing, 1, connects with the ordinary gas bracket. The front has a hinged door, 5, with a yellow safe-light. An outer frame, 6, hinged to this door carries a red safe-light. There is also a hinged white reflector, 7 and 10, throwing the light on to the developing stance. A screw-eye, 20, on the reflector enables a watch to be hung in the light (yellow or red), the seconds hand being quite visible from a distance. On the side of the box opposite the burner fitting there is a large yellow window, 8, with a hinged outer red safe-light, 9. Instant change of colour is therefore a feature. Green can be substituted for red in a few moments. Ventilation slots of ample size (11, 12 and others not shown) prevent heating. The lower front opening is not permanently trapped, there being a cover (13, shown open) permitting the easy insertion or removal of a sheet of plain or ground glass (I grind mine with knife powder). This glass catches droppings from the mantle and—in conjunction with the inflow of cold air just above it—ensures a cool condenser. The condenser keeps cucumber cool; it cannot crack and does not dew. The 5-in. condenser lenses are fitted in a drawer, 14 and 22, and can be instantly cleaned. They cover the useful portion of a quarter-plate (for enlargements to half-plate and upwards). There are two shelves, 15, for the negative carrier, 18, which takes quarter-plates or any smaller size either "horizontally" or "vertically," so as always to show a right-way-up image on the easel. The lower shelf is for the smaller negatives. Any portion of a half-plate within a 5-in. circle may be enlarged as well. Any part of a negative can be centred instantly on the easel. The easel measures 10 by 12 in. A drawing-board laid on it could take larger sheets of paper if required. To facilitate composing I use a white card, 17, scaled in inches and centimetres. The easel is clamped to its sliding base by a wing-nut, 25, and prevented from swinging by a pin, 26 (mine is a sardine-tin key), passing through easel and base. By drawing out the pin the easel can be swung. For non-scientific work this one movement suffices to correct distortion due to tilting. The easel also serves as a printing table for contact bromides and slides.

With this apparatus and a *f*/6 stigmatic of 4½ in. focus I can reduce to half diameter, copy to same size and enlarge up to 7½ diameters. By removing the easel and placing the paper on the floor, or on one or more books placed on the floor, a still greater degree of enlargement is attained.

Focussing is done on a piece of paper the same size as the desired print. For holding this or the bromide paper I made a holder, 19, of a piece of millboard to which is hinged a slightly smaller sheet of glass. Two wooden studs are stuck on the glass; one facilitates opening the holder, while both together enable the holder to be easily moved on the easel, thus placing the paper in position with the utmost nicety and expedition.

A minor feature very conducive to comfort in working

deserves mention. A round-headed screw, 23, is inserted at the side of the easel, and other screws, 24, are placed at the side of the upright at points indicating enlargements of 1 (same size), 1.7, 2, 2½, 3, 3½, 4, 5, 6, 7 and 7½ diameters. By laying the ball of the finger on the easel screw the tip will touch those on the upright when the easel is shifted. Any easel position can be obtained by touch alone. For use when the negative is placed on the upper shelf there is a second easel screw below the first, the distance between them being that between the shelves.

The advantage of this apparatus are:—No permanent occupation of floor-space; immediate readiness for use; no heating of condenser; less danger of vibration than with a horizontal model sprawling across the room; quick change from one degree of enlargement to another; instant centreing of any part of the image; rapid repeats of identical prints; a very brightly-lit "dark" room, with instant change from yellow to red (or green) for negative work.

My friend was so delighted with our results that he has built a number of these enlargers, one for himself and the remainder for other enthusiasts. These models are much nattier, have three windows instead of two, a rack-and-pinion movement for the light, a lens-board and bellows with quick slide and micrometer focussing, and uprights hinged so as to pack into a small space. The cost, complete except for lens, gas tubing and paper-holder, works out at about £8.

Vertical enlargers built for electric light cannot well be used for gas. This apparatus can be adapted for electric light without difficulty. Should electricity become available I shall discard the condenser and fit a top light—yellow and red (or green)—so as to get reflected light from the ceiling in addition to what is now available. LOUIS NELL.

THE PRACTICAL STEREO PHOTOGRAPHY OF SMALL OBJECTS.

(*Continued from page* 51.)

THE examples just given will probably serve to show that the task of photographing small objects is simplified, rather than made more difficult, by the adoption of this method. The erection of the verticals at a measured distance apart fulfils the same purpose as the drawing of a line of measured length, which is usually the way recommended for facilitating exact reproduction to scale. Further, the photographer can always supply himself with the exact *object distance* and *camera extension* whether he uses the correct lens or not, and the tedious necessity of repeated experimental focussing is thus entirely avoided. We have yet, however, to discover the working formulæ that will make him master of the process.

The problem of stereo photography is essentially three dimensional, since the image is to have width, height and depth, but there is only one dimension with which we need now concern ourselves—namely, the *width*, measured in inches, of the image, the object, the negative, and the print. The last two we hope to make identical. The dominant importance of width will appear as we go on. Each plane of the image and of the object will also have its own *distance;* but we will choose one corresponding plane in each, which we will call *image distance* and *object distance* respectively, upon which to build our formulæ. By carrying over two simple working principles from the previous investigation the other dimensions and distances will be correctly rendered without further attention on our part.

The photographer sets the problem and supplies particulars of what he wishes to be done; the stereoscope determines the conditions of success, and lays down certain limitations; the camera lens, like an obedient servant, merely takes its orders and obeys them. Let us formulate in due sequence the data we get from these three sources; we can then set about unifying them and reducing them to their simplest form.

The photographer wishes to produce images at a variable distance x, and on a variable scale n with regard to the original objects. Therefore, we have as our starting points :—

Image distance $= x$. *Image width* $= n$ times *object width*,

$$\text{or } \frac{\textit{image width}}{\textit{object width}} = n \quad \text{(Ratio 1)}.$$

This will be a convenient place to take note of the two working principles just referred to. They are (1) that if the image is to be n times the object and at a distance x, then *object distance*—the distance of the object from the camera lens—must be $\frac{x}{n}$; and (2) that *lens separation*—the separation of the camera lenses when taking the left and right negatives—must be $\frac{S}{n}$ where S is the normal eye separation, or inter-pupillary distance. With the introduction of this quantity S, which will be dealt with in its proper place, we depart from the possibility of strict mathematical precision, but not from that practical accuracy of result which is all that we require.

The above two principles may be set down in another form in which they may perhaps more readily commend themselves to our judgment :—

When *image width* = n times *object width*,
then *image distance* = n times *object distance*,

and separation of viewing points, i.e., *eye separation* } = n times { separation of taking points, i.e., *lens separation*.

Theory here becomes categorical, and declares this to be the only way in which correct perspective, correct size and correct distance can be secured in the image.

We now turn to the stereoscope to see upon what conditions it is willing to accept, and how far it is able to solve correctly the problem proposed to it by the photographer.

When a photograph is examined through a small magnifying glass, such as would be used in a stereoscope, there is, in spite of the obvious change of size, a strong inclination to imagine that we are still looking at the photograph itself. (It may be noted that this obsession, due to our previous knowledge of the actual nature, size and position of the object we are examining—knowledge which has been verified by touch as well as by sight—is one of the gravest obstacles to the realisation of the stereo image; it plainly indicates how imperative is the necessity that the image should be separated out from all other sense impressions, and given an existence of its own if it is to produce its full effect.) But if the lens is moved to left or right in front of the eye, the view is seen to move sharply in the other direction. We are therefore no longer looking at the photograph but at its image projected back to a greater distance. It is a fundamental principle of optics that the image of any point thus viewed through a lens lies on the right line connecting the point with the lens centre, and remains in a fixed position as long as the point and the lens remain fixed. Again, if the lens is held steady, and the eye is moved from side to side behind it, the image is seen to pass across the field of view in the same direction as the eye, just as stationary objects outside a window seem to respond to the movements of an observer within: there is no real movement of the image. This fact, that the position of the image in space depends upon the relative position of the lens and the photograph, and is independent of that of the eyes, is very convenient for our present purpose.

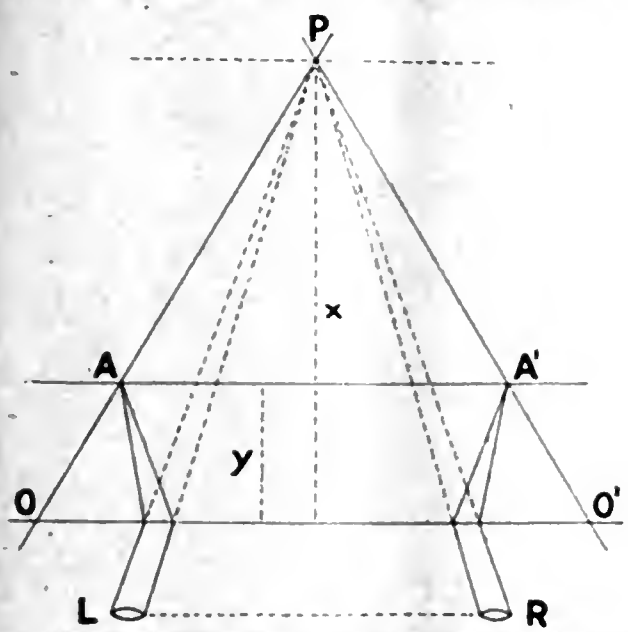
An elementary optical formula tells us that if the image of a photographic print is to be projected to a distance x from the centre of a lens of focal length f, the print must be placed at a distance y from the lens centre which is given by the equation, $\frac{1}{f} = \frac{1}{y} - \frac{1}{x}$; and that the size or *width* of the photo-

graph will be to that of the image as y to x. From the first of these expressions we can easily find that $y = \frac{fx}{x+f}$, and that $\frac{y}{x} = \frac{f}{x+f}$.

We have therefore: $\frac{\text{print width}}{\text{image width}} = \frac{y}{x} = \frac{f}{x+f}$ (Ratio 2).

The troublesome variable y can thus be got rid of from the working formulæ.

Let us suppose, Fig. 1, that a stereo print has been successfully prepared and placed in position in a stereoscope, of which O and O^1 are the lens centres. For the sake of clearness the angles and displacements in the figure are greatly exaggerated, and the lenses are only indicated by their centres. The distance OO^1 then represents the separation of the lenses, and the line through O and O^1 the plane of the stereoscope. Let A be a point in the left print, and A^1 the same point in the right print—representing, say, some prominent marking in a butterfly's wing. The line through A and A^1 will then represent the plane of the prints, and the distance AA^1 will be the distance between corresponding points in the two prints. The image of A will lie somewhere along the line OA, and the image of A^1 somewhere along the line O^1A^1. The condition of success is that



L, left eye. R right eye. O and O¹, centres of left and right stereoscope lenses (lenses not shown). A and A¹, corresponding points in left and right stereo prints. P, point of image. Width of prints A A¹ is determined by O O¹ and x. Perspective of prints is determined by L R, i.e., the prints must be such that when viewed from L and R they give correct perspective.

the image, in each case, should coincide with the meeting point P of these two lines. P will then be the position of this point of the image, no matter where the eyes, L and R, are held behind O and O^1. The figure makes it plain that, although the light in each case starts from the points A and A^1, it *really* enters the eyes as from the point P, and that the eyes are focussed and converged upon this point as in nature. The point P must also be at the vertical distance x from OO^1, this being the chosen distance at which the image is to be situated. A line through P parallel to OO^1 will then represent the plane of *image distance*. Finally, the whole image must be correct in size and perspective, not only for points lying in this particular plane, but for those in all other planes, whether in front of or behind it.

The separation AA^1 is constant for all points that are to be projected to the distance x. It is clear, therefore, that if the prints as trimmed for mounting are wider than AA^1 they cannot be properly placed in position. Either the inner edge of one print will overlap the other and cover it up, or if they are placed side by side the distance AA^1 will be increased and the whole of the resultant image displaced. The fact that the prints must not extend to a greater width at their outer or free edges may appear puzzling, but it is a rule well known to stereo workers that nothing must appear at the outer edge of either print which does not appear in the corresponding inner edge of the other. The distance AA^1, therefore, represents the full *print width* available in any case, and it is of the greatest importance that we should know its exact value, that we should be able to obtain it without difficulty, and that it should be automatically recorded on the negatives at the time of taking. The mere mechanical trimming of the prints to size by no means makes it certain that the contents of the prints will be correct or that corresponding points will be properly spaced.

It is easily seen from the figure that $\frac{AA^1}{OO^1} = \frac{x-y}{x} = 1 - \frac{y}{x}$.

Substituting the value of $\frac{y}{x}$ given above, and simplifying, we have:—

(a) *Print width* $(AA^1) = OO^1 \frac{x}{x+f}$.

We saw above, Ratio 2, that $\frac{\text{print width}}{\text{image width}} = \frac{f}{x+f}$. Substituting in this expression the value of *print width* just found, and simplifying, we have:—

(b) *Image width* $= OO^1 \frac{x}{f}$.

Since *image width* n times *object width*, we have, from (b):—

(c) *Object width* $= OO^1 \frac{x}{nf}$.

The expression (b) shows that the possible width of the image varies directly with x, and inversely with f. The stereoscope chosen should therefore have lenses short enough to give images of reasonable width for small values of x, but not so short as to increase the worker's difficulty in taking the negatives and securing precision in his results. The separation OO^1 of the stereoscope lenses also directly controls the width of the image, but as it is necessary that the eyes should be more or less centrally situated behind the lenses so that they may have an uninterrupted view, this separation should be made small. These and other considerations led the writer, for the practical purposes of this article, tentatively to recommend the stereoscope already described, having 4-in. lenses, with a separation of 2.5 in. The angle of view of 36 deg. from side to side given by this stereoscope seems quite as wide as is desirable from either the technical or artistic standpoint.

H. C. Browne.

(To be continued.)

Photographs of "Horrible Examples."—Groups of photographers were sent out during a recent temperance celebration in Tokyo to take pictures of drunken men in the streets and parks. This measure was taken by the National Temperance Association in the hope of disgusting the people with their actions while under the influence of liquor.

Death of Sir W. H. Christie.—Sir William Henry Mahoney Christie, who was Astronomer Royal for 30 years, retiring in 1910, died at sea, aged 77. He developed a passion for astronomy when a boy, and in 1831 was appointed Astronomer Royal. During the 30 years which followed he brought Greenwich Observatory to a fine level of efficiency. Under his direction and with the aid of the vastly improved instruments which he obtained for the observatory great progress was made in the work of photographing the sun and the stars.

Criminals as Cinematographers.—In the early days of our art, it was said that photography was a legitimate profession for those who failed the most miserably in other callings, but a noted American detective goes a step farther. The "Daily Chronicle" says:—"One of the greatest detectives of modern times—George S. Dougherty is staying at the Savoy Hotel. Dougherty, formerly a deputy commissioner of the New York police, and a member of the famous Pinkerton detective force, is in business in New York, and has been travelling Europe to investigate varying systems, and incidentally to keep in touch with the big criminals of the world. Friend of criminals who desire to give up the life of crime, Dr. Dougherty has put many of them into positions where they have made good. 'The criminal,' he says, 'is generally the man or woman who must have a life of excitement. It is no good putting them to drive a horse and van. I have found in several cases that work in connection with cinematography supplies the need, and they go straight in it.'"

FORTHCOMING EXHIBITIONS.

January 21 to February 4.—Partick Camera Club. Particulars from the Hon. Secretary, James Whyte, 51a, Peel Street, Partick, Glasgow.

February 7 to 11.—Sheffield Photographic Society. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield.

February 11 to 25.—Scottish Photographic Salon. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Latest dates, entry forms, February 4; exhibits, February 9. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Latest dates: Entry forms, February 15; exhibits, February 23. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 26.—Welsh Salon of Photography. Latest date for entries, March 9. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications, January 16 to 21 :—

COLOUR PHOTOGRAPHY.—No. 1,319. Photography in two colours. O. Pfenninger.

REPRODUCTION PROCESS.—No. 1,562. Production or reproduction of a three-dimensional figure. H. M. Edmunds.

DRAWINGS FROM NEGATIVES.—No. 1,809. Method of making pencil drawings from photographic negatives. W. H. Jones.

PHOTOGRAPHING SOUNDS.—No. 1,574. Photographic sound-recording and light telephony. H. G. Matthews.

COLOUR CINEMATOGRAPHY.—No. 1,590. Colour cinematography. R. O. Percy.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY.—No. 172,714 (Sept. 8, 1920). The invention consists in a method of making colour cinematograph films in which a set of full-sized images is produced on the negative film, with small-sized interposed images; from which negative film a positive film is produced by superposing successively the said images, brought to the same dimensions, and suitably colouring the different positive images.—Zoechrome, Ltd., 146, Bishopsgate, London, E.C., and Thomas Albert Mills, 72, Manor Street, Clapham, London, S.W. (Particulars of the process are given on another page in the "Colour Photography" Supplement.)

PHOTOGRAPHY OF THE LIVING EYE.—No. 173,439 (January 17, 1921.) A small reflector is formed in or carried by a transparent body, such, for example, as a glass disc or lens, which reflector will reflect a beam of light from the sun or from an artificial light into the eye, and will allow the image of the eye to pass around

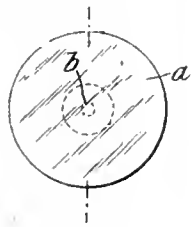


Fig. 1.

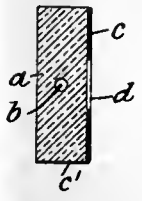

Fig. 2.

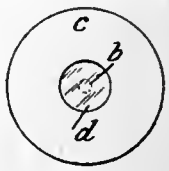

Fig. 3.

its exterior through the transparent body to the eye of an observer or into a photographic camera in front of which it may be fitted.

The reflector may consist of a bubble or cavity in a piece of plain glass, the bubble acting as a reflector and the plain glass surrounding the bubble allowing the image of the eye to pass through it around the exterior of the bubble into the camera, or to the observer's eye.

Instead of employing a bubble in a piece of solid glass two pieces of glass may be cemented together, each piece having a semi-spherical cavity formed therein. These two pieces are cemented with the two cavities facing each other. The two cavities may be employed to enclose a globule of mercury thereby rendering the convex surface which is towards the eye a better reflector.

The single piece of glass, or the two cemented pieces, may have plane incident and emergent faces, or they may be ground to form a suitable lens to co-operate in obtaining a clear image upon a photographic film or plate.

The transparent body is preferably blackened on one face to form a mask around the reflector, but leaving sufficient clear space around the latter for the rays to pass from the eye to the observer or into the camera.

Figs. 1, 2 and 3 show in front elevation, section and rear elevation, respectively, a construction of transparent body carrying or formed with a small reflector. Fig. 4 is a diagrammatic

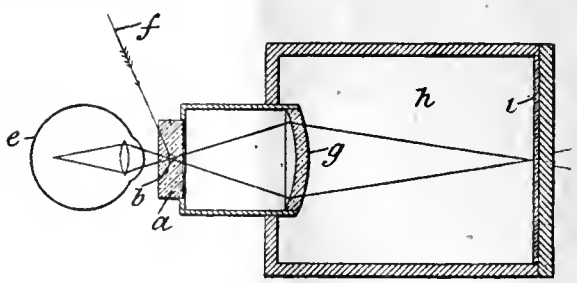

Fig. 4.

view illustrating the use of the device for obtaining a photograph of the interior of the eye.

In figs. 1 to 3 the transparent body *a* consists of a disc of glass with plane incident and emergent surfaces, having a small bubble *b* formed in the interior thereof.

Fig. 4 shows the apparatus used for obtaining a photograph of the interior of an eye *e*. Here the device is suitably mounted in front of the lens *g* of a camera *h*, and the interior of the eye being illuminated by the beam of light *f* reflected into it by the bubble or reflector *b*, the image of the eye passes to the lens *g* of the camera around the exterior of the reflector or bubble, so that an image of the interior of the eye will be formed on the sensitive plate or surface *i*.—Isaac Taylor, 4, South Terrace, Cork.

New Books.

AGENDA LUMIÈRE-JOUGLA.—The collection of tables, formulæ, and working instructions in the photographic processes, which is issued each year by MM. Lumière's firm, renders a service to French photographers somewhat similar to that afforded to those in the English-speaking countries by the "B.J. Almanac." It contains tables of weights and measures, solubilities, chemical equivalents, optical and exposure tables, and, within the space of about fifty pages, a little text-book on the practical working of the Autochrome process. Formulæ for developers, fixers and other baths for the making of negatives and prints by the various processes occupy two other large sections, and in the later part are particulars of the plates, papers and chemical preparations manufactured by MM. Lumière and Jougla. Altogether there are few books of 500 pages in which so much practical information is given in so small a space. The contents are made readily accessible by the provision at the end of the volume of both a table of contents and an alphabetical index. The book is published for MM. Lumière by MM. Gauthier-Villars, 55, Quai des Grands Augustins, Paris, at the small price of 3 francs.

THE "KINEMATOGRAPH YEAR BOOK," 1922.—The annual publication of our contemporary the "Kinematograph Weekly" comes to us in its ninth issue as a volume of over 500 pages, containing a most complete record of the various branches of the cinematograph industry. The "Year Book" is concerned chiefly with the production and renting of the films which are shown at the picture theatres, and contains copious particulars relating to these staple branches of the industry. For example, it gives a list of the films shown to the trade in 1921, arranged both in alphabetical order of film title and chronologically. Its list of films released runs from December, 1920, to December, 1921. In addition to including particulars of the trade associations connected with the industry, it contains a directory of firms of all descriptions interested in the trade, and also a list of the cinema theatres throughout the country, with particulars of their changes of programme, prices of admission, and description of electric supply. Another alphabetical section is a "Who's Who" of personages in the producing and renting trades. Technical and legal matters are not omitted from this compilation. Mr. Colin Bennett reviews technical progress during the past year, and adds some photographic and electrical formulæ of chief interest to the film printer or exhibitor. The "Kinematograph Year Book" is published from 93, Long Acre, London, W.C.2, price 5s.

New Apparatus.

THE C. R. LIGHT-PROOF AND AIR-TIGHT DISH COVER.—Mr. C. R. Rathbone, IIa, Sheep Street, Northampton, sends us a very novel form of cover for developing dishes in the shape of a wooden frame, or rather a shallow tray, the whole interior of which is lined by some resilient packing covered by thin rubber sheeting. This appliance, when laid on a developing dish with the rubber sheeting in contact with the rim of the latter, thus forms a light-tight and air-tight seal. Mr. Rathbone tells us, and we can quite believe it, that a dish protected by this cover may even be carried out into the daylight without harm, as regards fogging, to a plate in process of development therein. The cover has been designed by Mr. Rathbone as an aid in his own work of Press photography, and has been found of particular value in permitting other work being done by full illumination in the dark-room whilst plates were at the same time being developed. In similar fashion the cover has been found of service when making bromide prints by an exposed light in the dark-room. The cover is made in two stock sizes, one 15 x 12 inches for 9 x 7 and smaller dishes, price 8s. 6d., post free; the other 18 x 15 inches for 12 x 10 and smaller dishes, price 11s., post free.

X-RAYS HERO HONOURED.—One of the pioneers and first martyrs of X-rays, Dr. J. Hall-Edwards, of Birmingham, has been awarded a medallion and an annuity of £100 by the Carnegie Hero Fund Trustees.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, FEBRUARY 6.

Birmingham Phot. Art Club. "Carbro." N. G. Breeze.
Bradford Photographic Society. "Photography—Its Importance and Power."
Dewsbury P.S. "Amateur Photographer" Prize Slides.
Forest Hill P.S. Lantern Lecturettes by Members.
Kidderminster P.S. "Bromoil Transfer Process." Lord Hampton.
Leeds C.C. "Whitby, the Photographer's Paradise." J. Marston.
Southampton C.C. "Touraine." W. R. Kay.
South London P.S. "Screen Plate Colour Photography." H. A. Siggers.
Wallasey A.P.S. "How a Reflex Camera is Made." W. Butcher and Sons, Ltd.
Walthamstow and Dist. P.S. "Affiliation Portfolio." F. Judge.

TUESDAY, FEBRUARY 7.

R.P.S. "The Application of Flashlight Photography to the Study of Natural History Subjects." Oswald J. Wilkinson.
Belfast C.P.A. Camera Club. "Lantern Slide Making." D. J. Hogg, H.A.
Birmingham Phot. Soc. "A 400-Miles Walk in Dolomite Tyrol." James Shaw.
Bournemouth C.C. Instructional Evening for Beginners. J. Thomas.
Cambridge and Dist. Phot. Club. Demonstration of the Paget Process of Colour Photography. C. B. Coulson.
Exeter C.C. "Life in the Sea." F. R. Rowley, F.R.M.S.
Hackney P.S. "A Talk on London Landscapes." A. E. Farrants.
Leeds P.S. "Holiday amongst Birds." R. Chislett.
Morley P.S. Whist Drive.
Nelson P.S. Whist Drive and Dance.
Rotherham P.S. "Mont St. Michel." W. A. Barron.
Stalybridge P.S. "Old Processes and New Methods." W. F. Slater, of Messrs. Kodak, Ltd.
South Glasgow C.C. "The Soul's Expression in Photography." Dan Dunlop.
South Shields P.S. "Developers and Developing." J. R. Johnston.
Tyneside P.S. "K-Screen Photography." A. C. Collinson.

WEDNESDAY, FEBRUARY 8.

Accrington C.C. "Lantern Slide Making with Ilford Lantern Plates." A. Brooker.
Birkenhead Phot. Assoc. "Old Processes and New Methods." F. W. Slater.
Borough Polytechnic P.S. "The Way of the Lovely Sky." A. G. Buckham.
Catford C.C. "Psychic Photography."
Croydon Camera Club. Annual General Meeting.
Dennistoun A.P.A. "Portraiture." R. Crerar.
Ilford Phot. Soc. "Carbro." A. C. Braham.
Partick C.C. Members' Lecturette Night.
Photo Micrographic Soc. "Typical Section of Rock Forming Minerals." Prof. W. T. Gordon.
Rochdale Amat. P.S. Photographic Chat.
South Suburban P.S. Members' Lantern Slide Evening.
South Glasgow C.C. Lantern Slides."

THURSDAY, FEBRUARY 9.

Camera Club. "Deep Sea Life in the Atlantic." Prof. Johann Hjort, F.R.S.
Gateshead C.C. "Carbro." Dordan Pyke.
Hammersmith Hampshire House P.S. "English Fishing Towns and Villages." A. J. Linford.
Letchworth Camera Club. Open Night.
North Middlesex P.S. "Development." W. M. Rond.
Optical Society. Annual General Meeting.
South Glasgow Camera Club. Whist Drive.
Wimbledon and Dist. C.C. Bromoil Demonstration.

FRIDAY, FEBRUARY 10.

Glasgow and W. of Scot. A.P.A. Members' Whist Drive.
Wombwell P.S. "Across" H. Merrill.

SATURDAY, FEBRUARY 11.

Glasgow and W. of Scot. A.P.A. "Pompeii." J. Mac. F.G.S.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held [illegible] January 31, the president, Dr. C. H. Bothman in the [illegible]

Mr. Herbert H[illegible] delivered a lantern lecture on "Our Old Village Church Story." Mr. Wrench dealt particularly with [illegible] astical features of the minor churches and chapels, pointing out

many examples of interest to be found in churches in different parts of the country.

On the proposition of the chairman, a hearty vote of thanks was accorded to the lecturer.

SOCIETY OF MASTER PHOTOGRAPHERS.

The Society held a very successful meeting by kind invitation of Mr. N. S. Kay at his studios in Manchester on January 25.

There was a very large attendance of members, different sections in the Lancashire area being well represented. Mr. N. S. Kay welcomed the members to his studio, and stated he had no desire to set himself up as a superior person, but what he was going to shew them with regard to posing and lighting would, he hoped, help them to learn something from him as to the methods that he adopted. At the same time he desired it to be distinctly understood that he was not above learning from anyone else, and should any member during the demonstration desire to suggest anything to him, he would be very pleased to receive all the assistance possible.

Mr. Kay then proceeded to give his demonstration on posing and lighting. The lady who acted as the model proved herself very capable of filling the part, and during the demonstration, which lasted over two hours, Mr. Arthur Winter, the President of the Society, Mr. Percy Guttenberg, and other members gave demonstrations.

During the evening Mr. Lawrence, of Messrs. Kodak, demonstrated the advantages of flat films, and all the exposures made during the evening were made on the Eastman Portrait Films. Mr. Lawrence was assisted in his demenstration by four of his colleagues, and Messrs. Kodak did everything possible in order to make the evening a profitable one to all professional photographers.

At the conclusion of the demonstration a very hearty vote of thanks was proposed to the lady who acted as the model, and the President, Mr. Arthur Winter, asked the members to express to Mr. N. S. Kay their appreciation for his kindness in a true Lancashire fashion.

Mr. Gresswell proposed a vote of thanks to the President, and in doing so stated that the members were indebted to him for the arrangements that had been made that evening. This was the first of the series of interesting events which the President had arranged, and he assured the members that Mr. Winter was allowing nothing to hinder him from making his year of office one of interest and benefit to the whole of the members.

The President, in responding, thanked the members for the support they had given him that evening, and asked those present who had not yet paid their subscriptions for the current year to do so, so as to save the trouble and expense of the treasurer sending them further notices.

The Committee had recommended that a new rule should be introduced permitting members to nominate one of their assistants as affiliated member, so that the assistant would be permitted to attend such demenstrations. He asked the members to vote upon this recommendation, and being put to the meeting it was carried unanimously.

Mr. Percy Guttenberg has kindly placed his studios at the disposal of the Society for their next demonstration, and this will be held early in March, and each subscribing member will be furnished with full particulars in due course.

CROYDON CAMERA CLUB.

Mr. H. P. C. Harpur gave one of his unique expositions on "Transparencies and Lantern-slide Making," a not altogether vanished attack of lumbago stiffening his neck towards his audience.

First came a uric-acid comparison between the combined technician and artist (so well illustrated by the lecturer) and those deleful people who filled eveninga with abstract papers on optics and other scientific subjects; these who read from manuscript and departed without the expenditure of a scrap of mental effort. "Attaché-case merchants," scornfully said Mr. Harpur.

He then brought forward an apparatus resembling a guillotine, whose blade descended in steps, but refrained from describing its application. A more "glorified" and complicated model followed, of which a full description was given in loving terms. It afforded strip exposures behind a negative capable of being turned any way, the contrivance being guaranteed light-tight before and after exposure. He, the lecturer, had been round the appliance with a lighted match and could swear to the accuracy of this statement. It appeared well adapted for the purpose, and more convenient than the strip of card usually used by less ingenious mortals.

By its aid a transparency was exposed in strips, and when the best exposure was found it was repeated for the whole plate. When developing it he imparted the somewhat remarkable new that for fear of oxidation he never washed. Also for desperate cases it was advisable to filter the hypo solution.

Finding the right exposure in the same way for a lantern plate a capital slide was secured of a first-class sepia tone. To do Mr Harpur bare justice it must be said that he invariably obtains most pleasing shades of sepia, and his somewhat monotonous formula is as follows:—

A.—Ammonium bromide	1 dr.
Water to	10 drs.
B.—Ammonium carbonate	1 dr.
Water to	10 drs.
C.—Ammonia, .880	1 dr.
Water to	10 drs.

Dissolve two grains tabloid pyro in about half an ounce of water; take 40 minims each of A and B; add 21 minims* of C, and make up to 11 drs.

An acid fixing bath was to be avoided as it injured the tone. "The same remark applies to sepia bromides," confirmed Mr. Wadham. "I am not lecturing on bromide prints, Sir," fiercely lumbagoed Mr. Harpur. Mr. Sellors here gently pointed out that the interruption was by way of support, and not opposition. "I require no support," snapped Mr. Harpur, defiantly throwing back his head and catching a nasty rick of the enemy in consequence.

The demonstration closed with a lantern-show of the (normally amiable) lecturer's slides, and they certainly were "top-hole" in all respects. Having regard to his indisposition the discussion was of a comparatively kindly nature, even the miserable "attaché-case merchants" forbearing. Mr. Vivian Jobling said that mindful of present high prices, trial exposures had been made on gaslight papers of Wellington's as a guide to correct exposures on their gaslight lantern-plates. Once the key ratio was found the method worked well. There was no reason why any bromide paper should not be used with any lantern-plate once such ratio was ascertained. A most hearty vote of thanks was accorded the lecturer lumbago and all, for an instructive and highly amusing evening.

Commercial & Legal Intelligence.

NEW COMPANIES.

Electric Printers and Designers Equipment, Ltd.—This private company was registered on January 20, with a capital of £500 in £1 shares. Objects: To take over the business of an electrical photo copier, designer and draughtsman carried on by F. J. Morgan at 30, Wind Street, Swansea, as the "Electric Blue Printing Co." The first directors are: F. J. Morgan, Ll Breos, Mayals, Swansea, mechanical engineer; R. N. Perkins, 18 Eaton Crescent, Swansea, mechanical engineer; T. A. Goska "Skeena," Park Drive, Swansea, mechanical engineer. Qualification £25. Registered Office: 30, Wind Street, Swansea.

Sunbeam Tours, Ltd.—This private company was registered on January 24, with a capital of £2.000 in £1 shares. Objects: To acquire the interests of H. Cox in the Sunbeam Tours, includir all patents, royalties, stock-in-trade, book and other debts, an trade marks, and to carry on the business of photographer publishers of photographic appliances, manufacturers of sunscope stereoscopes, and other optical instruments and lantern slides, et

* It was stated that the odd 1 minim is most important. Fatuous ide of "attaché-case merchants" as to the strength of ammonia solutio varying in use should not be allowed to influence the mind.

The first directors are: W. Richards, "Shrublands," Hersham, Walton-on-Thames; G. H. Clarke, 2, Southgate, Sleaford, Lincs.; H. Cox, 18, Clifton Road, Weston-super-Mare (managing director), all permanent, subject to holding 250, 250 and 750 shares respectively. Registered Office: 69-70, Fleetwood House, High Holborn, W.C.1.

ORION PUBLICITY SERVICE, LTD.—This private company was registered on January 24, with a capital of £500 in £1 shares. Objects: To take over the business of advertising agents and consultants, designers, photographers, printers and publishers, carried on by W. B. Price, A. F. Beard and A. H. Lodge, at Stockport, Cheshire, as the "Orion Publicity Service." The permanent directors are: W. B. Price, 62, Vicarage Road, Stockport, advertising agent; A. F. Beard, 6, Rae Street, Stockport, artist and designer; J. Ridgway, 55, Shaw Road, Stockport, advertising agent. Qualification £100. Remuneration as fixed by the company. Secretary: W. B. Price. Registered Office: Mansion House Chambers, High Street, Stockport.

News and Notes.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—At the annual general meeting held on January 19, Dr. B. T. J. Glover was elected president for the present year, Mr. J. Mansell treasurer, and Mr. Frederick S. Richards hon. secretary.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—Mr. E. C. Ridge has resigned the position as secretary which he has filled during the past eight years. He is succeeded by Mr. W. M. Bond, 24, Henningham Road, Lordship Lane, London, N.17. Meetings of the society will in future begin at 7.45 instead of 8.30.

MR. H. C. MESSER, who for many years has been in business as a photographer in Salisbury, has returned to his native Ealing, having acquired the studio of Mr. F. C. Vinall at 7, Florence Terrace, Ealing, London, W.5. Mr. Messer has disposed of his Salisbury business to Mr. A. E. Cox, his manager there for some months past.

LEYTONSTONE CAMERA CLUB.—This club is arranging an exhibition to be held from March 16 to 18 at St. Catherine's Hall, Leytonstone. There is one open class in which, as also in all the advanced classes arranged for members, a plaque will be awarded. The latest date for receipt of entry forms and exhibits is February 28. Prospectus and entry form from Mr. Sidney W. Liddell, Cliddesden, 29, Fillebrook Road, Leytonstone, E.11.

A MAGISTRATE-PHOTOGRAPHER.—There was an unusual incident at the Hay Police Court last week during the hearing of the Armstrong poisoning case. A daily paper states that on the bench was a magistrate who had not been taking part in the proceedings. When the acting magistrates retired to consult in private, he produced a small camera and took a photograph of Armstrong, who at the moment was leaning over the dock to consult his solicitor.

THE CARBRO PROCESS.—The Autotype Company sends a 16-page booklet on the Carbro process, written by Mr. A. C. Braham, and embodying the very practical instruction in the process which Mr. Braham gives in his society demonstrations. The booklet is obtainable free on application to 74, New Oxford Street, London, W.C.1. The demonstrations of the Carbro process at this address, which have been given during January, have been so well attended that the Autotype Company is continuing them during the present month.

"THE CLUB PHOTOGRAPHER" for February is a Manchester number, and includes contributions by a number of writers of note. Mr. S. Grimshaw has a good many hints to give from his long experience in the Bromoil process; Mr. James Shaw lets us into some of the secrets of his superlative technique in lantern slide making; and Mr. Raymond Crowther discourses on the way one should go in the fixing of plates and papers. There is another article on Bromoil by Mr. James R. watt, describing and illustrating the making of a press for the transfer process.

BAB'S TALBOTYPE BALLAD.—A long-lost "Bab Ballad," written and illustrated by the late Sir W. S. Gilbert, but never published in book form with his other famous Ballads, appeared in last Monday's "Daily Chronicle," though it appeared originally in "Fun" on July 4, 1868. The ballad tells of the doings of "Sir Conrad Talbotype, of Talbotypetonneville." The name of the knight must have been suggested to Gilbert by the Talbotype (or Calotype) process. There are, however, no other photographic words in the ballad.

"THE PROFESSIONAL PHOTOGRAPHER."—In the January issue Messrs. Kodak, Ltd., have an illustrated interview with two Midland photographers, Mr. H. H. and A. J. C. Dudley, of West Bromwich. There is an interesting account of the work of Mr. Dudley Hoyt, of New York, and among the advertisements we notice the first announcement of the Eastman portrait diffusion discs for attachment to any lens, converting the latter into an instrument giving one or other, according to the choice of the disc, of two moderate degrees of diffused definition.

PRIZES FOR MOTHER AND CHILD PORTRAITS.—A first prize of £100 is offered by the "Weekly Dispatch" for the most effective photograph showing a mother and child, the age-limit for the child being eight years. Photographs are invited from all over the British Isles, and second and third prizes of £25 and £10 are also offered. During the run of the competition interim prizes of £5 5s., £2 2s. and £1 1s. will be given for the best photographs reaching the "Weekly Dispatch" during any individual week. Simultaneously a similar "Grandmother and Child" competition will run its course with a £10 first prize.

THE LONDON CAMERA EXCHANGE CO., LTD.—Messrs. Robbins & Manstre, of 2, Poultry, Cheapside, London, E.C.2, is a firm of dealers in secondhand apparatus which has so soundly established its position for fair dealing in buying and selling that its periodical catalogues of the goods which it offers for sale are of more than ordinary interest. The present list consists of 64 pages of itemised descriptions of apparatus in the way of enlargers, vest-pocket and other small cameras, reflex cameras, folding focal-plane and other hand and stand cameras, lenses and miscellaneous instruments. The variety of goods described in these pages should afford the widest opportunity of choice on the part of purchasers of equipment for the coming season.

PROCESS WORK AND THE PRINTER.—The house organ of Messrs. Penrose & Co., 109, Farringdon Road, which for many years has been issued as "Process Work," will shortly make its appearance as an independent public journal of the title "Process Work and the Printer." It will appear quarterly, and will consist of at least twelve large quarto pages of text, together with specimens of the latest processes in photo-mechanical reproduction and printing. Publication has been transferred to Messrs. Percy Lund, Humphries & Co., Ltd., by whom the new journal will be printed. Under the editorship of Mr. William Gamble, head of Messrs. Penrose & Co., the endeavour will be to make the new journal of the greatest technical interest. The annual subscription will be 5s., post free 6s.

BURNS FROM THE RESULT OF FIRING FLASH POWDER

To the Editors.

GENTLEMEN,—Recently I was taking a flashlight photograph of a very big fancy dress ball, and on filling a German flash lamp with powder the lamp sprang slipped and fired 4 ozs. of the powder, including what was left in the tin. Being in the country and no doctor handy I was taken into a farm house with

terrible burns on my right hand and arm. The farmer's wife applied what I think was a very simple remedy She took about 2 *to* 4 *ozs. of carbonate of soda, grated a raw potato*, and mixed the two into a sloppy poultice (cold). She applied this on a piece of linen, and completely enclosed my hand and arm. The pain went in five minutes, and I had no further trouble. The plaster was kept on for two days, after which I smeared the parts with zinc ointment until all the skin had healed. In a week I was quite cured. My camera case now always contains a supply of carbonate of soda, some lint, and a good-sized potato in case of accidents.

B. Hollins.

16, Oxford Street, Harrogate

THE P.P.A. CONGRESS.

To the Editors.

Gentlemen,—Many thanks for inserting my letter last week. Mr. Lang Sims' statement in the same issue, explaining the reason which decided the Council to alter the time and venue of the 1922 Congress, put an altogether different complexion on the matter. I trust it will satisfy the majority of our members as it does myself, and I hope when the time comes to be able to attend the Congress, and that its success will reward the Council.—Faithfully yours,

S. H. Greenway.

27a, Abington Street,
Northampton,
January 25.

To the Editors.

Gentlemen,—My attention has been directed to a paragraph in last week's issue on the above subject by one who signs himself "Scottie," inviting me as President to give my opinion on the change of date of the Congress.

If the gentleman will kindly put his name and address to the letter I will gladly answer his question. I do not think he honours dear old Scotland by withholding these.

A. Swan Watson,
President P.P.A.

Viewpark Studios,
Edinburgh.

To the Editors.

Gentlemen,—The manifesto of the Council of the P.P.A., recently published in the "B.J.," conveys the impression that its authors are beginning to realise that their action in removing the Congress and altering its time of meeting, on their own responsibility, without having taken any steps to ascertain the wishes of the members generally, has led them into an awkward position. The Congresses hitherto have been most successful. The difficulties arising from the now alleged want of sufficient accommodation have not been apparent, and have not marred the enjoyment. The inherent features of such a gathering, under the circumstances, its picnicky character, the fullness of life and movement, the casualness and the absence of formality, all combined in promoting that freedom of intercourse so essential to success. Under the new conditions, under a different atmosphere, that of aristocracy and fashion, the proceedings, no doubt, will be conducted with a solemnity suitable to the locality. We may gain in dignity, which we do not want, but we shall certainly lose that holiday spirit that we do want.

In my business in a country town over 200 miles from London I am dependent for any knowledge of what novelties and kinds of materials, etc., there are in the market upon the visits of travellers, and for that reason I have been accustomed to pay an annual visit to London in the spring to look round. To join the Congresses, of which I have attended all except the first, has therefore exactly suited me; for in the Fair I have been able to find, gathered under one roof, all the principal dealers have to offer, leaving me plenty of time to join in the outings and festivities of the Congress. I cannot afford two journeys, so in future I lose the Congress. If the Council had shown that any material advantage would follow the change I should have accepted the position in silence; but I feel sure that if the members had been consulted a considerable proportion would have voted for the old lines being followed. There could have been no difficulty in obtaining the views of the members. What is the P.P.A. Circular for?

By the way, why was the Circular stopped? Every number was full of glowing testimonies to its usefulness, and, beyond frantic appeals to pay subscriptions, hardly anything else. Just when its real usefulness arises, it stops. That the Council was so overworked in the business of the incorporation is an excuse that does not appeal to one's reason. Then again, what was the actual motive for turning the Association into a limited liability company? When I first joined there was an accumulated fund of about £200. That amount has steadily increased to over £1,000, a sum quite sufficient to cover any loss or expense that could be reasonably incurred under careful management. Do the Council contemplate any enterprise of such highly speculative nature as to involve a risk of swallowing up their reserve, still leaving a liability for more? If not, why have they accepted the serious inconvenience of working under the restrictions and obligations of the Companies Acts in return for a protection that should never be required? Some of us used to think the Council's policy safe, but unenterprising; are we to read the signs of the times that in future it will be enterprising but unsafe?

A Country Member.

To the Editors.

Gentlemen,—The correspondence *re* P.P.A. has been very interesting, and having been a member since the start and attended every Congress, I should like to state my views. There is no doubt, in my mind, that the autumn Congress will be a failure without the Photographic Fair. The latter, in my opinion, is of equal importance to the Congress, and a decision of this sort should have been arrived at only by a referendum of members.

With regard to last Congress, it is evident that other members than myself were highly amused at the almost childish way the Council acted on every occasion—at the Guildhall, at Messrs. Kodak's, and on every public appearance. In fact, one almost felt afraid to touch the hem of their garments, particularly at the Guildhall, where special seats were reserved for "Council only." Then as to the Circular. This effusion cost a great deal of money and contained nothing but what had already appeared in your splendid journal, and certainly was of no value to any professional, but a repeated account of Council meetings.

Well, gentlemen, I trust no one will think I do not value the Association. I do and shall hope it will prosper, but let us have the Congress and Show together in April, when we can all spare the time, and let the Council drop the autocratic manners. They are only in that position by reason of the members' votes. Also let them give us lectures that are of educational value, not slides showing results only, but how to obtain those results, and so make the Association of real benefit to all its members.—Faithfully yours,

Fred Gegg.

THE INCOMPETENCE OF THE AVERAGE PHOTOGRAPHIC ASSISTANT.

To the Editors.

Gentlemen,—With reference to "Belgravia's" letter, in which he deplores the incompetence of the average photographic assistant, it seems that he must be either very unlucky in his search for a "really competent" finisher or very fastidious!

It is, of course, well known that there are a good number of "dud" workers, but this can be said of all trades and professions.

To a very great extent photographers themselves are to blame for this state of affairs. We call photography a "profession" Ye gods! Yet it is common knowledge that for unprofessional-like methods photographers are hard to beat. This is particularly obvious in the engaging of assistants. In an interview it is always "What salary do you require?" not "What can you do?" and the applicant who asks the lowest figure obtains the situation.

How many employers do we meet who take an interest in their assistants? How many who will listen to practical suggestions for the improvement of the work? Why is it that in one studio over-

time is paid and at another place it is *not*! This especially applies to Christmastime. Why do not employers spend a little more money on their workrooms instead of calling a cellar "my printing room, you know!" or an ill-ventilated shed "our dark room." Of course, it sounds very splendid to customers—who never see behind the scenes—but does it tend to make the assistants efficient or interested in their work. Even some of the high-class West-end studios do not provide workrooms or equipment which could be called even "fair." I also recall certain studios where the staff was mostly composed of "learners."

Certain successful photographers *do* adopt business methods, and it is reflected in the efficiency of their staff. But efficiency costs a little extra money. Therefore Mr. Average Photographer—penny wise and pound foolish—prefers to pay less and puts up with "dud" workers.

I agree with "Belgravia" that in the States assistants are thoroughly looked after and properly trained, but it is too much to expect in this tight little island, where the employer refuses to treat his assistants as human beings.

Here is a chance for the P.P.A. to shine—and earn the gratitude of efficient assistants—by standardising wages in photography, and generally helping the cause of the assistant.

I hope, gentlemen, you will excuse the length of this letter, but my excuse, if one is needed, is the fact that the assistant does not obtain a hearing in your columns too often.—Yours truly,

I Gotta Job.

To the Editors.

Gentlemen,—I agree with what "Belgravia" has said, as far as it goes, and I write with considerable knowledge of the subject. I have heard that the American photographers do surpass ours in "putting their apprentices and assistants through it," but even in the finest studios in the world, American or otherwise, they do not keep teachers on the premises, but only highly-skilled workers, who are not always ready and willing to impart their expert knowledge to apprentices, even if gifted with the ability to teach, for they feel that they have been engaged as workers only, and paid only for their services, and not as teachers. They also hear the little bird twittering in their ears that sometimes old employees are sacked to make way for younger and more energetic men or women, and so, if they do teach, or try to teach, more often than not it is in a very indifferent and careless manner—it is nothing to them, but they cannot refuse very well; but just think of the limited scope for teaching offered to even the cleverest workers in a studio, only an occasional apprentice. Teachers are not made by such slip-shop occasional methods as those.

Most apprentices learn, according to my experience, a fair amount about operating, a good deal about all kinds of printing, mounting, spotting, general usefulness in the studio in the "fetch and carry" direction, but when it comes to negative retouching, finishing enlargements in monchrome or colours, miniature painting and tinting, pastels, etc., well, out of every ten old apprentices or assistants who have come to me for lessons in the above-named branches I have found that quite seven have been very badly taught indeed, and I have invariably had to make them discard nearly all their acquired methods, and have had to make them commence from the very beginning.

I do not blame the photographers, for, as stated, they are not teachers, and teaching is an art in itself, and whilst one of the workers may be trying to teach an occasional apprentice, I have taken in hand hundreds during the 25 years that I have been teaching the beginner or improving and quickening the slow or defective retoucher or artist, and since I originated my postal system of lessons on the art side of photography I have, with the help of a little band of real West-end experts, given thousands of postal and personal lessons. I had considerable trouble in finding these artists willing to help me in my scheme of tuition, and it has taken me years to accomplish my purpose, but I have them now, men who are, and have been, chief finishers for many year to noted houses. I also arrange for lessons in posing and lighting by an F.R.P.S. who has been chief operator for leading West-end studios. Printing, developing and general routine of the studio and dark-room are also taught. A pupil takes up one or two subjects, and in six lessons in each will learn more than in a three years' apprenticeship, for the lessons are direct and concentrated, and the pupil gathers the fruits of the teachers' 30 years' experience as a high-grade practical worker, and is never turned away with "a little about everything," but knows a very great deal about the subjects studied.

Many of my pupils have become head workers for West-end studios, some have splendid studios of their own here and abroad, many have become trade workers, all have made good progress, and some have displayed genius. I have taught for the Ministry of Labour, and am on their list, after several interviews and very close scrutiny of my qualifications, and the pupils they have sent to me have made excellent progress. I have no classes, but every pupil has lessons directed solely to his or her advancement, and everything is done to really teach the subject taken up. Class-work means divided attention, and therefore cannot be as quick in its results or as effective as purely individual instruction. I and my little staff of expert instructors are prepared to take in hand all those who feel that they are slow or defective in their results and working, or who wish to begin from the first rung of the ladder.

I will guarantee to advance them quickly and effectively, and in the case of apprentices who are earning "15s. per week" after "three years in a high-class West-end studio," and who need "finishing off" (if not commencing from the beginning), I will give them this hope: "Men (and women) may rise on stepping stones of their dead selves to higher things," and, I can assure them, higher wages.—I am, yours faithfully,

T. S. Bruce.

January 30.

METOL POISONING.

To the Editors.

Gentlemen,—Having been a martyr to the above poisoning for many years, and having at last cured myself, no doubt many of your readers would like to know the remedy. I have tried every ointment and treatment, including the medical baths at Harrogate, without any result.

I take 4 ozs. of soda carbonate to 1 pint of boiling water (after the day's work), place my hands in the solution, and soak for 15 minutes, or until water becomes cool, and all the itching of the skin disappears. I then dry hands thoroughly, and then rub well in the "B.J." remedy for metol poisoning, viz.:—

Ichthyol	10 grs.
Lanoline	40 grs.
Boric acid	40 grs.
Vaseline	30 grs.

Well rubbed into affected parts three times daily.

When using M.Q. developer I keep a dish containing 20 drops hydrochloric acid to 1 pint of water, and immerse the hands before, during and after development. Since using the above I have not had the slightest trace.—Yours truly,

Bernard Hollins.

16, Oxford Street, Harrogate.
January 24.

THE FIRST TEXT BOOK OF BROMIDE PRINTING.

To the Editors.

Gentlemen,—I read with great pleasure Mr. Woods' communication in your last issue. It is interesting in more ways than one, for it recalls many memories of the old days, and the discussion on the advance of gelatine bromide emolsion.

I can safely confirm your note to Mr. Woods' letter, for when I came here I had the Polytechnic formula by Howard Farmer in my note-book, and found my father busy with Abney's "Photography with Emulsions" in 1883, and enlarging with Morgan and Kidd's paper by daylight. When the clouds were favourable he produced some good toned enlargements with the ferrous, or a late developer which Morgan and Kidd recommended.—Yours faithfully,

Henry Holman.

Banff, January 30.

SHARPENING RETOUCHING PENCILS.

To the Editors.

Gentlemen,—With reference to recent hints in your Journal, on quick ways of obtaining a good point on a retouching pencil, I find a carborundum wheel the quickest and best means, a few turns of the wheel, whilst holding a pencil to the side of the stone, and a perfect point is obtained; of course, the pencil must be slowly turned round, and the finest or smoothest stone used. In less than half a minute a new lead can be sharpened to a perfect point.—Yours faithfully,

SWEATMAN HEDGELAND.

Broadway, Maidstone, January 30, 1922.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

D. W.—Most London photographers get their blinds from the large furnishing houses, such as Maple, Shoolbred or Waring. You might ask for estimates from them, and also from John Hall and Sons, blind makers, 217, Hornsey Road, London, N.7. Ask for metal barrel roller blinds.

W. H.—The best advice we can give you is that you write to the Kodak Co. for their booklet, "Photographing Paintings," which was written by an expert copyist of paintings, who previously had contributed much of the matter in the shape of articles in the "B.J." You will find that panchromatic plates are almost essential, and require to be used with a relatively deep screen, such as K3.

R. B.—The book is "Minutes of Proceedings of Thirty-ninth Annual Convention, Photographers' Association of America." The secretary is Mr. J. C. Abel, 421, Caxton Building, Cleveland, Ohio, U.S.A., from whom no doubt a copy is obtainable. We do not know the price, and apparently the book is not on public sale, but very likely the Association would send you a copy by way of courtesy.

E. E. E.—We have indicated the smallest area of glass with which you will be able to work effectively. If you are likely to take large groups, we should recommend extending the light as far as the dotted lines. You would, of course, only be able to take groups or full-lengths at one end of the studio, but could manage heads or half-lengths by placing the background at B 2; with a fairly short-focus lens you could take full lengths this way of the studio. It would practically necessitate rebuilding the whole structure to convert it into a single slant studio.

N. Z.—We think it is going rather too far to adopt a card of the form which you attach to your letter, since this suggests, to our mind, that you are a representative of the papers. There would be no objection if you put above the names of the papers the words, "Contributor of photographs to." It seems to us that this is an ordinary measure of precaution, for the reason that no doubt the papers have representatives in your district, and unless you do something such as we suggest, you are likely to invite unfavourable notice from any authorities who know of the existence of the other Press photographers holding official commissions from the papers.

C. H.—Almost all the printing-boxes on the market can be obtained in models suitable for a gas illuminant. An inverted mantle burner is exceedingly suitable for a vertical enlarger, but with the exception of the expensive outfits, such as the Eastman Projection Printer, there are no vertical enlargers on the market. We have an article in type, to appear within the next week or so, describing exactly how to make a vertical enlarger for gas illumination. As regards a ceiling light, it is not so easy to adapt gas, but quite practicable to suspend a large box from the ceiling with a canary fabric covering on its upper open end, and an inverted mantle fitted in it. In this case you must have the inside of the box of ample size, and painted a matt white. We should think perhaps it would be better to discard the idea of a ceiling light in favour of a lamp hung a foot or so from the wall and fitted with an upright burner, a direct light from which through the canary fabric would be cast on the wall and reflected as a dim illumination throughout the room. The worst of gas for these ceiling lamps is that you must provide ample openings for entrance of air and escape of the products of combustion, and, at the same time, must light-trap these.

J. B.—We are sorry that we do not know formulæ for emulsion for direct positive cards or plates. So far as we know, no such formulæ have been published. We should have thought that you could get on quite satisfactorily with the sensitive materials supplied by either the Quta Co., 252-254, Haydon's Road, Wimbledon, London, S.W.19; Magna Co., 2, Eastborough, Scarborough; or Moore and Co., 101-103, Dale Street, Liverpool. A formula for a combined developer-fixer for ferrotype plates is as follows:—

Water to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

C. R.—We advise you first of all to copy the print on to a process plate, preferably through a blue filter, as by putting the print behind a thin blue glass. Methods of restoring are very uncertain, but we give details of processes which have been recommended:—One process is to bleach the yellowed print in a mercuric chloride solution, as used for intensifying, well wash, and then to develop in an old hydroquinone or metol developer (without bromide), or preferably to immerse in a 5 per cent. solution of sodium sulphite, and, finally, wash well. This process is not reliable. An elaborate process of restoring silver prints, and one for which the inventor (H. Jandaurek) was awarded a silver medal in 1888, is as follows. Two solutions are required:—

A.	Distilled water	45 ozs.	1,000 c.c.s.
	Sodium tungstate	608 grs.	5 gms.
B.	Distilled water	1 oz.	400 c.c.s
	Calcium carbonate (pure)	5 grs.	4 gms.
	Chloride of lime	1.2 grs.	1 gms.
	Gold and sodium chloride	5 grs.	4 gms.

The B solution should be kept in a yellow bottle, or in the dark for twenty-four hours. The faded prints are unmounted, well washed, and placed in 8 ozs. of the A solution, to which ¼ oz. to ½ oz. of B has been added. They should remain in this toning bath until they assume a good purple tone, and they are then well washed a fixed with "hypo" (1 oz. to 10 ozs. of water) until all the yellowness has disappeared, which may take one hour or more; finally they are washed well.

IMPORTANT NOTICE TO READERS.—Until further notice agents will supply the "B. J." to order only, as the high price prevailing for everything in connection with newspaper production prohibits the distribution of surplus copies for chance sales. It is therefore necessary in order to ensure the regular delivery of the "B. J." to place an order definitely with a dealer, newsagent or bookstall clerk, or to send a subscription to the publishers.

HENRY GREENWOOD & Co., LTD., Proprietors and Publishers, 24, Wellington Street, London, W.C.2.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3223. Vol. LXIX. FRIDAY, FEBRUARY 10, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. Charles H. Davis, the accomplished New York photographer, who has just held a one-man exhibition of his works in that city, contributes an article full of suggestions for composition in the posing of sitters for portraits. (P. 75.)

The making of portraits, specially with a view to colouring, is the subject of an article by an expert colourist. (P. 77.)

In the present period of depression we offer for consideration by portrait photographers a national advertising campaign which, if carried out efficiently, should very greatly increase the demand for photographic portraiture. The suggestion is based on the broad view that in the bulk photographers' competitors are the firms offering goods which are not necessaries of life. (P. 74.)

Unfavourable comment has been made on the announcement that only two cameras are to be allowed in Westminster Abbey on the occasion of the marriage ceremony of Princess Mary. (P. 78.)

In a contributed article Thermit describes how prints which refused to tone in the hypo-alum bath were made to do so rapidly by immersion first in a solution of hypo and then in one of 1 14 sulphuric acid. (P. 80.)

The Eastman Research Laboratory has reported on the use of successive baths of sulphuric acid and hypo as an odourless method of sepia toning. Similar processes were recommended some nine or ten years ago. (P. 74.)

Mr. J. G. F. Druce, reviewing recent work in France on the preservation of the amidol developed, states that amidol may be manufactured so that minute traces of tin salts remaining in it act as a preservative of the developer when subsequently dissolved with the customary proportion of sulphite. (P. 81.)

Unequal reduction of individual prints of a batch of bromides by longer or shorter immersion in an acid fixing bath may be avoided by following one or other of two plans. (P. 74.)

Developers for the production of relief prints by tanning of the gelatine in proportion to the amount of silver produced in different parts of the image are the subject of a recent patent specification. (P. 82.)

The humour of optics appears to dog the steps of Mr. C. P. Crowther; at the Croydon Camera Club the lurking power of a fierce focus aroused comment. (P. 85.)

At the Royal Photographic Society, on Tuesday evening last, Mr. Oswald J. Wilkinson described his practice of using flashlight for obtaining records of Nature subjects by night. (P. 84.)

A camera for making records of race finishes has been patented by a German optical firm. (P. 82.)

A gas water heater for a photographic workroom may be of one or other of two convenient patterns. (P. 73.)

Ample exposure of the warm-tone development papers is recommended in order to secure the full warmth of tone of which they are capable. (P. 74.)

EX CATHEDRA.

Workroom Water Heaters. The convenience of a constant supply of hot water in photographic workrooms is perhaps not appreciated as much as it should be by many photographic employers, not only on account of the saving of time and labour in making up solutions, but also as regards the comfort of assistants. Where hot water is not provided throughout an establishment from a central boiler it is a comparatively simple matter to fit, in rooms which require it, a gas water-heater which is quite efficient for the ordinary moderate requirements. These heaters are of two types, namely, those which give a moderate flow of hot water within a few seconds of lighting a gas-burner of fairly large size, and those in which a few gallons of water are kept hot in a tank by a burner which is automatically lowered as soon as the water reaches a certain temperature, the flame likewise automatically increasing when cold water enters to take the place of the hot which is drawn off. Both these types are supplied in several sizes by makers of gas-heating appliances, such as Messrs. Fletcher Russell of Warrington, Messrs. Parkinson of Birmingham, and other firms. The tank type is certainly the more convenient of the two and is obtainable in several very neat models, ranging in size from one which can be conveniently fitted over a lavatory basin to others designed for keeping at hand a dozen gallons or more of hot water.

* * *

Accelerating Hypo-Alum. By a coincidence there came into our hands almost simultaneously a few days ago the manuscript of the article by our contributor "Thermit," which appears on another page, and the December (1921) issue of the Kodak Abstract Bulletin containing a note on odourless sulphide toning. It will be noticed that "Thermit" ascribes a great advantage as regards acceleration of toning to the successive immersion of prints in hypo solution and then in one of sulphuric acid before transference to the ordinary hypo-alum bath. The report from the Eastman Laboratory describes a process which has been found practicable for sulphide toning, consisting in immersing prints first in 5 per cent. sulphuric acid for about 10 minutes, and then, after a brief rinse in 20 per cent. hypo solution saturated with borax, again for 10 minutes. Apparently, no heat is used, according to the Eastman process, the toning taking place, so we infer, chiefly in the subsequent half-hour's washing. Both writers ascribe the activity of the method to the formation of finely divided sulphur in contact with the silver image in the gelatine coating on the prints. Curiously enough, however, both writers appear to be unaware that a very similar method was advocated independently some years ago by MM. Lumière and Seyewetz ("B.J. Almanac," 1914, p. 660), and by Mr. H. Soar on page 662 of the same volume. MM. Lumière and Seyewetz used a mixture of hypo and dextrine to which hydrochloric acid was added imme-

diately before use. Mr. Soar immersed prints for about 20 minutes in a mixture of hypo and sulphuric acid. Both these earlier workers emphasised the fact that the sepia tone is obtained during the subsequent washing process. For commercial purposes this method has its drawbacks, and "Thermit's" present suggestion of employing the method as an accelerator of the ordinary hot hypo-alum toning bath appears to have advantages which are not possessed by the other variations of the process.

* * *

Pretty Negatives. It is rather a pity that it is impossible to establish any definite standard of quality for photographic negatives. We have, of course, the chemist's ideal of pure metallic silver embedded in pure gelatine, but unfortunately there are many negatives that do not answer to this description which yield most perfect prints. While pyro with ammonia or soda was universally used, the majority of negatives were not altogether pleasing to the eye, but they were usually of excellent printing quality. With the advent of the many non-staining reducing agents the visual quality of the negative improved, but often there was a distinct deterioration in the finished work. The principal difference is in the printing value of the shadow detail, which in an amidol- or metol-developed negative entirely depends upon the reduced silver, but which in the pyro-developed image is reinforced by the well-known yellow stain. Even if the clear portions of a pyro negative are colourless, there is a slight yellow stain under the image, and this has considerable light-resisting power. The obvious course for users of non-staining developers is to expose rather more, so that the weakness of the deposit in the shadows is overcome.

* * *

Unwanted Reduction. It is not recognised by all bromide printers that under certain conditions the acid fixing bath acts as a fairly powerful reducer, so much so that if a large number of prints from the same negative is made, and the first allowed to remain in the bath until the last is fixed, there will be much inequality in depth, although the exposure and development of all have been uniform. It seems that a large proportion of acid and the presence of developer carried in by the prints are the principal factors in producing this effect, so that the evil may be minimised by careful mixing of the solution and thorough rinsing of the prints. At the cost of a little extra work the prints may be preserved from over-fixing by following the old plan of numbering them on the back before exposure, and developing in the same order, it being then quite simple to remove the earlier ones from the fixer before they are spoiled. Another plan that has been worked successfully is to have two fixing baths, so that a certain number can be placed in each alternately, that is to say, two dozen prints, or fewer, are put into bath No. 1, and a like number into No. 2. As soon as No. 2 is filled the prints are taken out of No. 1, which, when filled, again gives the signal to empty No. 2, and so on.

* * *

Slow Papers and Warm Tones. There are now several developing papers with which warm black, if not actual dark brown, tones can be obtained by development alone without toning, but it is necessary that the special instructions given for exposure and toning be exactly followed. It is too much to expect that a special paper will give the best tones with any developer which the photographer happens to be using. The makers of one brand of paper direct that the exposure be adjusted so that development is complete in two minutes. This we have found cannot be disregarded with impunity. As there is, unfortunately, no standard of speed in bromide papers, many printers do not realise the great length of exposure necessary to get rich prints with warm tones. A recent experiment showed that a hundred times the exposure which was sufficient for a well-known bromide paper was just right for the warm-toned one. It is obviously necessary to provide a much more powerful light for exposing if much work has to be done, especially if vigorous negatives which yield the best results are being printed from. The smaller half-watt lamps come in handily for this.

MORE BUSINESS IN PORTRAITS.

In common with many other businesses not concerned with the necessities of life the circumstances of the time, as is hardly necessary to point out, have pressed and continue to press severely upon photographic studios. There is no doubt that the pressure is most heavily felt by firms in the industrial districts where unemployment among the working classes is more acute. Among studios whose customers are found among the well-to-do, many of whom remain prosperous under the present bad industrial conditions, the present depression is by no means so pronounced. Nevertheless, those who cater for the most fashionable and wealthy are doubtless making comparisons between their present turnover and that of the boom period preceding and succeeding the date of the Armistice. As regards these experiences it is worth while to recall the maxim that the time when conditions are bad is pre-eminently the time for consideration of new methods by which things can be permanently improved. While some of the symptoms of the present depression cannot possibly be remedied, except by removal of the causes, in particular the crucial handicaps of unemployment and excessive taxation, one cannot see any evidence of effort on the part of photographers to stimulate business during the depressed period. The usual argument is: "Times are bad; there is a slump; photography is a luxury, and must necessarily be one of the first businesses to suffer. It is inevitable, and we must put up with it."

The people who supply gramophones, pianos, and other musical instruments; furs, feathers, hats and fancy clothing of all kinds; pictures, books, motor-cars, bicycles, and numerous other articles, are all engaged in providing luxuries. All these people have suffered during the quiet time. They would, however, have suffered a great deal more—and many of them would have gone into bankruptcy—if they had shown no more enterprise and no more energy and foresight than many professional photographers have shown.

It is a good plan to watch what your competitors are doing. Every professional photographer ought to ask himself the question: "Who are my competitors?" Too often he looks upon the other two or three photographers in the town as his only rivals, whereas his real competitors are the people engaged in the trades just mentioned—the trades that are kept going entirely by the spare cash of the public. When you compare the efforts of these people with the efforts of the professional photographer, it is easy to see why photography has suffered to a much greater extent than other luxury trades. What is the remedy? What can photographers do to increase business? The answer is: Let them watch their competitors

The average citizen cannot take up his daily paper or his monthly magazine; cannot, indeed, walk along the street without having a hundred suggestions put to him for getting rid of his spare cash. He is told that he ought to make his home more cheerful by treating himself and his family to a piano, or some other musical instrument. A hint is thrown out to him that he is missing

one of the greatest pleasures of life by not being able to spend his week-ends driving round the country in a motor-car. He is also reminded that, to ensure the harmony of his household, he ought occasionally to treat his wife to a new hat. Rarely, however, is there anything to remind him that either he, his wife, or his children should have their photographs taken.

Now and again a photographer has put an advertisement in a local paper or sent out a few circulars to selected residents in his district, but notwithstanding this, it may be said with absolute truthfulness that professional photographers as a whole have done nothing whatever to popularise photography or to stimulate the demand for portraits. As a matter of fact, the person who has his portrait taken to-day must be in dead earnest; it must be an experienced need on his part, because certainly professional photographers in concert have done nothing to persuade him.

What is wanted is this—advertising to increase the volume of business—not one man advertising his own particular studio and saying nothing more effective than that he makes better portraits than somebody else. The interest in portraiture should be stimulated, and then every photographer would benefit. The value of co-operative advertising is now being realised by practically every trade. It is a remarkable testimony to the value of such a scheme that in America the Eastman Kodak Company spend a huge sum every year on advertising portraiture in the national Press, while their only means of getting a return for this expenditure is in the increased amount of material sold to professional photographers.

Here, the gas companies have combined to advertise gas; the Scottish wool firms have combined to advertise Scottish wool; the Irish linen manufacturers have combined to advertise Irish linen, and the makers of various other products are following suit. Co-operative advertising has been tried and the result has been a tremendous success. The same method could be applied to professional photography with hopes of even greater success, because the ground is new and has never been touched by national advertising. It would be a fairly safe prophecy to say that, if every professional in the British Isles would subscribe £5 a year to a fund for advertising photography to the public, the volume of photographic business could be doubled in the first twelve months.

SUGGESTIONS FOR PORTRAIT PHOTOGRAPHY.

In posing the sitter for a portrait it is well to always remember that people seldom sit bolt upright, "at attention," except when conscious of being under observation; that is, to put it another way, they always incline the body more or less and tilt the head at various angles, and frequently (not always) assume postures of ease and grace. If you cultivate the habit of acute observation you will come to see all these things unconsciously, and you will discover that it is easy to *find poses* that command admiration and insure the satisfaction of your clientele.

Watch people in public places, in carriages, tramcars, omnibuses, and particularly groups of people on the street or elsewhere engaged in conversation. They are at ease. They are not conscious of being observed. There are no squared shoulders, protruding chins and a military stiffness of neck and head—but, speak to a person, and notice the self-conscious rigidity and lack of reposeful grace that instantly follows.

Hence I suggest in posing people for portraiture, avoid the rigidity and stiffness, or the outward appearance of it. Let your sitter be at ease, and if you are keenly observant you will find very little to change. Perhaps a wrinkle in a garment, a hand to be moved or turned to improve a line, or a slight turn of the head may be necessary.

I constantly remind my sitters that the head is almost universally and unconsciously carried on one side. I am obliged to do this because many, especially ladies, fear that an inclination of the head will produce an affected look in their portraits. The reverse is true. That "picture look" goes with rigidity; and conversely the slight inclinations of the head and body impart naturalness and grace. Likewise, when people are interested they tip the head. It makes for repose and ease, invariably, and furthermore, strange as it may seem, it indicates alertness and interest on the part of the subject when animated by the proper expression. So I repeat, always incline the head a trifle in finding the pose. Observe in passing that I say "find the pose." This is important. Seldom should it be necessary to "make" the pose. On the contrary it should nearly always be "found" by letting sitters move themselves. Never, hardly ever, touch the sitter's head. They resist, and stiffness results. Stand by your camera, where you can see the effect, and suggest, indicating sometimes by your own movements, and the sitter will readily fall into a satisfactory pose. This inclination of the head is just as requisite in a three-quarter face or a profile view as when the head is turned full upon the camera. A valuable lesson in head posing is to be found in the work of the ancient Greek sculptors. There exists a mask—sometimes called the "Mask of Diana"—that is a safe guide for nearly all head posing. This mask can be purchased at a moderate price in most plaster cast shops. When viewed from the front of the face, the oval outlines of the head of the mask flow uninterruptedly into those of the neck and shoulders, producing that absolute essential, the *swirl* or line of beauty. I have always maintained that no grace can exist in a head pose or in a figure, or groups of figures, unless the fundamental line (which often is invisible), is the S curve or the "line of beauty," as it is almost universally known. The masterpieces of figure composition proclaim this fact; and this is quite as true in sculpture as in painting—or in good draughtsmanship everywhere. You will observe it in the well-known figure called the Venus de Milo; also in the headless and majestic Victory which graces and dominates the grand staircase of the sculpture gallery of the Louvre in

The Mask of Diana

Paris. I mention these two famous art works because they are so well known, and because reduced copies in plaster are so cheap and available as studies. I recommend to all portrait photographers that they buy casts of these three works mentioned above—the Mask of Diana and the two figures—and keep them at hand for daily observation. It is a wise thing to have good casts always under one's immediate observation. To live with them assists in the study of lines; and the more familiar one becomes with the lines of grace as exemplified by these famous works, the easier it will be to discover the needed lines of beauty in the sitter for a photographic portrait. The line of beauty adds a note of charm wherever it is introduced. It should be the basic line of the figure, the returns being shown in the head at one end and the feet at the other. Let the arms repeat the line, or let some drapery or fold continue the arm line, completing it in a curve of beauty. The more this is observed the more one is surprised at its prevalence and repetition in all beautiful figure arrangements; and yet it is still more surprising to realise the ignorance of the average photographer regarding this underlying note of grace and beauty. It is a revelation to many when the line is pointed out. It is so easy to see after a little study, and so easy to introduce into a photographic portrait. Often a piece of drapery can be made to contribute the effect, even when stiff and formal garments do not readily lend themselves to its achievement.

However, the figure can nearly always be so disposed as to produce the desired effect; and having accomplished that much, little touches of the return curve are easily added and introduced. Teachers of art, I find, do not always realise the needed stress upon this feeling of grace. I remember once, when lecturing in Boston upon the attainment of grace in posing the figure, a young man, a photographer who was operating in a large studio, came to me afterwards at my hotel, and thanked me for the valuable instruction he had received. He said that he had studied at the New York Art League, and had been a constant visitor at the Metropolitan Museum of Art, and up to the time of my exposition of the line of beauty, he had never really understood what made a figure picture graceful. He could recognise the grace, and see the beauty, but he was unable to resolve the composition into its fundamental lines of beauty, so as to reintroduce them in a dissimilar composition. "But," he added, "you have made it clear to me now. I can see the lines, and I realise what to do to get them into the picture."

I therefore re-affirm that all great pictures, sculptures, and figure arrangements that are pleasing and delight the eye, are built upon the line of beauty. One does not need to go far to substantiate this statement. Look at the great picture by Guido Reni, "Aurora," so widely known for centuries. Almost universally the lines of its compositon are swirls—the S curve. Observe, if you will, Raphael's Madonna of the Chair. The magic of the composition is the marvellous way the painter has arranged his swirling lines—all of the kind that I am insisting upon. The face might be still more beautiful, but without the grace of line the picture would be deficient in charm. Take Bouguereau's famous works—which exhibit some of the most beautiful female figures ever put upon canvas—and you will find this delightful curve prevailing, even predominating. I could adduce thousands of instances in pictures that are world known. Boucher, the French master, was a disciple of the return curve, and few more elegant examples of perfect drawing, combined with exquisite colour and delicacy, exist. Fragonard even caused his trees to continue the lines of his figure arrangements, and they invariably terminated in the swirl. The works of these two famous French painters will richly repay study.

I again suggest to those who would increase their ability to make simple, natural, graceful poses for their patrons, to surround themselves with examples of good figure arrangements. There are other considerations besides self-instruction to be weighed in purchasing casts and good examples of the painter's art, and displayng them in one's studio. Your patrons judge your taste largely by what you permit them to see in evidence. If your reception room, dressing-rooms and light room are adorned only with a collection of portrait photographs, mostly of one small or moderate size, they are not likely to place your artistic standard very high. If, on the other hand, you display on your walls masterpieces of art—not merely photographs, unless they are high-grade carbon prints—their estimation of your taste will certainly be a higher one. Let me cite an instance. Among my artist friends in New York City is a young woman who is rapidly becoming a distinguished sculptor of world-wide renown. Only last year she was honoured by a purchase by the French Government of a bronze group, nearly life-size, which was erected under her supervision in the Jardin de Luxembourg in Paris. This is a most distinguished honour. The entrance passage-way to her studio is adorned with bas-reliefs by Michaelangelo, Della Robbia, and other renowned masters; and there are also many photographs of great works displayed for the visitor's inspection as he proceeds towards her lofty and beautiful studio. The impression is a subtle and masterly one. You feel that you are being ushered into the presence of an artist of rare taste, discrimination and great attainments. Everyone knows that a first impression is the one that invariably endures. Why not set the stage in our own studios as carefully and with as certain effect? It can be done. The results of such a display will impress your clients, and will also react upon you, the photographer, for it will inspire you and increase your appreciative powers, thus benefiting your work in portraiture. Patrons will have more confidence in your ability as an artist, which is certainly a consummation devoutly to be wished. The psychology of this idea is well known and appreciated by many successful workers in all branches of art. The greatest designer of architectural ornament I know in America is surrounded by, in his home and studio, replicas and photographs of the world's most beautiful works of art. These are his constant source of inspiration. His mind is saturated with the achievements of those who have trod his chosen pathway before him. The great artist, Alma Tadema, who devoted himself to figure paintings representing the beautiful mythology of Greece, lived in a home in St. John's Wood, London, that was a veritable Grecian temple. Its architecture and adornments appear in many of his canvases. This should be an object lesson for all of us who are devoting our lives to portraying the human figure.

Much of the facility in hand posing which the writer possesses has been acquired by the study of good sculpture. Many a lesson have I received from the works of Michaelangelo. Though he has been dead hundreds of years, his masterpieces remain and teach us, if we will but observe. Copies of good works of art are so accessible, even in the smallest towns, that there is no excuse for ignorance upon these subjects. The public libraries are full of books that demonstrate these theories of mine, which are the fundamentals of art; the "Perry pictures," little prints in half-tone selling at a half-penny each, are available; and the little pocket-size booklets published in London, each devoted to a master painter and his works, are to be had at prices within the reach of the leanest purse. Let me urge those who desire to progress to think of these things that are worth while; and it must be apparent to the dullest mind that the reward of study is to be found in the appreciation of one's patrons, and with it an increasing income.

You will find that artists like Rembrandt could not paint without introducing the line of beauty. His Holy Family and his many portraits of himself are pregnant with the lines. Do not imagine that this curve is only for women and children. It serves as faithfully in men's portraits, and unfailingly, too. There is no royal road to learning. This age-old adage applies most forcibly to art in photography, and there is no return more certain than the benefits to be derived from learn

ing to see, which is only another way of learning to draw; and one can draw with the camera as surely and as definitely as the painter with his brush. No one can produce beautiful things who cannot first envisage them. Innes, the famous landscapist, said: "You can do nothing in Art unless you have intuitions; but between whiles you must work hard in collecting the materials out of which 'intuitions' are made."

CHARLES H. DAVIS.

PORTRAITS FOR COLOURING.

THE "Ex Cathedra" paragraph, "Portraits for Colouring,"* was, doubtless, prompted by the realisation that too much colour work is being attempted on prints which are unsuitable. Although a good deal has been written concerning water-colour finishing it is apparent that various authors have given very slight advice on the production of a suitable print.

It is true to remark that print-requirements of individual colourists vary according to circumstances, and the chief of these circumstances are: The personal ability of the artist, the "style" in which the picture is to be finished; the price the work is to command, and the time allotted to it. Therefore, taking these factors into consideration, it will be realised that the *ideal* print, to suit all conditions, cannot be defined in an arbitrary manner; however, it is possible to give helpful, practical suggestions, and it is hoped thereby to fill a breach which hitherto has existed.

The Charm of Water-Colour.

If we examine the technique of water-colour painting it must be realised that the charm of this medium of expression is chiefly distinguished by its purity, transparency, and delicacy of colour; these characteristics, however, are not imparted without knowledge and experience. The artist is extremely particular in his choice of a suitable water-colour paper; in its care and use; the thorough cleanliness of his brushes, palette, and colours, together with their correct mixing and application.

To a great extent depth, or richness of effect, is attained by colour opposition, or "colour-contrast," and is not necessarily due to contrasts of light and shade; moreover, the beautiful white paper base, almost universally used, ensures pure colour with practically no appreciable alteration after application, for it is the more or less transparent properties of water-colour tints, in conjunction with a suitable base, that render such colours in all their purity and luminosity.

Comparisons.

The technique which we have considered applies to the colouring of a portrait photograph; the photographic print, however, introduces a new element, and that element has to be examined in combination with colour practice. In photography, pure and simple, we generally find a certain amount of contrast of light and shade essential in order to attain a measure of relief and solidity. Since, in colour work, this contrast is largely obtainable by means of colour opposition, monochrome contrast is not essentially so marked in a portrait which is to be coloured—in fact a rather light print, of a suitable tone, correct in tone-values and possessing but delicate contrasts, materially assists in attainment of colour purity, transparency and truthful harmony throughout the subject.

An Unsound Practice.

Regarding colour finishing as a higher branch it must become evident that the procedure ordinarily adopted in making a negative—on a colour-blind plate—does not always comply with the requirements which the foregoing implies; and, as it often happens that a coloured portrait is ordered from a negative already *so* made, it is no exaggeration to assert that this is the most prolific source of indifferent colour work.

In such cases it is true to say that "faking" may be resorted to; and if the end justifies the means there cannot be much objection. But it is neither so desirable—nor so sound in procedure—as the more direct method of arranging special sittings for work which is to be coloured. Therefore, in going to the root of the subject, it is considered that the matter will be of greater utility.

Personal.

Whether applied colour should be subordinated to the photographic basis, or *vice versa*, is perhaps a moot point. Personally, and regardless of purist opinion, I believe in the elimination of the photographic to the utmost practical extent in order that the finished work may, as nearly as possible, have the charm of the true water-colour; it is with this end in view that I much prefer to arrange a sitting for coloured orders.

Special Sittings.

Those who can turn out good coloured work, work rather above the average, will soon find that it is not so difficult to book a direct sitting for a colour portrait. Moreover, such sittings, being designed for the special purpose, are of benefit to sitter and photographer alike. Therefore, if any reputation is thought desirable one must specialise in this as in any other branch and the work must be planned in accordance with its special needs.

It has been stated that a *sine qua non* of good work is correct tonal, or colour rendering *in the negative*. In a good studio it often happens that a fair proportion of sitters are portrayed in fancy dress. These dresses can be, and usually are, composed of more or less gay colours, and, in addition, the subject's personal colouring is a variable factor. In these circumstances the ordinary plate and correct tone values do not often go hand-in-hand.

If the full advantages of a specially arranged sitting are to be ensured, the operator must be prepared to employ panchromatic plates, preferably with a suitable light-filter, in every case where the ordinary plate is likely to prove unequal to the task of correct colour translation. The employment of panchromatics is the one sound, direct method; the alternative is faking, which is undoubtedly, the less satisfactory and more troublesome procedure. Therefore, the adoption of the panchromatic is a long step towards trouble free, able workmanship.

In the Studio: Backgrounds.

Having arrived at this point we may consider the further formulation of practice suited to the desired end. In dealing with the subject of background, I will use a story which has a moral. I cannot recall the actual words, but I give them in effect. A father took his son to one of the old masters with a view to being apprenticed to learn portrait painting. In the interview the parent suggested the boy might be useful to the artist in painting in the backgrounds to his pictures. "In that case," said the master, "I have nothing to teach him."

The moral is obvious: the background, it is true, should be subservient, or secondary, to the subject proper; but this acknowledgment does not preclude the colouring, or composition, of the portrait being materially benefited by well considered judgment and the able execution of its background.

I have already remarked on the desirability of cutting out

* "B.J.," "Ex Cathedra," December 30, 1921.

the photographic to a great extent; if it is remembered that the painted scenic ground is not held in particularly high esteem in ordinary photography it should be apparent that its inclusion in a coloured portrait may constitute a mark of mediocrity. Therefore, in photographing a sitter for colour finishing, it is my invariable custom to use a white background—such as is commonly used for sketch portraiture; the ultimate clean, white base is a valuable acquirement to the colourist who has *carte blanche* in the matter of background finishing. Such a basis permits every possibility; it allows the skilled artist unrestricted scope without excluding the less skilled from finishing in a style less ambitious or masterly; the work may be carried to the margins in the solid style or it may be done as a vignette.

On the whole, the plain white ground answers so eminently well that any other is scarce worth consideration; any such consideration would assist in reducing the force of the plea for special sittings.

Lighting.

Contrast of light and shade is fatal; the lighting should be arranged in a higher key free from any suspicion of heavy shades; much the same kind of effect as has been recommended for sketch portraiture, *delicate, luminous shadows,* coupled with a full exposure and soft developing, materially assisting in the expression of those qualities so essential in good water-colour work.

The Basis.

Sufficient has been remarked to assist in the making of a negative, or the selection of an existing negative, which experience has taught to be most suitable from which to make a photographic basis for water-colour finishing; the basis or print, therefore, may now have attention.

Apart from small work and the superior permanency of carbon and platinotype, I do not consider the process of printing of great importance, particularly in view of the increasing use of the air-brush—for large areas of colour, at least. In point of fact, the process is often decided for the colourist, and for work of any size it very frequently happens to be bromide. If the print in this process is thoroughly fixed in double fixing baths, sulphide-toned, and very carefully washed after every chemical application, there ought not to be any fear for its reasonable permanence, and anything injurious to colours should be non-existent.

The nature of the surface and tint of the paper are important, and require careful consideration. A white base permits the utmost transparency and purity of colour. Moreover, the colourist can attain, thereon, any effect of which cream, buff, or other of the tinted papers are capable, without the corresponding alteration of colours their use would entail. A cream base might make no appreciable difference, but deeper tints would certainly modify applied colour.

The degree of smoothness or grain of a paper is largely a personal matter, and usually varies suitably with the size of the work; although it is good advice to say that no paper should be used which bears a suggestion of emulsion sheen—in other words, a perfectly dead matt surface is much the best.

Further Considerations.

Assuming that the process of printing has been decided there remain a few considerations. The ability of the colourist, and the price which is being obtained, have a bearing on the production of a print suitable to particular cases.

The skilled artist, as a rule, much prefers a very light print of sepia tone. Such a print appears yellowish, lacks modelling in the most delicate passages, and is weak in its darker portions. While the pale basis gives the drawing of the subject the clean lights and delicate, luminous deeper tones facilitate that invaluable clarity and transparency of colour which is so desirable. Likeness, richness and effect depend very much on the colourist's able modelling and distribution of colour; nevertheless, in capable hands, this type of print results in the best colour work.

Obviously, with the one exception of painting without a basis, this may be regarded as the highest branch of finishing; one must have ability and a price in proportion to the work. If the ability, or the price, or both are not forthcoming the case has to be met by a modified print. This is brought about by rather heavier printing—a print in itself more complete as a likeness and a picture.

Therefore, the deeper the print is made the less strained is the skill of the colourist, but as this depth of basis increases so does the purity and vitality of applied colour decrease until a point is reached where the work becomes unskilled and mediocre, and the impression is formed that the "coloured" portrait would have been much superior had it been nicely finished as a monochrome.

If skill or price be not of the best it is advisable to adopt a middle course and so arrange the print as to record the modelling, which is vital to true likeness, together with a little more general depth throughout. This will give "body" without so much dependence on after work; in these circumstances the value of panchromatic colour translation becomes more apparent.

Conclusion.

The endeavour to secure a suitable, nicely-conditioned foundation for colouring, on the lines indicated, is sure to show well-considered deliberation; and if original and skilful finish is the praiseworthy aim, this end will be greatly assisted if the usual stock photographic mount is eschewed. Indeed, the portrait will be greatly enhanced if it be mounted and framed in one or other of the styles more suitably adapted to ordinary water-colour practice.

PRUDENCE.

PHOTOGRAPHIC ARRANGEMENTS FOR THE ROYAL WEDDING.—According to the present arrangements, only two cameras are to be allowed in Westminster Abbey on the occasion of the Royal wedding on February 28, and a chorus of protests is being raised against the regulation. The "Star" had a lengthy and well-written article on the subject:—Authorities in the photographic world with a wide experience of the difficulties of taking interior pictures of a massed ceremonial fully endorse these views. Such an authority as Mr. Banfield, of Messrs. Foulsham and Banfield, when asked to express his opinion, characterised the arrangements as the height of absurdity. In view of the importance of the occasion he considers that not fewer than 18 to 20 photographers will be required.

"I would station them in different parts of the building," he said. "Some should be placed aloft to secure a bird's-eye view of the ceremony; some should be close at hand to record minute details of dress and expression. Some ought to be working at either side, and others again from the back.

"And I think it equally important that one or two should be placed with their backs to the altar so that they can include the crowd of distinguished guests."

Mr. Walter Stoneman, of Messrs. Russell, Baker Street, also condemns the arrangements. "Provided that Press photographers will remain in their places," he declared, "I think it extremely desirable that at the very least four photographers should be admitted.

"Apart from the chances of one of the cameras failing, light is an important factor in interior work. One photographer may be suitably placed under a window where the light falls directly on his subject, but the second photographer may find himself in a dimly-lit corner, and fail to secure a single good picture."

Apparently the authorities are afraid that the impressiveness of the ceremony may be disturbed by a continual clicking of cameras. But that apprehension is groundless. The first-class instruments used by the Press to-day work so silently that a person standing within a few feet may not be aware that a photograph is being taken.

THE PRACTICAL STEREO PHOTOGRAPHY OF SMALL OBJECTS.

(*Continued from page* 65.)

It will be seen that the quantity n does not enter into the expressions (*a*) and (*b*) above. Having decided on the optical details of the stereoscope to be used, we can therefore tabulate *print width* and *image width* for various distances x of the stereo image, and these important values can be placed at the worker's disposal. This is done later on. The absence of n shows that the stereoscope does not make itself responsible for the *scale* of the image. This factor in the problem must therefore be introduced into the formulæ by means of the camera lens, to the consideration of which we now pass.

We can arrive at the focal length of the lens required by a convenient back-stairs method of approach, which has the advantage that it enables us to pick up two extremely useful formulæ on the way. If we multiply ratios 1 and 2 together we get: $\frac{\text{print width}}{\text{object width}} = \frac{nf}{x+f}$. Since we have determined that the negatives obtained in the camera are to be suitable for direct printing without magnification or reduction, the ratio just obtained may, for our present purposes, be written: $\frac{\text{negative width}}{\text{object width}} = \frac{nf}{x+f}$.

There is an optical principle, well known to all who use copying apparatus, that if a negative is to bear to the object photographed, say, the ratio m, the *camera extension*, or distance from lens to plate, must be $F(1+m)$, and the *object distance*, or distance from lens to object, must be $F\left(1+\frac{1}{m}\right)$, F being the focal length of the lens about to be used. The ratio m in this case has just been found to be $\frac{nf}{x+f}$. Putting this latter value in place of m we have the two working formulæ:—

(*d*) *Camera extension* $= F\left(1+\frac{nf}{x+f}\right)$.

(*e*) *Object distance* $= F\left(1+\frac{x+f}{nf}\right)$.

These perfectly general formulæ will work out accurately, no matter what may be the focal length of the lens used: and, since n and x are both now included, the distance and scale of the image will be correct. A very wide liberty is thus put in the photographer's hands if he is content with accuracy in these two particulars, as he can use any lens that at all approximates, or even that does not approximate at all, to the correct focal length. Only one lens, however, will render true *depth*, and give an image of perfect form. Depth distortion is not easy to detect unless it is extreme; and if the worker is disposed to commit photographic crimes in the expectation that he will not be found out, the way is open. It is hoped, however, that in such cases he will make confession of his fault, so that the blame may be placed in the proper quarter, and the good name of stereoscopy may not suffer.

It is obvious that the *object distance* given by formula (*e*) above will vary directly with F. But, as stated at the beginning of our present inquiry, the true *object distance* is $\frac{x}{n}$. We have only to equate these two values to find the exact F of which we are in search.

$$\text{Object distance} = F\left(1+\frac{x+f}{nf}\right) = \frac{x}{n}.$$

From which we deduce the formula: $F = \frac{xf}{x+(n+1)f}$.

All these formulæ contain nothing but the photographer's two variables x and n and the stereoscope constant f. If x is taken as some multiple of f they are quite simple in use. In any case, it is only a moment's work to put in the values and find the result.

The first thing we learn from the lens formula just obtained is that when x is finite F must always be less than f, or that it is useless to attempt to get accurate results with a camera lens whose focal length is equal to that of the stereoscope used. It is also seen that as n increases F becomes less, or that higher magnifications of the image require shorter lenses. This is one of the reasons why the stereoscope should not be of unduly short focus. When x is practically infinite, however, as in landscape photography, the formula reduces to the expression $F=f$, and shows that for this kind of work the camera lens and the stereoscope lens should both be of the same focal length.

It will, of course, be impossible to provide a lens of exactly correct length for every value of x and n, but practical accuracy over a wide range of values can be obtained without difficulty. Table I. below, giving values of x, n, and F, is drawn up on very conservative lines, being almost precise, and shows that each lens can cover a considerable group of results.

There still remains one last factor in the problem to be considered. What is to be the separation of the taking lenses, or the extent of the side shift to be given to the camera between the left and right exposures, in order to secure the correct degree of *perspective difference* between the left and the right prints. There is no doubt whatever that this separation or shift must vary inversely with n. The form of the expression laid down at the beginning of our inquiry—*lens separation* $= \frac{S}{n}$—belongs to the demonstrably accurate principles of the investigation. But what value is to be assigned to S? It has been most usefully pointed out that the separation of the eyes is less when looking at an image or object at 12 in. than when looking at infinity distance. In the one case the separation is 2.25 in.; in the other it is 2.5 or 2.6 in. The natural suggestion was made that the *lens separation* should also be less for small values of x, and should widen as the distance increases. There are some theoretical difficulties created by the fact that the eyes are not fixed points in the head, but move from side to side of their orbits as they look from left to right of the image. Nevertheless, the above suggestion, which was adopted by the writer, seems perfectly sound, and may be taken as the safest basis on which to work. The value of *eye separation* for various distances of the image is given in the fourth line of Table I. The figures are merely approximate, and are calculated on the only mathematical basis that presented itself, 2.6 in. being assumed as the infinity separation of the eyes. The worker, therefore, who is being extremely careful to be precise in estimating the value of $\frac{S}{n}$ may leave himself a little liberty as regards the decimal point. He will not be far astray, for higher values of x, as long as the S he works with is not less than that indicated in the Table and not greater than the infinity separation of 2.6 in.

The value of $\frac{S}{n}$ will be very small when n is great, and small errors will have a proportionately greater effect upon the result. On the other hand, when n is fractional, *i.e.*, when the image is to be on a reduced scale, the *lens separation* will become large, and a slight error will not be of importance. In every case care must be taken that no lateral movement is given to the camera. The result of such movement is to make height measurements in the two prints no longer coincide, and to introduce a kind of inaccuracy that is painful to the eyes. In taking the left and right negatives the lens axes must be kept strictly parallel.

We have now reached the end of our inquiry, so far as concerns the problems peculiar to stereo work; but this article would be incomplete as an attempted practical guide if it omitted to consider the depth of focus, or degree of definition obtainable in points of the image lying at given distance before and behind the plane of *image distance* (which we may call the principal plane) in any given case. What stop must be used to secure sharp focus over any desired depth of the image, and what time of exposure will be

necessary? The question becomes pressing for high magnifications at short distances, i.e., when n is large and x small; but the difficulty that then arises is only the ordinary difficulty that attends the photography of solid objects on a scale considerably greater than that of Nature. Stereo photography introduces no new element here and adds nothing to this difficulty. As a definition of what is meant by sharp focus we may adopt the convention that an image at 12 in. is in critically sharp focus when points are represented by diffusion circles of not more than 1/100 in. in diameter, and that as the distance of the image increases the diffusion diameter may also increase proportionately, so that at 24 in., for instance, this diameter may be 1/50 in. This sensible practical convention is generally recognised as theoretically correct. The degree of sharpness it demands is so high that considerably greater diffusion may exist in the more distant points of the image without noticeably injuring definition.

A 1 in. depth of focus also means more than at first appears, since it is 1 in. at each side of the principal plane. A total depth of 3 or even 4 in. will then be in reasonably sharp focus all over if 1 in. of this is on the nearer side of the principal plane and the other 2 or 3 in. on the farther side. The rule will be that to secure critical sharpness as defined above over any given depth d of the image—say for a distance of 1 in. before and behind the principal plane—the effective diameter of the stop used (not its F number) must vary inversely with n and d and directly with x^2. If we double n or d we must halve the stop diameter and increase the exposure four times; if we double x the stop may be four times as wide and the exposure becomes immensely less, though not exactly in proportion to the square of the stop diameter. If we increase x, n, and d proportionately together, i.e., if we magnify the image and project it to a correspondingly greater distance no change will be made as regards the stop diameter, but the exposure will be somewhat lengthened. It follows that for high values of n at 12 or 16 in. either an extremely small stop must be used, involving prolonged exposure, or only a small depth of the image will have sharp definition. For a 1 in. depth of focus pin-hole apertures would be required for the magnifications of 8 and 10 at 12 in. set down near the bottom of Table 1, the stop diameters being respectively .015 and .012. The magnification of 10 at 16 in. would require a stop diameter of .021 for the same depth of focus.

We may give three formidable-looking, but really simple formulæ that will enable the exact scientific worker to calculate in every case the aperture and relative exposure required. It will be seen that here, again, nothing enters into these expressions except the photographer's x and n, and the stereoscope constant f. d represents the required depth or distance of critical sharpness, before *and* behind the principal plane of the image. If this distance is 1 in. on each side of the plane then $d = 1$. It must be kept in mind that a distance d of the image will be represented by a distance $\frac{d}{n}$ of the object. No point of the object should therefore project to a distance of more than $\frac{d}{n}$ at the nearer side of the verticals.

The formulæ as given below are adapted for use in connection with magnified images at short distances, and in all cases where d is small compared with x. When d is taken as an important fraction of x, as may be done in reduced images or in natural size images at a greater distance, the more precise formulæ given in Table II. must be used.

$$\text{Diameter of stop} = \frac{x}{1200} \times \frac{x}{n} \times \frac{1}{d}$$

$$F \text{ number of stop} = nd \times \frac{1200}{x} \times \frac{1}{x + n + 1}{f}$$

$$\text{Effective } F \text{ number of stop} = nd \times \frac{1200}{x} \times \frac{1}{x + 1}{f}$$

We take a simple example to illustrate the meaning of the above terms. An image, viewed through the standard stereoscope, is to be natural size at a distance of 12 in., and is to be critically sharp to a depth of 1 in. Then we have $x=12$, $n=1$, $f=4$, $d=1$. Putting these values in, we find: Diameter of stop = 0.12 in.; F number of stop = 20; effective F number of stop = 25. The stop used will be numbered $F/20$, but the exposure must be calculated on the basis of $F/25$. It is important to notice that these F numbers need not vary, whether the lens used is of correct focal length or not.

(To be concluded.) H. C. BROWNE.

ACCELERATING THE HYPO-ALUM TONING BATH.

ONE of the troubles known to bromide printers is the slowness of action which is often exhibited by hypo-alum. True, this is not one of those things which are regular and unalterable. It is possible, and in places common, for the process to be carried out rapidly and without delay, day after day, but in many cases the length of time taken up by toning is much more than it need be, and in few cases could one guarantee beforehand that only a few minutes would be so absorbed.

At a time when I personally handled large batches, I often found myself going home on the 8.30 when I should have been on the 6.15, merely because the toning bath had displayed a persistent reluctance to get going, or having got going, had been so slow in carrying on. Naturally, this gave me to think, but at the time I could devise no remedy. Recently, my attention was called to a case of slow toning which was unusually slow, and having a few moments to spare, I put to test a theory that I had evolved previously.

In the case in point, the bath was fairly good and was at a sufficiently high temperature, nevertheless the prints, a dozen half-plates, had stood it for an hour without sign of change. Leaving them in, with the heat still on, I prepared two dishes of solution and collected a comprehensive pile of old black and white prints from the waste bag. Some were bromide, some gaslight; some over- and some under-exposed. One of the solutions was plain saturated hypo; the other, sulphuric acid of a strength of 1 in 14. I do not say either of these is ideal for the purpose; they were experimental. I soaked the old prints in the hypo until limp and then transferred them to the acid, turning each over for a couple of minutes in order to give the acid opportunity to penetrate the hypo-laden gelatine everywhere. In neither dish was the action carried on to the point of reduction of the image. From the acid bath, after a slight rinse, the prints were transferred to the hot toning bath where they toned out a good sepia in about three minutes, being fully toned and in the wash-water when the half-plate prints were just starting to turn colour.

Apparently my theory was sound, though I have other trials and experiments in view to support and prove it, if possible. My idea was this. I knew that the toning depended on the action of the precipitated sulphur in the bath, and that before this could act it had to come in contact with the silver. That its action was not reluctant I knew by the state of silver coins in my trouser pockets in the days when I constantly handled the stuff. Therefore, something must obstruct, and as sulphur is not soluble, what more likely to obstruct its passage to the silver than gelatine. I had noticed that when prints were fixed in a fresh mixture of hypo and alum without acid (a very dubious fixing bath for anything but prints for toning) they were apt to tone rapidly, and that when some prints were experimentally put through a sulphuric stop bath, they toned themselves after fixing. This could only be due to sulphur in the gelatine.

By soaking prints with hypo, sulphur (in soluble combination) is put into contact with the silver, in the structure of the gelatine. When the hypo is met by sulphuric acid, sulphur is precipitated in a nascent form and still in contact with the silver. Hence the expectation of rapid toning on the application of heat.

In practice, it would seem easier to transfer prints straight from the fixing bath to the acid, and if the fixer was plain hypo this would be all right, but in the case of the numerous compound fixing baths other actions might take place. Thorough washing, however, should not be necessary at any stage. After immersion in acid it might be that hot water would finish the action, but this would be risky to the gelatine, and if sufficient sulphur had not been precipitated in the film the action would stop short. With the process as I have described it, it is feasible to suppose that the sulphurisation by the "internally precipitated" sulphur may make way for the action of sulphur in the hypo-alum solution, and thus the two together complete the toning. In any case, as far as I have gone, the action is decidedly more rapid when precipitation has taken place in the film itself.

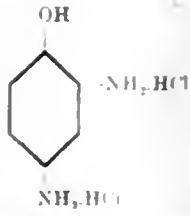
Whether the hypo and sulphuric baths prevent "staining"—the appearance of blue-black patches which refuse to tone—or not, I cannot say. I am awaiting a stained print to see what the double immersion will do. If such staining is due to "cooked" gelatine, as some have asserted, it may be that hypo-alum cannot work purely on account of inability of the sulphur to penetrate the cooked parts of the film, in which case internal precipitation would soon wipe off the "stains," and incidentally save much temper. THERMIT.

THE STABILISING OF SOLUTIONS OF AMIDOL.

PHENOLIC bodies containing two or more hydroxyl groups in the molecule very readily oxidise in alkaline solution. Thus pyrogallol dissolved in dilute sodium or potassium hydrate solution rapidly absorbs oxygen from the air and becomes very dark brown owing to the formation of a deep-coloured dyestuff.

With the mild alkalis like sodium carbonate this action is much less rapid, but still takes place. The tendency to darken and thus become useless from a photographic point of view, is generally overcome by making a stock solution of pyrogallol, and only adding the alkali immediately before use.

Amidol, which is a di-hydrochloride having the formula :—



needs no alkali for it to act as a developer, and thus the problem of stabilising this substance is simple.

According to Bunel (Bull. Soc. Franç. Phot., 1921, *8*, 290), a small amount of lactic acid considerably reduces the rate of oxidation of amidol in air, and does not affect its developing power. The amidol solution he used was the usual one, namely.

Amidol	...	5 grams
Anhydrous sodium sulphite	...	30 grams
Water to	...	1,000 c.c.

To this 5 c.c. of lactic acid of specific gravity 1.21 was added. After seven weeks the solution showed scarcely any colour, although the bottle had been periodically opened for use. Glycerine, which retards the oxidation of sulphites, might be expected to behave similarly to lactic acid towards the oxidation of amidol, but here it shows no retarding influence. According to Bunel, glyceric acid acts in the same way as lactic acid.

The reason for this is probably a structural one. The graphic formulæ of these three substances are

CH_2OH	CH_2OH	CH_3
$CH.OH$	$CH.OH$	$CH.OH$
CH_2OH	$COOH$	$COOH$
Glycerine.	Glyceric acid	Lactic acid

Desalme (Rev. Franç. de Phot., 1921, *2*, 128) has used a solution which he terms "stannous tartrate" for stabilising amidol solutions.

The "stannous tartrate" solution was made by dissolving 5 grams of stannous chloride and 7 grams of tartaric acid in 30 to 40 c.c. of water. This solution was added to one containing 30 grams of sodium carbonate crystals in 30 c.c. of water. The total volume was made up to 100 c.c. This solution is stated to have no action on silver bromide or on the latent image. For use with amidol it is first acidified with sodium bisulphite, but this worker does not specify the quantity of the bisulphite to be added.

Lobell (Bull. Soc. Franç. Phot., 1921, *8*, 291) has compared the efficiency of Bunel's and Desalme's solutions for stabilising amidol developers by means of the Eder Hecht sensitometer, using bromide paper of constant exposure. Development was always sufficiently prolonged to reach γ^{∞}. It was found that the developing power is retained approximately twice as long in developer containing either stabiliser, as in the ordinary amidol developer.

It is now found, however, that amidol prepared from 2 : 4 dinitro-phenol by reduction with tin and hydrochloric acid already contains small quantities of tin chloride, and thus in solution with sodium sulphite contains its own stabiliser. Advantage has been taken of this fact in a Provisional Patent Specification (No. 2,070).

The reaction involved in the reduction of 2 : 4-dinitro-phenol to the diamino-compound may be expressed :—

$$HO.C_6H_3(NO_2)_2 + 4Sn + 16HCl =$$
$$HO.C_6H_3(NH_2)_2 + 4SnCl_4 + 4H_2O.$$

The amidol so formed could unite with the stannic chloride simultaneously produced. If excess of tin be employed in the reaction, stannous chloride would be produced instead of stannic chloride : thus :—

$$HO.C_6H_3(NH_2) + 8SnCl_2 + 4HCl + 4H_2O.$$
$$HO.C_6H_3(NH_2) + 8SnCl_2 + 4H_2O.$$

Stannous chloride, like stannic chloride, could form a double salt with amidol. These double compounds have the formulæ :—

$HO.C_6H_3(NH_2)_2$, H_2SnCl_4,

Amidol stannochloride, and

$HO.C_6H_3(NH_2)_2$, H_2SnCl_6,

Amidol stannichloride.

A developer made up from amidol containing amidol stannochloride (only a trace) has shown excellent keeping qualities. No darkening has occurred at present after the lapse of five months.

J. G. F. DRUCE, M.Sc., A.I.C.

FORTHCOMING EXHIBITIONS

February 7 to 11.—Sheffield Photographic Society. Particulars from the Hon. Secretary, James R. Wigfull, 14, Parade Chambers, Sheffield.

February 11 to 25.—Scottish Photographic Salon. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, "St. Denys," Bellevue Road, Exmouth.

February 18 to March 3.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Latest dates: Entry forms, February 15; exhibits, February 23. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 20.—Welsh Salon of Photography. Latest date for entries, March 9. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 16 to 18.—Leytonstone and Wanstead Camera Club. Latest date for entries, February 28. Particulars from the Secretary, S. W. Liddell, 20, Fillebrook Road, Leytonstone, E.11.

March 27 to April 3.—Dennistoun Amateur Photographic Association. Latest date for entries, March 11. Particulars from the Exhibition Secretary, Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Scott, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 20, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair, Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 15 to October 28.—Royal Photographic Society. Latest date for entries to carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

A PHOTOGRAPHER'S WILL.—Among the wills proved last week was that of Mr. Charles W. Burrows, of Fitzroy Street, St. Pancras, who died on December 24 last, £10,156.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications January 23 to 28 :—

DAYLIGHT DEVELOPMENT.—No. 1,961. Daylight developing-tank for photographic films. F. H. Ibbetson.

SHUTTERS.—No. 2,485. Combined roller-blind and focal-plane photographic shutter. W. H. Lambert.

TELEPHOTOGRAPHY.—No. 2,212. Telephotography. D. Mihály.

PHOTO-MICROGRAPHY.—No. 2,502. Photo-micrographic apparatus. M. T. Denne.

STEREOSCOPY.—No. 2,381. Method of producing stereoscopic phenomena and eliminating distortion in optically projected pictures T. E. R. Phillips.

COMPLETE SPECIFICATIONS ACCEPTED.

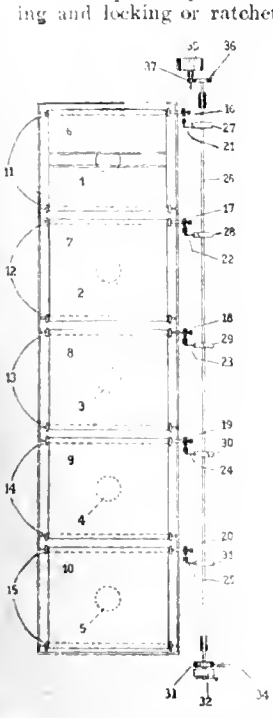
These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CAMERA FOR RECORDS OF RACE FINISHES.—No. 152,287 (October 9, 1919). The invention relates to a device for photographically fixing the position of runners, race horses, vehicles on a race track with relation to each other and to the winning post at the moment of passing the same, and is intended to assist racing judges in their decision as to the winner and to the sequence of the participants in the race that pass the winning post after him.

Several cameras with independent shutters are arranged at the winning post in such a manner that the axes of their objectives are in one plane, which is perpendicular to the race track, the shutters of the several cameras being interconnected in such a manner that they can be released in pre-determined succession at the moment when the competitors arrive at the winning post.

In the drawing the lenses 1—5 situated in front are shown dotted, the shutters arranged in front of the plate are marked by the numbers 6—10. The shutters pase over pairs of rollers 11—15 respectively. Each of the rollers is provided with a winding and locking or ratchet gear device 16—20 respectively. This locking device comprises locking parts which in the drawing are shown as simple pawls 21—25 respectively. Opposite these pawls is arranged a cam shaft 26. On the same are mounted cams 27—31 in a staggered order, so that when the cam shaft 26 is rotated, the cams 27—31 come successively into engagement with the pawls 21—25 respectively. According to the degree of relative position of the same cams on the circumference of the cam shaft 26, and according to the speed of rotation of the shaft 26, the time interval between the release of the movement of the single shafts 16—20 of the roller shutters 6—10 is greater or smaller. In the drawing the cam 27 is shown in engagement with the pawl 21. The pawl 21 is therefore no longer in engagement with the ratchet wheel 16, the shutter 6 is already in motion, and is at the moment in front of the centre of the plate. When this shutter 6 has travelled its distance, the cam 28 will have reached the pawl 22, and the second shutter will become operative, and so on. Of course, with a particularly uniform setting of the cams it is possible to obtain such a quick sequence of the single photographic operations that the last shutter has already begun its movement before the first one has completely finished it. The rapidity of sequence of the single shutter openings is therefore an unlimited one. The shaft 26 is controlled by a spring mounted in the casing 32. A ratchet wheel 33 and a pawl 34 are intended for the tension, locking and release of the shaft 26. The pawl 34 can be operated either by means of pulling a stretched string, or by an electromagnet or the like. When the movement of the racing object is particularly fast, and the moment at which the winning post is passed, is therefore more particularly difficult to catch, it is advisable to make the time sequence of the single instantaneous shutters not too quick, and it then becomes necessary to brake the speed of rotation of the cam shaft 26. To that end is provided for instance a fly 35 coupled to the cam shaft 26 by means of a toothed wheel gear 36, 37. Of course, instead of a fly wheel some other braking mechanism could be provided for the cam shaft 26. By exchanging the wheels or by using flies 35 of different size, the speed of rotation of the shaft 26 can be modified at will.



The process of photographing during the passage past the winning post is as follows :—

The apparatus is placed in the plane of the winning post, so that all its lenses are in one and the same plane. The shaft 26 is set by turning, and the single shutters are also set and the ratchet gear parts 16—20 and 21—45 are brought into the ready position. The plates are then uncovered, and the apparatus is ready for photographing. Immediately in front of the winning post, at a distance which according to experience is smaller than the space covered by the racer in the time interval during which takes place the release of the first and last shutter, is provided a sight, and at a suitable distance from the apparatus the operator entrusted with the releasing takes his position, so that the line of sight is laid in a certain section of the race track in front of the winning post. The operator has to concentrate his attention on the moment in which the horses or runners or vehicles pass the line of sight. At this moment he renders the ratchet gear part 34 inoperative, the shaft 26 rotates and the shutters 6—10 begin to run. If the distance of the line of sight from the apparatus is correctly determined, the shutter 8 opens at the moment when the winner passes the post. If the operator committed a slight error, one of the shutters opening earlier or later seizes the correct moment.

By means of the known processes for quick development of the picture, the result can be shown in the picture so quickly that in case of any doubt the decision of the judge can be postponed without delaying the racing to an undesirable extent.—Optische Anstalt C.P. Goerz Aktiengesellschaft, 45/46, Rheinstrasse, Friedenau, Berlin.

RELIEF PRINTS.—No. 172,342 (June 4, 1920). Several processes have been proposed for converting photographs on silver salt colloid sheets into reliefs. For instance, by treating them with a solution of a chromate alone or mixed with a ferri-cyanide or a copper salt, reliefs are formed which are insoluble in warm water but do not coincide exactly with the silver photograph because the tanning goes beyond the silver limits and therefore close lines are liable to be merged into each other. For the same purpose the known property of pyro ammonia developers to harden gelatine containing silver was tried, but the disadvantages appeared even more marked and the whole gelatine sheet often became insoluble during development.

By the present invention the oxidation products of the polyhydroxybenzenes in the developer are used to effect a hardening of the colloid, it having been found that these products will produce a hardening which exactly coincides with the silver image and corresponds with its intensity. It is essential that but little or none of the usual preserving agent should be present in the developer, so that the generally used sulphite is to be omitted or used only in very limited proportion, that is to say, in proportion not exceeding half the weight of the polyhydroxybenzene. It is also essential that the necessary alkali should not be ammonia and that when an alkali carbonate is used, generally potassium carbonate, the quantity present must not be in so large a proportion that it prevents the photographic film from swelling, that is to say, its proportion should not exceed about 10 times the weight of the polyhydroxybenzene.

The hardening developer may be used with addition of a non-hardening developer or a reducing salt.

Instead of developing the latent silver image by a developer that has a tanning action, a non-tanning developer may be used first, and then after elimination or not of the reduced silver and after having exposed the sheet to light a tanning developer may be applied. Naturally, in this case there is an inversion of the image.

When the sheet which has been exposed through the support

or exposed from the front and then, after development, detached from the support and transferred in inverse sense to a support, has been hardened at the places constituting the image, the parts remaining soluble are removed. For instance, when gelatine is the colloid the sheet requires merely to be treated with warm water. The relief may be treated in any known manner, for instance, it may be dyed. Also the sheet may be dyed previously, or dyes or pigments may be added to the emulsion.

Suitable developers for the purpose of the invention are, in parts by weight :—

(1)	Pyrocatechin	2 parts.
	Potassium carbonate	15 ,,
	Water	100 ,,
(2)	Hydroquinone or bromo-hydroquinone (adurol)	2 ,,
	Sodium sulphite	0.5 part.
	Potassium carbonate	15 parts.
	Water	100 ,,
(3)	Pyro	2 ,,
	Sodium sulphite	1 part.
	Potassium carbonate	15 parts.
	Water	100 ,,
(4)	Pyro	2 ,,
	Methyl-aminophenol (metol)	0.2 part.
	Potassium carbonate	15 parts.
	Water ... •.	100 ,,

In order to control the action of light during the exposure it may be advantageous to use sheets containing compounds which absorb actinic rays.—Arthur George Bloxam, 30, Southampton Buildings, London, W.C.2, for Actien-Gesellschaft für Anilin fabrikation, Berlin, S.O. 36.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER

The following marks have been placed on the register :—

VITTEX.—No. 408,883. Photographic printing paper and postcards L. Gevaert & Compagnie, 23, Sente Straat, Vieux-Dieux, Belgium, manufacturers of photographic materials

TRADE MARKS REMOVED FROM REGISTER

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is, of course, the method adopted by a firm having no further occasion for the use of a mark.

ROCKET.—No. 175,487. Elliott & Son. Registered in 1893 in Class 1.

DRUX (Device).—No. 175,481. Compagnie Française de Papiers Photographiques (Société Anonyme). Registered in 1893 in Class 39.

PHOTOPHANE.—No. 295,381. A. H. Cooper, trading as the Photophane Co. Registered in 1907 in Class 39.

KOH-I-NOR.—No. 295,646. Photochemische Fabrik Roland Risse Gesellschaft mit Beschränkter Haftung. Registered in 1907 in Class 39.

ANGELO.—No. 296,599. Eastman Kodak Co. Registered in 1907 in Class 39.

EURYSTIGMAT.—No. 297,772. The London Stereoscopic and Photographic Co., Ltd. Registered in 1907 in Class 8.

ALBUMET.—No. 297,799. Vereinigte Fabriken Photographische Papiere. Registered in 1907 in Class 39.

REGISTRATIONS RENEWED.

C. URBAN.—No. 297,639. The Natural Colour Kinematograph Co., Ltd. Registered in 1907 in Class 8

V. M. C.—No. 297,670. W. E. Henry, trading as The Vanguard Manufacturing Co. Registered in 1907 in Class 1.

DUCAR.—No. 297,874. The firm trading as Carl Zeiss. Registered in 1907 in Class 8.

DOLMI.—No. 298,211. Kodak, Ltd. Registered in 1907 in Class 1.

TEXO.—No. 301,114. Kodak, Ltd. Registered in 1908 in Class 39

ARTURA (Label).—No. 299,215. The Artura Photo. Paper Co. Registered in 1908 in Class 39.

TENAX.—No. 299,170. Optische Anstalt C.P. Goerz Aktiengesellschaft Registered in 1907 in Class 8.

New Materials.

PANEL PHOTETTES. A new style of the "statuette" cut-out photograph mounted on wood has been introduced under this name by Mr. A. Smith, 107, Melbourne Grove, East Dulwich, London, S.E.22. Essentially the novelty of the introduction lies in the mounting of the cut-out portrait on a panel of dark wood provided with a hinged strut. The statuette effect is thus exhibited in a striking way by contrast of the tones of the outline photograph against the dark wood background, and we can readily believe that the "Panel-Photettes" have been warmly welcomed by photographers looking for an attractive novelty for their windows and show-cases. Mr. Smith who has had a long experience in fret cutting and is a maker of cut-out statuettes for other trades, evidently is a master in the making of these goods. We notice that the wood on which the photograph is mounted is cut at a sharp angle, so that the photograph may be looked at from almost any position without showing the section of the wood. The latter, moreover, is blacked as a further precaution. Particularly for full-length portraits of children the style is exceedingly attractive. Mr. Smith issues the "Panel-Photettes" in a great many shapes at prices which are approximately 2s. 6d. in postcard size to 6s. for 12 x 10. We can advise any photographer, who requires an attractive exhibit for his window and one which will bring other orders, to make the experiment of placing a trial order for one or two of these novelties.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 7, the president, Dr. G. H. Rodman, in the chair.

A paper on "The Application of Flashlight Photography to the Study of Natural History Subjects" was read by Mr. Oswald J. Wilkinson, whose flashlight photographs of Nature subjects received the Society's medal at the last exhibition.

Mr. Wilkinson reviewed the applications of flashlight to Nature photography which had been made by the Keartons and Mr. Radclyffe Dugmore, and showed a photograph of a lion in his native habitat taken by Mr. Cherry Kearton in Africa. He passed on to describe his own experiments in obtaining photographic records of moths, larvæ, spiders and similar small subjects at night by flashlight. He was accustomed to work with the camera set at an extension of about double the focal length of the lens, so as to give approximately same size reproductions. The camera was thus about 12 inches from the subjects. The flash powder was likewise placed at about this same distance. With a lens aperture ranging from *f*/22 to *f*/32 (it was not clear whether nominal or effective), and with a Wellington Anti-screen plate exposed through a K 1 filter, the quantity of flash powder (Johnson's Professional) ranged from 30 to 60 grains. Mr. Wilkinson showed numerous lantern slides, the full gradation and detail of which afforded ample evidence of the full exposure obtained under these conditions. He referred to the great necessity of keeping the flash powder dry. He had chiefly used a touch-paper method of firing, but was convinced that an electric firing method was essential in order to make the flashlight method of general usefulness in Nature photography, since, in many circumstances, it was necessary to fire the flash immediately a subject had come into position.

Mr. Wilkinson also showed a series of Paget colour transparencies of butterflies, photographed same size by flashlight, again by burning the flash powder a few inches away from the subject. A short discussion followed, in which Messrs. E. J. Bedford and Hugh Main referred to the value of flashlight methods in photographic Nature study, and paid a tribute to the correctness of colour rendering of Mr. Wilkinson's Paget transparencies.

Mr. A. C. Banfield suggested that a matt parabolic reflector might be used as a combustion chamber for the flash powder, and would greatly reduce the quantity of powder required. As a protection of the flash powder against damp in outdoor work, a very simple plan was to make a few bags of tissue paper dipped in solution of celluloid dissolved in amyl acetate. The flash powder would keep dry in such capsules, and, moreover, was instantly fired by any of the usual methods of ignition.

On the proposition of the chairman, a most hearty vote of thanks was accorded to Mr. Wilkinson for his lecture.

CROYDON CAMERA CLUB.

Certainly one of the most "wonderful evenings," in the words of a member, was afforded last week, by Mr. C. P. Crowther, F.R.P.S., with his sensational divertissement, entitled "Portraiture with a Portable Light," helped by the lively environment.

A strong counter-attraction was also provided in the comely shape of an exceedingly fair young lady—Miss Dorinea Shirley, specially released for the occasion from that stage where the star ultimately twinkles many times a second on the screen. Lady visitors are so unusual that the kindly "office boy" vacated his usual seat for one contiguous, ostensibly for the purpose of protecting the fair one from the blandishments of the president. This tale, however, fell flat.

To report Mr. Crowther adequately would be an extremely difficult task, it being almost impossible for printers' ink to reconstruct the ethereal atmosphere created. Actualities are always subordinated to sentiment, and a rushing enthusiasm, and poetic flow of ideas, hypnotizes cold judgment for the time being. But it cannot be gainsaid never was a lecture listened to more attentively at Croydon, though primarily intended for professional photographers, and the stirring appeal made for all to take a pride in their art and strive for better things can never fail to influence but in the right direction. Scathing, but absolutely true was a brief allusion to the smug self-complacency exhibited by not a few artists of the camera concerning their own work, standing out in painful contrast to the attitude adopted by their brethren wielding the brush. Additional weight also attached to Mr. Crowther's remarks, as he can not only give good advice but deliver the goods, even if they may be rather strong meat for a conservative general public apt to resent innovation.

When dealing with faces delineated as a map, or (preferably) otherwise, he approached Mr. Inskeep, and after regarding him steadfastly convulsively hid his own face with his hands. "Well, you need not be so aghast, for it is not a bad dial as dials go," tartly commented the office boy. From that moment war was declared, and throughout the evening, at intervals, the unfortunate official was badly mauled, it being almost impossible for him to get in a word edgeways in self-defence.

Turning to the main theme of the evening, that of "intimate photography," all depended upon getting *en rapport* with the sitter. Even on occasion he had employed such terms as "my dearest" or "my darling" to achieve the desired end, a procedure, it may be remarked, however safe it may be for married men with the artistic temperament, is fraught with grave peril to the bachelor operator.

Associated with this "intimate photography!" was a near viewpoint necessitating a comparatively short focus lens. Mr. Pirie Macdonald (who was often quoted), he said, largely uses a lens of

12½ ins. focus on 10 by 8 plates, the prints being trimmed to 9 by 6. He had also told the lecturer that it had taken him 2½ years to master the focus of this lens. No details of the prolonged combat were given, but the incident shows the danger of allowing a fierce focus of this size to get out of hand. Many present must have resolved to use nothing but vest-pocket cameras in the future.

Frequently Mr. Crowther had employed a 15-in. lens on a 12 by 10 plate, avoiding distortion by "over-focussing" (apparently on a point in advance of the sitter). Ordinarily, however, he focussed on a point midway between the eyes and the nose. Much emphasis was laid on the importance of subordinating the ears which over-focussing achieved. Equal stress was laid on the necessity of a good rendering of the hands.

A set of superb portrait studies, by Mr. Crowther, were next shown on the screen, all taken with a practically point source of illumination diffused as required, the shadow side being lightened by reflectors when necessary. The orthodox angle of illumination, 45 deg., was strongly recommended. A set of really splendid Paget colour slides followed, particularly good being some low-toned reproductions of pictures.

A portable apparatus for home portraiture when electric light is available, recently put on the market by Messrs. Marion's, was then erected, and members set gaily to work with the young lady visitor as the willing victim. A large hat, whose capacious brim afforded support to straggling things simulating a shimmering waterfall necessitated the illuminant being brought low. So will the sitter, probably, if ever she sees the results, for the lecturer admitted it was very difficult indeed to get under that hat. As a matter of fact no member had the audacity to attempt it.

Mr. Crowther said he was no electrician, but correctly advised the use of large candle-power gas-filled lamps, owing to the higher temperature of the filament, and greater actinism of the light compared with lamps of more moderate candle-power. Unfortunately the former tended to blow the fuses on ordinary household circuits.

In this connection, and writing subject to correction, branch circuits are designed to carry three ampères and upwards. True, a 2,000 c.p. 200 volt, and a 1,000 c.p. 100 volt lamp, take five ampères, yet overloading the circuit for a short time to this extent will do no harm if a stouter fuse be temporarily employed, and care be taken that no other lamps on the circuit are running. Anyway, the production of a lamp of maximum illumination, which can be safely used alone on household circuits, if not already on the market, ought to be. It would far surpass in efficiency the four moderate candle-power lamps employed by Mr. Crowther. In all other respects the apparatus appeared admirably adapted for home portraiture, and, excluding the lamps, folded into a surprisingly small compass.

The discussion was a discussion with a vengeance, and can only be touched upon. Mr. Salt agreed that it was desirable for photographers to unrut themselves, but if all adopted the "artistic style," for want of a better term, another rut would be fashioned. They could then revert to present-day practice. Very short focus lenses undoubtedly had their uses when camera and operator necessarily were brought close to a fascinating sitter, but otherwise he preferred a long focus lens for reasons well-known.

Mr. Catharine modestly pointed out that as he and Mr. Pirie Macdonald largely went in for "head and shoulders," they were both much on the same level. Mr. Catharine then passed on to a critical examination of the distance *expressed in feet*, which in the print apparently separated nose and ears in the "intimate photography" system, during which Mr Crowther afire began slowly to approach the speaker, who not liking the look of things backed into some cameras, and was forced to sit down.

Mr. Handel Lucas severely chided the lecturer for leading the tyro straight into impressionism. Noble sentiments on an elevated plane then flowed freely from Mr. Jobling, who throughout preserved a happy smile, which ill-harmonised with the solemnity of the subject. The president, Mr. John Keane, in proposing a vote of thanks, which was carried with much acclamation, very truly said that the enthusiasm of the lecturer had undoubtedly proved infectious. General verdict—an altogether O.K. evening.

Glasgow and West of Scotland Society of Professional Photographers.—The monthly meeting of the above Society was held on January 27, in Mr. Bairnfier's Studio, Sauchiehall Street, Glasgow, when there was a good turnout of the members. The subject for the evening was "Print Criticism." Prior to the date of the meeting members were asked to submit prints for criticism, and the keen interest of the members in the work of the society was shown by the large number who sent in samples of their work. The critic appointed by the Society was Mr. E. Drummond Young, of the Edinburgh College of Art, whose criticism was most interesting and instructive, and very much appreciated by all the members present.

Herefordshire Photographic Society.—At the annual meeting of the Herefordshire Photographic Society, held at 76, Eign Street Hereford, on Monday evening (January 30), a number of new officials were elected, and there seemed to be a general desire for a reconstructed programme. A keener spirit was shown than for several years past, and the Society's future, therefore, is looked upon with interest. Mr. Alfred Watkins, F.R.P.S., who has been president for a number of years, expressed a desire to vacate office, on account of health reasons, in favour of someone else, and his resignation was received with much regret and sincere thanks for his past services. It was decided to ask Mr. J. S. Arkwright, who has taken a great interest in the Society, to become president, and the following were elected vice-presidents: Mr. Alfred Watkins, Mr. John Parker, Mr. W. J. Humfreys, Mr. W. C. Gethen, Mr. Ernest Davies, Mr. S. Beeson, Dr. Day, Mrs. G. Leigh Spencer, Mr. A. G. Turner, Mr. S. Roberts, M.P., and Mr. C. T. Pulley. On the management committee were appointed Mr. W. Williams, Mr. W. W. Robinson, Mr. W. A. Grosvenor, Mr. H. E. Pile, Miss McAdam, Mr. Best, Mr. Ernest G. Davies, Mr. McKaig, Mr. Carter, Mr. Copeland, Mr. A. Livesey, Mr. Walter Pritchard, Mr. S. Beeson, and Mr. Brooke. Mr. A. Livesey was thanked for his kind services as hon. secretary and treasurer for the past seven years, and his office was undertaken by Mr. Godfrey Davies, 7, Eign Street. Mr. W. J. Davies was reappointed librarian, Mr. S. Beeson lanternist, and Mr. A. C. Slatter auditor. It was resolved to hold meetings on the second Friday in each month.

Commercial & Legal Intelligence.

NEW COMPANIES.

Stead and Co., Ltd.—This private company was registered on January 26, with a capital of £1,500 in £1 shares. Objects: To take over the business of a drug store keeper, photographer and photographic dealer carried on by Annie M. Huband, at 23, Duke Street, Brighton, as "Stead and Co." The first directors are: C. J. Huband, 11, Clarence Square, Brighton (permanent managing director and chairman); Mrs. A. M. Huband, 11, Clarence Square, Brighton; F. W. Fowles, 8, Richmond Place, Brighton. Registered office: 23, Duke Street, Brighton.

Latters, Ltd.—This private company was registered on January 30, with a capital of £1,000 in £1 shares. Objects: To carry on the business of retailers, merchants and compounders of, dealers in and agents for the sale of all kinds of chemicals, and manufacturers of and dealers in chemicals, toilet requisites, photographic cameras, lenses, plates, films, etc. The first directors are: C. C. Lever, Little Bekkons, Beaconsfield, Bucks; W. H. Lessiter, 80, Hunsdon Road, New Cross, S.E.14. Qualification: £50. Remuneration as fixed by the company. Secretary: C. C. Laver. Registered office: 46a, St. George's Road, S.E.1.

Coloured Blue Prints.—According to a German patent, No. 341,735, of February 15, 1921, abstracted in the "Journal of the Society of Chemical Industry," the Dürener Fabrik. Phot. Papiere Renker und Co. add a red or orange dyestuff, such as azo yellow or benzo fast red G, to the sensitising solution of ferric ammonium citrate and potassium ferricyanide, or to the paper before sensitising. The resulting prints have coloured lines on a blue ground. The green tone which an ordinary blue-print assumes on long keeping is changed by the complementary action of the dye to white. By selection of the dyestuff so as to obtain the same transparency to actinic rays for the lines and the background fraudulent copying of such prints is prevented.

News and Notes.

PHOTOGRAPHY ON RAMSGATE SANDS.—In the published list of fees payable for sand "pitches" at Ramsgate during the present year appears the following: "Photographing bathers, £100 each." Hiring out donkeys is only £35.

BRUSSELS COMMERCIAL FAIR.—The third commercial fair, organised by the Brussels Municipality, is to be held from April 3 to 19. Photography and cinematography form Section 33. Particulars of charges for exhibition space, etc., are obtainable from 19, Grand Place, Brussels.

ROYAL INSTITUTION.—On Thursday next (February 16), at three o'clock, Professor Arthur Perkin begins a course of two lectures at the Royal Institution on "Dyeing: Ancient and Modern," and on Saturday (February 18), Professor Ernest Gardner delivers the first of two lectures on "Masterpieces of Greek Sculpture."

KORISTKA OPTICAL APPARATUS.—The City Sale and Exchange inform us that they have been appointed sole British agents for the Koristka Optical Co., of Milan, makers of microscopes, photographic objectives and other optical apparatus. Abridged catalogues are obtainable on application to 81, Aldersgate Street, London, E.C.1.

TELEPHOR LONG-DISTANCE PHOTOGRAPHY.—A message from Budapest gives details of the invention of a young Hungarian engineer, which has aroused much interest in Paris. The inventor (says Reuter) has constructed an apparatus named the "Telephor," which it is claimed enables photographers to see and to photograph objects far away.

DENNISTOUN AMATEUR PHOTOGRAPHIC ASSOCIATION.—The Society's exhibition will be held from March 27 to April 8. There are two open classes, one for prints and the other for lantern slides. Mr. James McKissack will judge, and the latest date for the receipt of entry form and exhibits is March 14. Particulars and entry form from Mr. Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

THE PENROSE PROCESS POCKET BOOK.—The pocket diary issued by Messrs. Penrose is of convenient narrow and slim form for the waistcoat pocket, and contains numerous optical and chemical formulæ and tables of special interest to photo-engravers, as well as a comprehensive series of tables for the ready reckoning of areas and prices of blocks. Messrs. Penrose issue it at the price of 2s. 6d.

CRIPPLEGATE AND HACKNEY EXHIBITIONS.—Arrangements have been made by which exhibits entered for the exhibition of the City of London and Cripplegate Society's exhibition will be transferred to the Hackney Society, whose exhibition opens a fortnight after the closing of that at the Cripplegate Institute. Exhibitors who wish to take advantage of this arrangement are asked to notify their desire on both entry forms.

CAMERA SMUGGLING AGAIN.—A Mr. Jean Sauvnani had to pay £54 15s. 6d. at the Dover Police Court last week for smuggling articles, including binoculars, opera glasses and a camera. The goods were not declared, and were discovered wrapped up in different pieces of underclothing. The camera he had brought from Germany for his wife. The Customs officer asked that Mr. Sauvnani should pay the full penalty, as he was a constant traveller to the Continent. Double value was exacted and the goods confiscated.

FLASHLIGHT PHOTOGRAPHY.—Messrs. Johnson & Sons, 23, Cross Street, Finsbury, London, E.C.2, have just issued an eight-page booklet of instruction in flashlight work, illustrated with a number of reproductions of photographs showing the many attractive subjects, for at-home photography during the winter months. Occasional professional users of flashlight will appreciate the exposure tables giving the quantity of powder which should be used according to the distance of the flash from the subject, speed of plate and aperture of lens. The booklet is obtainable free on application.

ROYAL PHOTOGRAPHIC SOCIETY.—At the meeting arranged by the Scientific and Technical Group for Tuesday next, February 14, two papers by Professor The Svedberg will be read, one on the relation between sensitiveness and size of grain in photographic emulsions and the other on the reducibility of the individual halide grains in a photographic emulsion. A paper by Dr. S. E. Sheppard and A. P. H. Trivelli dealing with Professor Svedberg's method of grain analysis will also be read; and Mr. K. C. D. Hickman will describe an optical method of testing washing appliances and will give a demonstration of some washing devices.

"A MAGISTRATE-PHOTOGRAPHER."—With reference to a note under this heading on page 69 of our last week's issue. Before any evidence was called at the resumed hearing of the case last Friday the chairman of the magistrates referred to the matter saying: "A statement has been made by several newspapers that at the last hearing a magistrate sitting on the bench took a photograph of Major Armstrong in the dock. The magistrate in question was not a member of the bench, but by courtesy occupied a seat at the back of the sitting magistrates. While the magistrates had retired to consider a point of law, the magistrate in question took advantage to use his camera. This bench is very much annoyed at the fact, and they would not have permitted it for a moment if they had known such a thing was going to happen. I think it is a great liberty, and a great want of taste on the part of the gentleman in question to have done such a thing." The matter then dropped.

PHOTOGRAPHIC MATERIALS FOR EGYPT.—The Department of Overseas Trade is informed by His Majesty's Commercial Agent for Egypt that the Ministry of the Interior, Egypt (Personnel and Equipment Department, Supplies Office) has invited tenders for the supply of photographic material for the year 1922, which will be received by the Director, Personnel and Equipment Department, Ministry of the Interior, Cairo, not later than noon on March 15. The photographic material required includes apparatus and accessories, chemicals and plates and papers. A copy of the conditions of tender is available at the offices of the Department of Overseas Trade (Room 53), 35, Old Queen Street, London, S.W.1, for inspection by interested United Kingdom firms, while an additional copy is available for transmission to provincial firms unable to arrange for inspection in London. Local representation is an essential condition of tendering, and the Department will be pleased to suggest to United Kingdom firms not already represented in Egypt the names of British houses established in Egypt through whom tenders might be submitted.

DECADENT PRESS PHOTOGRAPHY.

To the Editors.

Gentlemen,—Permit a humble reader like myself to congratulate you upon your plain-spoken note on the decadence of press photography and the lamentable position of the art to-day—as represented by the picture papers.

You are by no means alone in your opinions, for a contemporary ("The Bazaar, Exchange and Mart") said some very outspoken things a few days before your comments appeared. Said the "Bazaar": "Taking up any illustrated paper . . . you can at once see what subjects the editor considers to be of the greatest interest, and you are pretty sure to find that precedence is given as follows: (1) Smudgy portraits of well-known or unknown persons, preferably brides and bridegrooms. (2) Girls and children doing whatever happens to be seasonable at the moment. They are shown bathing from June to September; on ice or snow from December to February. (3) Football, cricket, golf and other sporting snapshots. (4) Stage subjects and actresses "at home." (5) Comic pictures, and (6) Photographs of real interest, showing important events of the day. There is a marked falling off."

It may be argued that an analysis of the above proves a state of affairs in favour of the amateur and professional worker rather than the legitimate press photographer, and that no harm is done to our profession as a whole, seeing that photographs of one kind or another are used.

Even the most kindly critic, however, will, I think, admit that the art of press photography proper does not hold the important position it once did, which is a pity, seeing that so many operators have worked hard to make themselves proficient in the art of taking subjects the studio worker or the more skilled amateur would not bother about, subjects which were in great demand some years ago, but which to-day are made to give way to subjects of the "still life" and "Kiss Mammy" type.—Yours faithfully.

FOCAL-PLANE.

HELP FOR THE PRESS PHOTOGRAPHER.

To the Editors.

Gentlemen,—It would be a good thing for Press photographers if owners and layers-out of race tracks, playing pitches, etc., and the builders of pavilions, grand stands, etc., gave photography a little thought. It is, I know, a lot to ask of them, but seeing that the camera now plays an important part in the picturing of sporting events, and the publicity we give to them, something, I think, might be done to make our work easier.

I am moved to pen this note by the announcement that a race track with the usual "fittings" is to be constructed at Bournemouth, and that it is hoped to make this town the Ascot of the South Coast. Happily the track is planned in a new manner, and one particularly favourable for photography—if the grand stand is properly placed. The shape of the track is, roughly, a figure of eight—something like that at Auteuil and other Continental courses—which enables one to have a sight of the horses from start to finish of every race. The advantage of this will be appreciated by all who have waited, almost at fever heat and with finger on the shutter release, for the horses to come round the corner—often too suddenly to make a good picture of them.

Then there is the question of the position of the pavilion or grand stand—or, in other words, the lighting on horses or players. All French stands, I believe, have the sun behind them, but the Ascot grand stand faces about due south, and the stands at the July Course at Newmarket have the sun staring them in the face. The pavilion at Lord's has its back to the setting sun, but that at the Oval is not so well placed, and I have yet to see really good cricketing pictures taken from the latter.

There may be some rule for placing a pavilion or grand stand in a certain position, but I do not think such a rule can exist, because of the many different positions I know of; a few are suitable for photographic work, but the majority of them not so.—Yours faithfully,

SPORTS' PHOTOGRAPHER.

TRIMMING AND MOUNTING STEREOGRAMS.

To the Editors.

Gentlemen,—Your correspondent, "C. E. B." (January 27, p. 58), aroused a dormant interest in the writer, a former keen amateur stereoscopic worker.

Regarding the astonishing ignorance as to transposition, I may say that in a set of 200 original stereos I included two purposely untransposed specimens. The experience I had was that every friend pulled up at those two, but their descriptions of the errors always varied in detail, though not in the opinion that *something* was wrong.

Regarding the trimming, the majority of my pictures were trimmed and measured, as "C. E. B." suggests, and dry-mounted with coincident points 2½ in. apart, as mounted. The left picture had more of the view on the right edge, and *vice versa*.

But I took a number of views of small bronze equestrian models, deliberately placing the horse with its outspread forelegs pointing at my lenses. These I mounted with more margin on the left side of the left picture and right side of the right picture—a plain background being employed. Coincident points were 2½ in. apart.

The effect to *all* observers was a startling realism of the animal galloping in front of the mount instead of receding from it, as should most landscape views.

I proved also that by trimming prints exactly coincident the effect on friends varied seemingly according to eyesight. Those with excellent sight could not say whether the picture was behind the mount or in front of it—presumably upholding the theory of trimming, probably unconsciously. Those with manifest defective sight contradicted themselves again and again—a curious phenomenon.

I had a standard stereo camera, and confess I found little use for the rack and pinion separation device of the lenses. These were adjusted at 2½ inches, nor did variation of this distance appear to make any difference in the results.—Yours faithfully,

PHILIP H. WILLIAMS, F.C.A.

The Camera Club, 17, John Street, Adelphi, W.C.2.
February 2

ASSISTANTS' QUALIFICATIONS.

To the Editors.

Gentlemen,—I agree with "Belgravia." Good finishers *are* almost impossible to get. I have had his experience of interviewing dozens of duds, and why? It is largely a question of wages. Finishing, if it is finishing and not simply glorified spotting, takes a woman (or man) of experience, talent and refinemet.

We cannot expect photographers to impart all the necessary knowledge, free, to a paid apprentice, but the assistants should see to it for themselves, go to classes and show a little enthusiasm towards gaining the necessary skill. When gained, however, it should command its price. Fashion artists, illustrators, and other artistic workers are very much better paid than finishers, and this is where the talented girls get to very largely. In one case I know of a firm that nearly had apoplexy at having to pay a really tip-top finisher 50s. a week, when they were paying gladly £3 3s. to a man who helped the outdoor operators and *cleaned the motor car*. That same girl, the finisher, is now getting £5 per week as an operator, and a good finisher is lost to the world. Moreover, that firm is still looking for a really good artist finisher, salary about £2 2s. My good Mr. Photographer you will not find her, for she could not live on it. Standardise wages if you will, and make it worth while for the artist.—Yours truly,

A WOMAN.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A H.—Actual makers of adhesive seals are Messrs. William Sessions, Ltd., The Ebor Press, Earswick Station, York.

W. H. G.—There are not many books on aerial photography. The best general work is "Airplane Photography," by F. E. Ives, published by the J. P. Lippincott Co., and obtainable through any bookseller, price 18s.

A. H. S.—Not practicable to body-dye except in manufacture. You can, of course, stain a gelatine coating, but, for the sake of uniformity of the colour film, it would be better to coat with a dyed gelatine solution. Suitable dyes from Ilford, Ltd., Ilford, London, E.

A. E. H.—(1) Filter Yellow K, or similar dye, from Ilford, Ltd., Ilford, London, E., or British Drug Houses, Ltd. 16-30, Graham Street, City Road, London, N.1. (2) The following metol formula is very suitable. Metol, 150 grs.; sodium sulphite, cryst, 2½ ozs.; sodium carbonate, cryst, 3½ ozs.; potass bromide, 16 grs.; water, 20 ozs.

S. E.—(1) There is no reason why the solution should not keep well. We have kept solution of very similar colour for many months. The solution is just about the same colour as the pre-war commercial solution which kept very well. (2 and 3) We think there is nothing to complain of in the colour. In our experience it is not possible to get a perfectly water white solution. You do not say whether you have tried the developer practically. If it is unsatisfactory in practical use and you will

let us know what is the matter with it we will see if we can help you further.

W. THOMPSON.—(1) Cassell's "Cyclopædia of Photography,' edited by Bernard E. Jones, published at 10s. 6d. It is now out of print, but no doubt you could obtain a copy from Messrs. Foyles, 121-123, Charing Cross Road, London, W.C.2. (2) We could have formed some idea if you had sent a negative. A lens of this focal length ought to cover a postcard plate satisfactorily. With nothing to go upon, we are unable to suggest a cause. (3) Particulars of the focal lengths are not given in the catalogue, but it is quite easy to find the focal length of your lens by focussing upon a distant object, say a church spire half a mile or so away, and then measuring the distance from the lens diaphragm to the focussing screen. At the same time we should think there is very little to gain, in view of the narrow angle of view which is covered, in replacing the R.R. by an anastigmat.

L. H.—The reason for using an anastigmat in preference to a rectilinear or euryscope is that the former has much better covering power at a large aperture, that is to say that the anastigmat would perform as well at *f*/8 as the euryscope at *f*/16, or perhaps even *f*/22. If length of exposure does not matter, the older type of lens will be quite satisfactory. The Thornton-Pickard behind-lens shutter is fitted with loose fronts, so that you can use different sized flanges, or you can have brass adapting rings to fit your smaller lenses and the largest flange you intend to use. You can have these made by Messrs. Taylor, Taylor & Hobson, of Leicester, who stock all standard flanges, or you can get them made to order by Messrs. Fairbrother & Bowen, 9, Farringdon Avenue, London, E.C.4. You must take the risk of the water company charging you for water used for trade purposes. Surely you do not wish to avoid a just claim. At any rate, the extra cost will not be much, especially if you state your intention, and do not leave the water company to find out for themselves.

J. D.—(1) You can obtain actual photographs and coloured postcards from such firms as W. A. Mansell & Co., 405, Oxford Street, London, W.1, but as a collection of these would be rather costly, we should recommend you to obtain some of Gowan's Art Books. These contain in each volume sixty small reproductions of pictures. Each volume is devoted to one artist, and the cost is, we believe, 3d. A more elaborate series on the same lines is "Masterpieces in Colour," a volume containing eight reproductions in colour by one artist, published at about 2s. 6d. If you write to Messrs. Gowan & Grey, London and Glasgow, and Messrs. T. C. & E. C. Jack, London, for lists, you can make your own selection and order through your local bookseller. You can get all particulars of the "statuettes" from Messrs. Campbell Gray, Ltd., 88, Edgware Road, London, W.2, who will mount your own prints in this style at a very reasonable price. (2) Portraits to imitate marble are made by well powdering the sitter's hair and face (a white wig is better than powdered hair) and draping the shoulders with a white fabric. (3) The book, "Trick Photography," is out of print, but you could probably obtain a second-hand copy from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2.

H. C. S.—Steel is not an easy metal to etch by the photo-mechanical method, on account of the difficulty of keeping the resist intact during etching; this, however, can to an extent be remedied by depositing upon the surface to be etched a thin coating of copper. The best dry plate to use for making the negative and positive to print from is either a Wratten Special Process plate or an Ilford Process plate, using the developer recommended by the plate makers, and developing for two minutes at a temperature of 63 deg. F. The plate, after development, must be well washed and then fixed in a fresh hypo bath (20 per cent.) for 10 minutes. A slight reduction to clear away any signs of scum is advisable, using either the cupric ammonium chloride or iodine cyanide reducer, and then to obtain the greatest possible density, intensify with mercuric bromide, and blacken with silver cyanide; this remark especially applies to the positive. Having obtained the photographic stencil, it can be printed on the steel by the bichromate albumen method, and, after development, the ink image be dusted with fine bitumen powder, which must be incorporated in the ink by heating. Should the steel be used without a copper coating, it must, before coating, be well cleaned with the finest pumice powder, then washed and placed in a 10 per cent. ammonia solution; when removed it should be coated at once. The steel is etched in a 35 Beaumé vol. of perchloride of iron, heated to a temperature of 75 deg. F. If great depth is required, it is treated as when etching an ordinary zinc block. The ordinary half-tone enamel can be used for the resist, or bichromated gelatine. This latter resist is obtained by printing upon a special carbon paper made by the Autotype Co., then transferring to the steel, which has been previously ground, as is usual in the photogravure process. The etching is done in a 33 Beaumé bath of perchloride of iron. This method will not give the depth like the first method, but is suitable when gradation is required. Aluminium and brass nameplates can be easily made by the photo-engraving method. Take a piece of highly polished metal and coat with bichromated albumen, print from the negative, and, when printed, roll up with the usual ink, dry, but do not powder with bitumen. Slightly etch in perchloride of iron, and then wash and well dry. Spray or carefully paint over the surface black celluloid varnish; when dry, remove ink image with petrol or turps, which will come away after gentle rubbing with cotton wool. After clearing the ink resist away, the image will show up as polished metal on a black ground. There are many ways of modifying this method to obtain different effects. If you are an engraver, and not acquainted with the working of photo-etching methods, it would be as well to obtain some instruction in the making of blocks. This instruction can be obtained at the L.C.C. School of Photo-Engraving and Lithography, Bolt Court, where the making of nameplates is taught, also facilities afforded to experiment with etching on steel.

M. R. B.—We quite sympathise with you in the trouble you are having. So far as your manipulation is concerned, the only two suggestions which can be usefully made are:—(1) Wash for a very short time (just a rinse) between developing and fixing. It is possible that the production of the stain is concerned in some way with oxidation of the developer before fixing, and, if that is so, you only aggravate the cause by washing for any length of time between these two stages. It's not the most likely of causes, but, at any rate, there may be some result from making the modification. (2) We don't believe in the use of any hypo-killer. We don't know what the hypo-killer is made of—probably persulphate or some similar oxidising agent. But, at any rate, if you wash for half an hour in a constant stream of water which you get in a turbine washer, provided prints are separate and on the move all the time, there is certainly no advantage whatever in using a hypo-killer. We note that you have tried dispensing with the killer, without any benefit. But try leaving out any hypo-eliminator, and also curtailing washing between developing and fixing. Simply give each print a rinse in a vessel provided with a good flow of clean water, and transfer at once to an acid fixing bath, being particular that the print is thoroughly immersed below the surface, say by a "paddle" of wood or ebonite. There is nothing in any other of the particulars which you name to account for the stain, and if the suggestions we have made above are of no benefit, we think you have no alternative but to take the matter up with the makers, getting them to make some prints on marked pieces of the paper.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3224. Vol. LXIX. FRIDAY, FEBRUARY 17, 1922. Price Fourpence.

Contents.

SUMMARY.

The fourteenth Scottish National Salon opened at Hamilton on Saturday last, and remains open until to-morrow week, February 25. Some notes on the exhibition, by Mr. Archibald Cochrane, one of the judges, will be found on page 91.

In a paper compiled for the purposes of a lecture at the Croydon Camera Club, Messrs. Vivian Jobling and E. A. Salt have brought together in a very comprehensible form a consideration of the chief factors determining the speed of a lens. (P. 93.) In the concluding portion of their paper, working drawings and description are to be given of an apparatus for the direct measurement of the F No. of a lens.

M. L. P. Clerc, in his "Paris Notes," announces that it is the intention to celebrate 1924 as the centenary year of photography by holding an international congress and exhibition in Paris. (P. 92.)

At the Royal Photographic Society, on Tuesday evening last, papers by Dr. Svedberg on emulsion grain aroused much discussion. Mr. K. C. D. Hickman, in the course of a paper describing investigation of the washing of plates, demonstrated a very ingenious attachment for use with an ordinary dish, and also a novel eccentric rocker designed on a pneumatic principle. (P. 99.)

The comprehensive paper by the Rev. H. C. Browne on the optical conditions to be observed in the taking, printing, and viewing of stereoscopic photographs is concluded in the present issue. (P. 96.)

The Edinburgh Society of Professional Photographers have recommended a schedule of minimum prices for commercial photographic work. The schedule will be found on page 100.

A feature of the Photographic Fair at the Horticultural Hall, Westminster, May 1 to 6 next, is to be an exhibition of American professional portraiture. (P. 89.)

Photographers in the United States are invited to contribute to this exhibition. A thirty-guinea silver cup will be awarded for the best group of portraits. The judge will be Mr. William Crooke. (P. 101.)

We again draw the attention of assistants answering Box No. advertisements to the imprudence of sending specimens or originals of testimonials to unknown advertisers. (P. 90.)

The print or enlargement giving a bas-relief effect which can be made from a combination of a negative and positive transparency forms an attractive window display. (P. 90.)

In a paragraph on page 90 two prescriptions are given for the reduction of toned over dark P.O.P. prints.

Sufficient pressure of the back in the printing frame or box is a precaution in dealing with double-weight papers. (P. 99.)

EX CATHEDRA.

American Professional Portraiture.

An announcement of great interest to professional photographers is made by Mr. Arthur C. Brookes, organiser of the Photographic Fair, which will be held at the Royal Horticultural Hall, Westminster, from May 1 to 6 next. Mr. Brookes is arranging an exhibition at the Fair of portraiture by professional photographers in the United States. The collection, which is expected to number several hundred, will be arranged in the lecture hall, which on previous occasions has been used for the meetings of the P.P.A. Congress. American professionals have deservedly a reputation for originality and variety of style, and there can be little doubt that an exhibition of more than ordinary interest will be brought together. Mr. Pirie Macdonald, when addressing the professional photographers gathering in London last summer, dwelt particularly upon the versatility of his compatriots, and instanced quite a number of men in different parts of the United States whose work ranked as regards freshness and outlook with any which he had seen in Europe. The exhibition will be open to all visitors to the Fair, and, if recent public and private correspondence which has reached us is any criterion, the Fair itself will be attended as largely as hitherto by professional portrait photographers in London and the Provinces. Portraitists should, therefore, make a note of this opportunity of seeing a representative collection of American work, for it should prove to be a much larger and more important one than has previously been brought together.

* * *

Printing Double Weight Papers.

The continuously greater use which is being made of double-weight papers of practically postcard substance for portrait photographs, inserted without mounting in the popular folders, calls for somewhat greater care in printing. The curl of a fair-sized piece of such paper may easily be such that proper contact over all parts of the negative is not obtained in a printing frame fitted with the customary rather weak springs, or in a printing box if hand application of the pressure back chances to be done in a careless manner. With some printing boxes uniform pressure of the back calls for correct manipulation of the handle, and when a thick paper is being used, it is quite possible to have faulty contact over part of the negative. In many cases this liability may be readily remedied by thickening the pressure pad by fixing a stout piece of felt to it, or by laying a piece of felt upon the paper after inserting a fresh piece of the latter. A precaution such as this will, of course, be taken by the experienced printer, especially if he has been accustomed to handle carbon tissue, the pronounced curl of which calls for the frames of extra solid construction provided with strong springs fitted to hinged cross bars. The fact that exposure of papers is often placed in the hands of

comparatively unskilled assistants is no doubt responsible for defects of definition in prints which have been submitted to us with the suggestion that the lens was at fault. That such was not the case should have been evident from the fact that the unsharpness occurred in different parts of the subject from the same negative.

* * *

Assistants' Specimens. Our publishers ask us to remind assistants that it is unwise to send specimens of their work to advertisers whose announcements appear under a box number. It is evident from many of the packages which are addressed to our publishers for transmission to box-number advertisers that this caution is being disregarded by many. In their own interests we hope that assistants will bear it in mind. It is quite unnecessary that they should send specimens in the first instance, because we expressly prohibit the request for specimens in an advertisement which is issued under a box number. There was in the past much abuse of assistants in this way, and our prohibition has been made for the purpose of protecting assistants from unscrupulous people who endeavoured to make our advertisement pages the medium for obtaining specimen photographs. Assistants, we are sure, will understand that they are only nullifying this protection by sending specimens of their work to people of whose identity they are ignorant. Although not in quite the same category, this caution applies also to originals of testimonials.

* * *

Reducing P.O.P. Prints. While an over-developed bromide or gaslight print may be reduced in depth with so little alteration of its colour as to allow it to pass muster among others which have been correctly developed, there is unfortunately no reducer which will render a similar service to a P.O.P. print which is darker than others of a batch. Nevertheless, occasions arise when it is convenient to be able to correct the error of over-printing in the case of a single print, for example, when a P.O.P. is required at very short notice and time cannot be spared to take off another from the negative. In these circumstances there are two reducers which in our experience answer admirably for the purpose. One is the ordinary persulphate reducer, which certainly alters the colour of the print, but in a manner rather favourable than otherwise, changing the purplish image to one more in the direction of a cold black. The other reducer is that made by dissolving about 10 grs. of potassium ferricyanide and 20 grs. ammonium sulphocyanide in 4 or 5 ozs. of water. Both of these formulæ work without any liability to stain and exert their reducing action on a print which has been toned in the ordinary gold bath.

* * *

Bas-Relief Portraits. A form of photograph which, from its peculiar character, attracts the attention of the public and, therefore, is of service for occasional window display, is one which imitates in a more or less realistic way the effect of bas-relief. It is very readily made from almost any portrait negative, although really effective results are obtained only from subjects in light tones, such as feminine head and shoulder studies, and particularly those into which lace or other fabric of pronounced texture enters. From the negative a positive transparency is made by contact on celluloid film. The commercial variety of the Eastman portrait film serves very well for this purpose. In the exposure and development of the positive the aim should be to secure density corresponding as closely as possible with that of the negative. After fixing, washing and drying the positive is bound, film to film and slightly out of register, with the negative. The two together then serve as a "negative" either for contact prints or enlargements. Some very attractive results are obtainable by this process, given a suitable original. An example of the method was shown at the last exhibition of the London Salon by Mr. Marcus Adams. There may be a few people, say among the theatrical profession, who will purchase photographs in this style, but, generally speaking, a photographer may reasonably regard the process as one which every now and again may be used to provide a print for the showcase which will attract the passer-by.

QUIET TIMES.

The two months which follow Christmas are generally acknowledged to be the quietest as regards business in the photographer's year, and at the present time this dullness of business is perhaps more noticeable than it has been in any previous year, as we hear of reductions in staff and closing of branches by some of the larger concerns, while there is a general complaint of lack of orders in smaller ones. Many causes contribute to this state of things, which is, of course, due to the general disorganisation of the trade of the country. It would take too long to trace the connection in detail, but the fact remains that portraiture is a luxury trade, and consequently suffers before those branches of commerce which deal with necessities, while commercial photography is more or less dependent upon activity in other trades, and must needs experience the same depression as they do. This reads rather like the talk of Job's comforters, but it is none the less true, and while it is a poor consolation to be told that it is no worse for photographers than for other traders or manufacturers, it is something to be assured that it is no decline of interest in photography that is responsible for our troubles, but simply inability on the part of the public to buy photographs. In one respect the photographer has great cause for thankfulness; he has no heavy stocks to be affected by fluctuations in the market, and he has not such catastrophes to face as the loss of eight millions by a great rubber business from this one cause, or the turning of a yearly profit of over four hundred thousand pounds into a deficit of nearly the same amount on trading in the course of a single year, as recently experienced by a great drapery firm.

It seems therefore that there is no reason to be unduly pessimistic over the future of photography as a business. It is taking its share of the general troubles, and this is less disquieting than a serious slump would be in a time of all-round prosperity. It is to be hoped that in the commerce of the nation this is the darkest hour which comes before the dawn of renewed prosperity; a dawn of which with the eye of faith we already have a glimpse.

The campaign for economy which is now in full swing should have positive results, provided the public does not slacken its demand for reduction of State expenditure. Within a reasonable time, large sums which are now being spent upon unproductive work should remain in the hands of those who have earned them, instead of being taken out of their control in the form of taxes. When it is considered that at least one-third of the total income of the leisured classes is now being absorbed by income tax alone, it is small wonder that these classes, formerly the photographer's best patrons, are not giving orders on the scale of former times. At the other end of the social scale unemployment is rife, and many working classes families have one or more idle members to be kept out of wages which are not too liberal or regular.

The situation should not, however, be faced by merely acknowledging the existing conditions and quietly waiting for things to mend. The less money there is to be spent the greater must be the energy displayed in getting a fair share of it. The most energetic and progressive of our great retail firms recognise this to the fullest extent, and are advertising on a more lavish scale than ever before. The lesson they teach should not be missed by the photographer, who must explore every avenue through which business may possibly come to him. His display should be as fresh and attractive as he can make it, and his old patrons constantly reminded of his existence by letters or circulars announcing his latest introductions, special styles being devised to form an excuse for the communication. The commercial photographer may carry out this idea in a more generous way, as not only may he circularise firms in any line of business who can use photographs, but he can advertise in the various technical journals, particularly those connected with the building and engineering trades. In nearly every other business a large proportion of orders is obtained by direct personal solicitation or "travelling," but we seldom hear of this in photography, except in connection with "shop front" and school work. There is an old saying among business men that a man who spends less upon his advertising than upon his rent is dead to his own interests, but modern experience teaches that the outlay upon advertising should be in a much higher proportion, and it should be carried on persistently and regularly. A small effective announcement which appears regularly will yield a better return than a larger one which appears once or at long intervals. As regards the cost, this may, to a certain extent, be met by delaying the purchase of new apparatus or furniture, which can be procured as soon as the advertising, in whatever form it may take, has done its work. One caution is necessary; it is, not to be discouraged by the non-arrival of orders immediately after an advertising effort; an advertisement is often working months, even years, after its publication. Also, if a good return is apparent from advertising, keep on; do not think that the boom will be permanent. Do not expect too great a return upon the money expended. If orders which can be reasonably attributed to an advertisement pay for it and yield a net profit equal to the amount spent upon it, it is worth going on with, as the indirect influence which is greater has cost less than nothing. "Sweet are the uses of adversity." May the present depression prove a blessing in disguise to those who in the past have waited for business to come to them, but who are now driven to strike out to keep afloat.

THE SCOTTISH NATIONAL PHOTOGRAPHIC SALON.

The exhibition of the Scottish Photographic Salon is held this year at Hamilton, an historic town in the heart of a populous district. The clansmen forming this federation have gone forth in their strength and raided the beautiful glens of their native country and scoured the moors, bringing back much rich booty. The best of the "bags" resulting from these expeditions are shown at this annual Salon. Some 270 pictures have been selected out of 700 submitted. The board of selectors were Archibald Cochrane, Robt. Chalmers, F.R.P.S., and J. Campbell Harper.

The general standard of the exhibition is well maintained, and rivals that of any previous collection brought together by the Federation. The predominating printing process is bromide. In certain instances prints suffer from technical defects due to development troubles, but from those workers who have got a developer to suit the bromide paper they specialise in some beautiful prints result, with often as fine a black as could be desired. The few examples of Bromoil do not show that any particular pictorial quality has been secured by the addition of the oil pigment except in atmospheric renderings.

An outstanding exhibit of fifteen prints of a high quality are sent by Dan Dunlop. If these do not show any further ripening of this artist's powers, his high standard of pictorial output is at least maintained. Hector Murchison submits three pictures, the best being, to my thinking, of "Blakeney Mill" (115). This is a masterly portrayal of a fine subject, the fine atmospheric effect being most striking.

Taking the exhibits in the catalogued order, we remark No. 1 by the secretary, Jas. F. Smellie, a fine print of "Drumadoon Point," of most pleasing quality. "Morning Mist" (6), by Wm. Fraser, whilst a little weak in foreground, has fine quality and very pleasing atmospheric effect. "York Minster" (12), by Thos. Carlyle, shows a rich, strong print marred somewhat by flatness of bars of light on the pillars. "Spring" (13), a Bromoil by Wm. Simpson, has charming atmospheric effect. I think the oil pigment was a helpful contributory in this instance. "A Dream of the Raphoh" (22), by J. M. Whitehead, has this worker's high technical quality; the hard lines of the silhouetted hill are a little harmful to the pictorial effect. "Buist" (25), by J. Lohoar, is a delightful little print, the atmospheric effect being quite charming. The oil pigment has again been helpful. Shall we say, then, Bromoil for aerial perspective and atmospheric effects when foreground is free of ropes and masts? This seems to be the most convincing of the uses of oil pigment additions.

Another very fine picture (29), by J. M. Whitehead, is a print of very rich quality. No. 49, by Mr. McLennan, is in coloured bromoil. The bulk of the coloured work submitted was not acceptable, as prints were in most instances pastel drawings. The coloured Bromoil alluded to above is quite legitimate in method of production; very slight colour has been added to a rich deep brown print, but the gain in artistic value is very slight, if any. "Craigmillar" (57), by Geo. Raeper, is a rich Bromoil print, in which the castle is well presented. "Happy Days" (60), by Linton Gibb, is a very charming little picture, reproduced as frontispiece in the catalogue. In "Joyous Summer" (71), by J. M. Whitehead, I like the higher key which has been struck. This is a fine picture, but I do not much care for the cold bluey colour of his print. The purer blacks of the reproduction in catalogue help to show what this work would gain with a purer colour effect. "The Crooked Chimney" (97), by Chas. A. Allen, is well handled, but the architectural lines are not quite pleasing. "The Cloud" (100), by Dan Dunlop, is a most successful essay, the atmospheric effect being its most successful feature, achieved without the use of Bromoil. "The Muddy Road" (103), by Jas. Lindsay, is a fine quality print. The left hand light reflection is a bit disturbing, and should be further "sunned" down.

"The Great Splendour" (109), by J. Baird, is a most successful essay in recording distance in landscape. I should prefer the retreating distances a little darker, particularly the most distant hills. "A Bridge on the Teith" (114), by W. W. Weir, is a most successful picture, and very originally treated. The big window on the picturesque old bridge is too solid in character and wants breaking up with some scattered lights. "Reflections" (116), by W. R. Fernley, is skilfully handled, flesh tones being particularly well rendered in pr[illegible] light key. "The Leny in Spate" (120),

by John Baird, gives a fine sensation of the rushing waters; it is a print of a fine rich black in bromide. "The Goods Entrance" (123), by A. T. Edgeley, is a clever composition; the nearest figure should be in sharper focus. No. 128, by Chas. Allen, a good subject, suffers from a monotony in the treatment of high-lights of the picture. In No. 131 we see Mr. Dunlop quite successful in seascape, but in No. 162 I do not think he is so successful. Of the riches of light and shade some should have been left out; the composition is "Too Busy." In No. 167 the foreground of seascape is a little gaunt and hard, but in a way this has its use in emphasising the beauty of the distance. To finish with Mr. Dunlop's contributions, I regard "The Palace Courtyard, Stirling Castle" (175), as an excellent piece of work; it has only one defect; this will be discovered if carefully sought by the analytical patrons of the show.

"A Quaint Corner," Culross" (208), is a fine quality print; the composition is odd, but quite pleasing. No. 210, by Mr. Cairns, is a child study happily caught. A "Wilkie-like" subject, "When the Cat's Away" (234), has been very cleverly carried out. "Interested" (236), by John Smith, I consider a most happy performance of decorative design. No. 238 is an excellent portrait of C. Pollard Crowther, Esq., by Mr. Brinkley. No. 243, a sea and sky composition by Miss K. M. Alexander, gives fine rendering on a long scale of delicate tones, a scheme in which photography excels. "Cintra Palace" (244), by A. M. Clark, is a picturesque presentation of pleasing architectural work, most capably carried out. "The Fish Cleaners" (248), by Chas. A. Allan, is a good subject handled in a masterly way.

Robert Chalmers, of Sunderland (his birth certificate is right) shows half-a-dozen prints of his latest and best work. Whilst having a great appreciation of "Youth" (171), I think that the composition suffers from a too central division of the light and shade. "Hilda" (164), by this same worker, is a portrait of a sweet girl, and has a pleasing range of tones. "Framivillgate" (193), is altogether a most satisfying little picture. "Pensive" (197), is in a line Mr. Chalmers has made his own; a very simple and effective portrait.

There is a collection of beautiful work by Marcus Adams, F.R.P.S., sent in response to invitation. Many of the prints are already well known from reproduction in photogravure. I am of opinion that this process of reproduction was responsible for the "too white" high-lights, but I find here in Mr. Adams' work a tendency to use the white paper base in rendering of his many high-lights. No. 280, is a beautiful girl portrait, but suffers slightly from the over-dark rendering of left-hand. No. 279 suffers from a plethora of high-keys. left hand. No. 279 suffers from a plethora of high-keys No. 294 is a charming picture, but the high-lights almost too pure. No. 304, a beautiful boy portrait, in the right key, except for one too white note in collar. These prints sent by Mr. Adams are a great acquisition to the exhibition, and this fine contribution will be much appreciated.

There is a collection in the second hall of Canadian work, and I have been interested to see what kind of pictures our overseas photographic brethren produce, but I am a little disappointed after seeing what their U.S. neighbours have been showing us. Of the work on the wall, No. 301 is a good portrait with some beautiful tone values, but the composition is the worse for the straight white line of arm. No. 324, "A Moment for Thought," appears to be a "gum" print fairly well done. No. 328 is nearly a success, but too broken in the rendering of high-light detail. No. 337, by Mr. Moore, is cleverly done, and has subtle tones happily rendered. No. 348, by Mr. Soulsby, is a pleasing little portrait.

ARCHIBALD COCHRANE.

PARIS NOTES.

The Centenary of Photography.

THE first photographs deserving the name, that is to say, the first images of outdoor scenes obtained by means of a camera fitted with a lens, and of a degree of permanency such that subsequent action of light did not affect them, are certainly the images on metal, glass and paper rendered sensitive with bitumen of Judæ which were obtained by J. Nicéphore Niépce in the years 1822-1824, subsequent to Niépce's earlier experiments in the reproduction of engravings. Following the suggestion made some months ago by the "Revue Française de Photographie," the French Photographic Society, in conjunction with various professional associations, has formed a committee for the commemoration of the centenary of this discovery, and has fixed the year 1924 as the most appropriate time for the celebration. Provided that the plans which are now being made come to a successful issue, an international congress of photography and an international exhibition representing the historical, artistic, scientific, industrial and commercial branches of photography will be held in Paris. The French Academy of Sciences and the Académie des Beaux Arts have already signified their patronage of this programme, and other official support may be counted upon. The difficulty which faces the promoters is that of finding a suitable place providing the accommodation which such an exhibition requires. As soon as the necessary plans have been made, particulars will be forthcoming as regards the congress. The full reports issued of the last international congress held in Brussels in 1910, and published almost in their entirety in the "British Journal," are sufficient to show the importance of a gathering of this kind. A subsequent congress, which was to have been held in London in 1915, in conjunction with the Royal Photographic Society, was in process of organisation when the events of July, 1914, decided otherwise. The French organising committee has still a lively recollection of the aid then offered in Great Britain, and hopes to receive a like support when the plans for the centenary congress are further advanced.

Tests of Process Lenses.

At one of the recent meetings of the photo-mechanical section of the French Photographic Society, M. Démichel, a Parisian photo-engraver, described a very simple method of testing lenses to be used in process work. On the copyboard is arranged a test chart formed by placing side by side a number of prints from the same half-tone block, made with a screen of 150 lines per inch, and the camera extension is set for a reproduction to half scale. Care requires to be taken that the plane of the copyboard and that of the sensitive plate are exactly perpendicular to the optical axis. Any error in this respect is, however, shown by unequal distribution of definition in the image. The average size of the elements of the half-tone original are 1-300th of an inch, and therefore the average size of those of the reduced reproduction is 1-600th of an inch. Any lack of sharpness of the image, even when it is of the order of 1-2500th of an inch (1-100th of a millimetre), sufficiently affects the proportion of the black and white elements forming the screen image to modify in a very marked manner the gradation of the copy, this gradation depending precisely on the proportion of the black (or white) per unit of surface.

M. Démichel has compared in this way an apochromatic Tessar and a Cooke process objective, each of about 25 inches

focal length. Whilst at f/15 the Tessar covered well a 24 × 20 plate, the extreme corners, however, showing traces of astigmatism, nothing is gained as regards sharpness or effective covering power by stopping down. On the other hand, with the Cooke process lens the plate which is sharply covered with a relatively large stop is a little smaller, but a considerably larger plate than 24 × 20 is covered by stopping down.

These data are plainly of value only in respect to the two lenses which were under comparison, but they show the usefulness of this simple method, which can be employed for determining the stop to be used according to the size of plate requiring to be covered when employing any one of the lenses in a process establishment.

It should be added, to avoid misunderstanding, that a test of this kind is not applicable to a lens which is to be used for the photography of relatively distant objects, *e.g.*, landscapes or architecture. A lens, as the result of its corrections having been carried out specially for use on a copying camera, may be perfect for this purpose, but distinctly imperfect for the photography of outdoor subjects; and *vice versa* the corrections of a first-rate lens for outdoor use may prove insufficient for copying work.

A Density Tester for Cinematograph Film Negatives.

In a previous instalment of these notes I referred to the printer of cinematograph films designed by M. L. Lobel, in which automatic adjustment of the strength of the light is made by the passage of the negative film through the apparatus. M. Lobel has now designed a very ingenious apparatus by which the printing value of a film negative may be rated. He calls it the "Etalonneuse Filmograph." In the ordinary way a film negative is rated by eye judgment, with the aid of one or two standard negatives, a method which requires an extremely skilful operator, and even then is liable to error. An alternative method is to test the film negative by printing from it on a few test lengths of positive film under different conditions; then, after development, judging the exposure which should be given. Apart from the considerable quantity of positive film required for this process, the method takes time; and, moreover, is least efficient in these two respects under the conditions most generally prevailing in the making of cinema films, namely, the assembling of many short lengths of negative.

By means of M. Lobel's "Etalonneuse" a series of eight successive exposures are made from a single negative of the film band by successive addition of seven increasing resistances to the electric circuit. The apparatus then comes to a stop, and the negative film can then be unrolled by hand up to the point at which a notch marks the place for alteration in the strength of the light. The machine then starts again, and exposes a new series of eight from the negative presented to it. Thus it is easy, after development of the test positive film, to choose for each section of the negative the conditions of exposure which will give not simply a satisfactory positive, but the best positive which can be obtained from the negative.

A Museum of Cinematography.

M. J. Demaria, president of the Chambre Syndicale Française de la Cinématographie, has recently taken the initiative towards the establishment of a museum of cinematography. Although the industry is scarcely more than 25 years of age, it is one of those in which progress has been most rapid, and a useful purpose would certainly be served, unless it is already too late, by collecting examples of apparatus of all kinds which have been successively employed, abandoned, or, as probably has been the fate of most, sold as scrap metal. The specimens collected for the museum are to be for the present in the charge of the French Photographic Society until their ultimate place of preservation has been decided.

Automatic Timing of Printing Machines.

Clockwork mechanism for the automatic control of the time of exposure in photographic printing appliances has been frequently employed in the past as a means of setting a printer to give an exposure of so many seconds or minutes. The mechanism has been more or less similar to that employed for the lighting of the stairways of flats in Continental cities, by which the dweller, by operating a switch, is given a limited number of seconds to make his way up the staircase to the first landing, there operating a second switch if his flat is higher up. But these clockwork devices are usually somewhat fragile, and will not stand the hard wear to which they are subjected in a photographic printing room. MM. Godefroy Frères have recently introduced a very strong automatic "timer" for printing machines, constructed without any clockwork mechanism, but very easily adjustable over a wide range of exposure times, any one of which can be repeated with great accuracy.

L. P. Clerc.

SOME FACTORS CONCERNING THE RAPIDITY OF A LENS.

[The following is the text of a paper read at a recent meeting of the Croydon Camera Club, where it was accompanied by a demonstration of the apparatus for the direct measurement of the F No. of a lens which Mr. Jobling has designed as an improvement on that of C. Wellborne Piper described in "B.J.," 1917, p. 272. Messrs. Jobling and Salt contrive to convey the facts, and even certain of the more recondite considerations in lens rapidity in a form which involves small sacrifice of exactness for the sake of the elimination of the tabooed mathematical symbols.]

This paper was originally intended and partly written by one of us for an informal summer meeting, since when the subject has been dealt with in a very comprehensive manner by Mr. Geo. E. Brown in the pages of the "British Journal of Photography." A mass of very useful data for the serious student has been brought together by him, some of it perhaps of rather formidable aspect to the average reader. It is to be hoped that the articles, with any additions that may suggest themselves, will ultimately be presented in book form.

The scope of this paper is much more modest, and is intended to appeal mainly to beginners in photography and to others who have never troubled themselves about the simplest problems in optics. Often we find that the men who do the best work know little or nothing about optics, whilst others crammed full of lore do not come up to expectations in practical achievement. Most certainly it is not necessary to be an expert in optics and chemistry to be a first-class photographer, and equally certain is it that a rubbing acquaintanceship with underlying principles need not rob the technician of his technique, or the pictorialist of his inspiration, but should usefully supplement both.

All that will therefore be attempted is to touch upon, in the simplest possible language, the irreducible minimum of what a photographer should know concerning the somewhat dry subject selected, adding thereto some relevant matters of more general interest. The many familiar with the ground traversed

will remember the time when it was unknown and be reconciled to boredom.

Some who practised hand-camera work, before the introduction of the rapid anastigmat, may well be perplexed at the insistent demand by amateurs ever for greater speed in lens and plate. In old days few, if any, lenses of normal focus would cover a plate sharply at a larger aperture than *f*/11, which for that reason was a favourite stop, and the luxury of a rising front was almost out of the question. Nevertheless, with lenses and plates of far lower speed than those of the present day, much first-rate work, even under difficult conditions, was accomplished. Generally speaking the hand-camera then was a heavy and bulky thing, which permitted slow shutter speeds in the hand without risk of movement during exposure.

Excluding the reflex camera, now-a-days weight and bulk have been cut down to such a point as to greatly increase liability of shake during exposure, and in consequence subjects containing nothing in motion often receive what would be considered a top-speed instantaneous exposure in the past. Apart from Press work and sporting events, comparatively few subjects require a shorter exposure than 1/20th or 1/30th of a second, and it should never be overlooked that halving a shutter speed is equivalent to doubling the working speed of the lens, with the added advantage of greater depth of field.

The rapidity of a lens, omitting some qualifying factors, depends upon two main things, one being the amount of the light passed by the stop, the other being the scale of the image —or in other words the size of individual objects depicted, which is dependent upon the focal length of the lens, and must not be confused with the amount of view included on the plate.

As is well known, the area of a circle bears a definite relationship to its diameter. Double its diameter and the area of a circular stop or diaphragm is increased four times, transmitting quadruple the light. Conversely, halve its diameter and the area is decreased four times, and one-quarter the light only passes. Therefore, if any lens is fitted with four stops whose openings have diameters of 1, ½, ¼, and ⅛ inch respectively, exposures will be in ratio 1, 4, 16, 32, or inversely as the square of the diameter of the stop. That is to say, if one second be right for the largest stop, 32 seconds exposure is demanded for the smallest. In practice such a series would present inconveniently abrupt steps.

Beginners occasionally fog themselves by overlooking that ratios are only dealt with in stop nomenclature, and that the proportion that the light passed by one stop bears to the light passed by another, is invariably determined by their respective diameters. In photographic practice it is not necessary to know the actual area in square inches of any stop.

The scale of the image, as has been said, is dependent upon the focal length, or "equivalent focus" of the lens, which is the invariable distance between the focussing screen when a sharp image is formed there of a distant object, and a certain point located inside or outside the lens. This is termed the "principal point" or "node of emission" (in old text books often designated the "optical centre") and its position varies in different lenses.

The scale of the image in conjunction with focal length conveniently forms a starting point to an understanding of the usual method of indicating the relative rapidity of different lenses. Suppose we have two lenses, one of 8 inches and the other of 16 inches focus, both fitted with a stop or diaphragm opening of 1 inch in diameter, which obviously will pass the same amount of light, and with each lens in turn a fairly distant square building is focussed. If with the 8-inch lens the image of the building is reduced in scale to 1 square inch, then with the 16-inch lens the building will be rendered 2 inches square with an area of 4 square inches.

Doubling the focal length therefore gives an image twice linear. The light passed by the stop in this case being distributed over four times the area, at any given point has only one-fourth the intensity of that afforded by the 8-inch lens. To obtain equal rapidity a stop is therefore conditioned that will pass four times more light, which, as we have just seen, is fulfilled by one of twice the diameter or 2 inches across.

The next point to note in the example given is that for equal rapidity the diameter of the stop in each case is one-eighth the focal length. What is true in these two cases is true in all, so that no matter how the focal lengths of lenses may vary, stops having diameters one-eighth of their respective foci will be of the same rapidity, or, in other words, will transmit to the picture plane images of the same light-intensity (or for present purposes must be considered to do so). This being recognised, it will be equally apparent that stops representing any other common fraction of the focal length, such as one-sixteenth, will also give exposures identical with each other.

In the now almost universal method of marking the relative values of different stops, known as the "*f* system," a series of diameters of certain fractions of the focal length is taken, so calculated that each stop is just half the *area* of the larger one immediately preceding it, and thus requires double the exposure.

Naturally, some definite fraction of the focal length must furnish a starting point either for an ascending or descending scale, and in this country one-fourth the focal length has been adopted, usually expressed shortly as "*f*/4." The descending scale is represented by *f*/5.66, *f*/8, *f*/11.3, and other fractions familiar to all as engraved on lens mounts.

To obtain this convenient sequence the diameters of the stops are made proportional to the square roots of the times of relative exposures, namely, 1, 2, 4, 8, and so on in the same progression. But for most practical purposes all we need to remember is that 1.414 (1.4 near enough) is the square-root of 2, for then we can check diaphragm markings, or find the standard *f* values of continental lenses marked differently, sometimes merely with the actual diameters in millimetres of the diaphragms.

Or we can make a set of waterhouse stops to replace ones missing, which is often the case with old lenses picked up second-hand.

To take the simplest case, that of a lens whose largest stop is in the regular sequence and whose *f* value is known—an *f*/8 R.R., for example. Accepting the full opening as correct, and it will probably not be far out, we need not bother about the focal length. We carefully measure the full opening and divide it by 1.414, which will give us the diameter representing *f*/11.3. Half the diameter of *f*/8 will be *f*/16, and half of *f*/11.3 will be *f*/22.6, and so on.

Starting with any other stop in the regular sequence, the same procedure, of course, applies. Thus, dividing the diameter representing *f*/4 by 1.414 gives *f*/5.66, and halving the former gives *f*/8. Quite a simple procedure, and not infrequently of real utility, yet how few, if any, text books written for the less advanced worker condescend to any such plain statement. Parenthetically, it may be remarked that one standard text book written on popular lines describes the *f* system in such terms of incomprehensibility to the unmathematical mind as to amount to positive genius in the traditional scholastic line.

With near objects, which require a greater camera extension than with distant, it will be apparent that the lens for the time being is working at a longer focus and the nominal value of the diaphragm opening is reduced. Particularly is this the case in portraiture and enlarging, and formulæ for dealing with such cases are abundant. Personally, we have never met a photographer who bothered his head one jot about the working *f* value of the lens under these conditions. In portraiture it would hardly be politic to ask a sitter to maintain a pleasant expression whilst the necessary calculations were being made. Estimated exposure based on experience suffices, a more generous allowance being made for large heads than full-length figures. When reducing or enlarging, a table,

ch as the useful one compiled many years ago by the ean Mr. W. E. Debenham, is usually consulted, and saves world of trouble.

In the majority of cases the largest apertures of modern nastigmats do not fall within the standard series. The lative value of any two stops is simply arrived at by squaring th the *f* numbers and dividing the smaller number by the ger, when the quotient gives the relative speed of the larger p with the smaller as unity. Thus, comparing *f*/8 with 3. *f*/8²=8×8=64. *f*/6²=6×6=36. 36÷64=.56. Expo- es will be in ratio 1 to .56.

Prior to the introduction of the anastigmats, the then iversally employed and still largely used rapid rectilinear s has caused its usual maximum aperture of *f*/8 to become mental standard, and most of us estimate the greater speed the newer lenses as in relation thereto. Taking *f*/8 as ity, a table has been prepared which gives nearly all the l apertures of anastigmats on the market.

In the first column the *f* numbers are given; in the second e relative exposures; and in the third the relative rapidities.

aphragm *f* ratio	8	7·7	7	6·8	6·5	6·3	6·2	6	5·8	5·6	5·5	5	4·8	4·5	4·3	4	3·5	3
lative exposure	1	·92	·77	·72	·66	·62	·6	·56	·53	·5	·47	·39	·36	·31	·29	·25	·2	·14
lative rapidity	1	1·1	1·3	1·4	1·5	1·6	1·7	1·8	1·9	2	2·1	2·6	2·8	3·1	3·5	4	5·3	7·1

t will be observed that the aperture *f*/7·7, which looks perior on paper to *f*/8, is practically of the same rapidity. e popular aperture of *f*/6.8 requires about three-quarters exposure, not a very appreciable reduction; the new rmal standard aperture of *f*/6.5 requires less than a third; 6.3 about one-fifth; and *f*/6 one-seventh.

In the case of a landscape lens with the stop in front, as ordinarily used, its actual diameter represents the true *f* ue, whatever its distance. An increase of distance merely stricts the covering power, and, other things being equal, oduces more distortion of straight lines falling towards margins of the field.

Though negative lenses are employed in their construction, lens designed for taking photographs are positive com- nations, an ordinary magnifying glass being a powerful itive lens with aberrations uncorrected, and most of us one time or another have focussed the image of the sun paper for the purpose of igniting it. Here the light from distant luminary falling on the lens in passage through begins to come down until it comes to a focus where it compressed into such a small area as to result in intense t.

In the same way light falling on the front surface of a tographic lens after emergence is cone down or com- ssed, and will pass without loss through a circular aperture of less diameter than that of the front illuminated surface. Consequently, if the stop is of lesser diameter than the lens in front of it, which is almost invariably the case, the effective aperture and *f* value are always greater than a mere measurement of its actual diameter would indicate.

The rapidity of a landscape lens will therefore vary according as the diaphragm is in front of or behind the lens, which is one of a type known as of "inconstant aperture." A practical illustration of this was given by Dr. Zschokke in the "B. J." some years ago in connection with a Goerz "Dagor" double anastigmat, whose two components are of identical focal length.

With the front component used alone in its normal position in advance of the diaphragm, all the image-forming light falling on the front surface of the lens is transmitted through the diaphragm opening of lesser area owing to the coning down of the light, and the effective aperture is *f*/11.8. With the back component used behind the diaphragm, the effective aperture is restricted by, and coincides with, its actual area, and is reduced to *f*/13.6. The brightness of the image in the first case is therefore nearly one and a-half times greater than in the second.

In doublet and other lenses built up of more separated lenses, this coning down of the light may be appreciable or negligible. The well-known Aldis *f*/6 doublet is an example of the former, the actual diameter of the diaphragm being considerably less than the diameter of the incident bundle of light on the front lens' surface—in ratio .87 to 1.00. It is also a good example of a doublet of inconstant aperture, the full aperture of *f*/6 being reduced to *f*/6.9 when the lens is reversed. Inconstancy of aperture may operate as a disturbing factor when copying and enlarging, but otherwise is of little account.

The amount of the coning of the incident light by the front lens is, of course, a measure of its magnifying power, and the magnified image of the diaphragm as seen through the front lens by the eye is the effective aperture. Consequently, if the focal length of the entire lens be known, the effective aperture of the full opening can be ascertained by measuring the diameter of the magnified image. In the same way can be found the actual diameter representing the effective aperture of the largest standard stop, the smaller stops in the regular sequence being determined in manner already described.

VIVIAN JOBBINS,
E. A. SALT.

(To be continued.)

INDUSTRIAL FAIR AT BARCELONA.—The third International Industrial Fair of Spain will be held from March 15 to 25 next at Barcelona. Particulars are obtainable from the Spanish Travel Bureau, 11, Queen Victoria Street, London, E.C.4. A series of special tours is being arranged for the convenience of those wishing to visit other Spanish towns in conjunction with spending several days at Barcelona.

PHOTOGRAPHING SALUTING CELEBRITIES.—In taking up a position from which to photograph a Royal or other procession, the lighting is, of course, the first consideration (writes a correspondent), but there is another important factor to be taken into consideration when in such procession there happens to be a male whose duty or custom it is to acknowledge the salutes of the onlookers, namely, the possibility of the raised hand, arm, or even a hat hiding the face. A number of Press pictures taken of the Prince of Wales in India have been quite spoilt because the exposures were made at the moment when the raised arm, hand, or hat covered the face, and the unfortunate defect is quite common in pictures of other celebrities in this country and elsewhere. Salutes can, of course, never be timed to suit exposures, or exposures to suit the salutes, and in all cases one has to trust to luck—luck which is too often against the operator. Some operators make a point, when possible, of getting to the "still arm" side of the subject when continual saluting is expected, and this appears to be the only remedy. An operator on the saluting-arm side runs a big risk of failure.

B

THE PRACTICAL STEREO PHOTOGRAPHY OF SMALL OBJECTS.

(*Concluded from page* 80.)

The practical outcome of this for the ordinary worker is that when high magnifications are attempted the smallest available stop should be used, and that the near face of the object should be placed exactly in the plane of the verticals on which he has previously focussed sharply with full aperture. Magnifications up to 20 or 25 diameters, which can be secured with a lens of 0.5 in. focus, would be extremely useful in the photography of thin transparent sections of minerals, but great skill will be required to secure the best result—the skill necessary in all microscopic work.

The following comprehensive table, covering a very wide field, sets out in easily available form the results of our inquiry as adapted for use with the suggested 4-in. stereoscope. Its use will be made clear by examples.

TABLE I.

For use with standard stereoscope only. Dimensions in inches.

Image distance ..	12	16	20	24	28	36	40	56	72
Image width ..	7.5	10	12.5	15	17.5	22.5	25	35	45
Print width ..	1.88	2	2.08	2.14	2.2	2.25	2.27	2.33	2.37
Eye separation ..	2.25	2.33	2.38	2.41	2.44	2.47	2.48	2.52	2.53

Magnification									
1..	2.5	3	3	(3)	3	3.5	3.5	(3.5)	3.5
2..	(2)	2.5	(2.5)	3	3	3	3		
3..	2	(2)	2.5	2.5	2.5	3	3		
4..	(1.5)	2	(2)	—	2.5	2.5			
5..	1.5	—	2	(2)	2	2.5			
6..	—	1.5	—	2	(2)				
7..	—	1.5	1.5						
8..	(1)	—	1.5						
9..	1	—	*object width* always $= \frac{\textit{image width}}{n}$						
10..	1	1							
20..	(0.5)	—	*Lens separation* always $= \frac{\textit{Eye separation}}{n}$						
25..	—	0.5							

The figures in the same horizontal line as the number of the magnification give the focal length of the lens to be used, while the corresponding *image distance* is given in the top line vertically above the lens figure. To find the lens required for an image magnified four times at 20 in., we look vertically down from *image distance* 20, and horizontally from magnification 4. The lens required is 2 in. When the lens is exactly correct to formula the figure is enclosed in brackets. In these cases the *object distance* need not be calculated, but is simply found by dividing the *image distance* by the number of the magnification. In the above case, for instance, the *object distance* will be 20 ÷ 4, or 5 in. In general, however, if the worker wishes to avoid trouble, it will be necessary to calculate both *camera extension* and *object distance* from the two formulæ obtained for that purpose, and this is easily done.

$$\textit{Camera extension} = F(1+m), \text{ where } m = n \times \frac{1}{\frac{x}{4}+1}$$

$$\textit{Object distance} = F\left(1+\frac{1}{m}\right)$$

$\frac{x}{4}$ will always be a whole number. Therefore $\frac{1}{\frac{x}{4}+1}$ will be a simple fraction. Multiply this by n, the number of the magnification, and we get m. Put this value of m into the above formulæ, and we have the dimensions required. In the case just considered, where $x = 20$, $n = 4$, $F = 2$: $m = 4 \times \frac{1}{5+1}$, or $\frac{2}{3}$; *camera extension* $= 2\left(1+\frac{2}{3}\right)$, or 3.33 in.; and *object distance* $= 2\left(1+\frac{3}{2}\right)$, or 5 in., which in this case, since 2 in. is exactly the correct focal length, agrees with the value found by simply dividing x by n. It will be seen from the table that the 2-in. lens gives a very useful series of results, many of which are exactly accurate. As already stated, this table is drawn up on strict lines, and the gaps in it may be filled by the use of the lens indicated immediately above or below the spaces without serious loss of accuracy.

For natural size images a 3-in. lens can be used for all distances of the image from 16 in. to 48 in. inclusive unless where very rigid accuracy is required, while a 3.5-in. lens will cover all distances from 30 in. practically to infinity. For images on a reduced scale a 3-in. lens will give all values of n from 0 to $\frac{1}{2}$ at 12 in., and all values of n from 0 to 1 at from 16 in. to 24 in. inclusive. No second lens, therefore, will be needed for this kind of work.

We will now imagine the photographer about to undertake some task by the aid of the table and the two formulæ set out above. The first remark that must be made deals with the artistic considerations that will influence his choice of *image distance*. If his object is 8 in. wide he can show its natural size at 16 in. where *image width* (set down immediately beneath the *image distance* in the table) is 10 in. But it will probably be much better to choose the 20-in. distance for the image, where *image width* is 12.5 in., as this will leave sufficient room on each side for the proper arrangement and display of the object. Or he can show it on the reduced scale of $\frac{1}{2}$ at 12 in., when it will occupy only 4 in. out of the available *image width of* 7½ in. given at this distance. Similarly, if his object is 2 in. wide, he can show it multiplied three diameters at 12 in., but it will be better to choose 16 in. where there is more room. It is not necessary that a small object should be enlarged, provided that its surroundings are properly arranged, as it will simply mean that the central feature of interest in the image will only occupy a small portion of the field—a circumstance which very often has an attractive effect. The worker must exercise the same artistic restraint here as that which prevents him from filling the whole width of, say, a half-plate negative with the photograph of an object which he desires to show in a pleasing way. The first thing, therefore, that the worker must do is to run his eye along the line giving *image width* until he sees a figure amply big enough to give his object room to be properly seen when presented on the chosen scale. Let us suppose, then, that he has an object 2 in. wide, and that he decides to show it multiplied three diameters at 16 in. The table tells him that the lens required is 2 in., and that this is exactly correct to formula, so that *object distance* will be 16 divided by 3, or 5.33 in. The *object width*, or distance between verticals, in all cases will be *image width* divided by n—in this case 10÷3, or 3.33 in. This gives enough room for the arrangement of his 2-in. object. *Print width*, which never varies from the tabulated value, will be 2 in., while *lens separation*, or shift to be given to the camera, will be 2.33÷3, or .78 in. Only one dimension remains to be calculated, namely, *camera extension*. The value of m will be $3 \times \frac{1}{4+1}$, or .6, and *camera extension* will therefore be 2 (1+.6), or 3.2 in. It will be useful to remember that m indicates the ratio of negative to object, or gives the scale of the negative as compared with natural size.

It is taken for granted that the worker has carefully read the practical hints given in connection with the seven detailed experimental cases tabulated earlier. He will then only have to set up his verticals at 3.33 in. apart, adjust the *camera extension* and *object distance* by the lengths found above, and test on the focussing screen the accuracy of the distance between the images of the verticals, which must exactly agree with the *print width* of 2 in. given in the table. If the exposure formulæ are worked out it will be found that for a 1 in. critical depth of focus the stop used should be $F/28$, and that its effective value will be $F/45$, so that this case presents no difficulty. Using this stop, not more than 0.33 in. of the object should be at the near side of the verticals; this, magnified three times, will give the 1 in. image depth in sharp focus at the near side of the principal plane; the remainder of the image will lie at the farther side and will also be critically sharp to a distance of 1 in., and reasonably sharp to a total depth of 2 or 3 in. behind the plane.

We take one more example of a different kind, where n is fractional. Some object, about 30 in. wide, is to be presented on a reduced scale near the eyes—say at 16 in.—in order that its modelling and general conformation may be more clearly seen. (This would seem to be the chief reason why a reduced image may sometimes be desirable.) If n is taken as $\frac{1}{4}$, the image of the 30-in. object will be 10 in. and will quite fill the *image width* available at 16 in. It will be better, therefore, to take n as $\frac{1}{4}$ or $\frac{1}{5}$ —say the latter. The *object width*, or distance between verticals, will then be 10 x

or 50 in., which gives plenty of room for arrangement. The value of m will be $\frac{1}{5} \times \frac{1}{4+1}$, or $\frac{1}{25}$ in. Camera extension, with 3 in. lens, will then be 3 $\left(1 + \frac{1}{25}\right)$, or 3.12 in.; *object distance* will be 3 (1 + 25), or 78 in. *Print width* is given by the table as 2 in. Lastly, *lens separation*, or camera shift, will be 2.33×5, or 11.65 in. If the exposure formulæ are worked out it will be found that the indicated stop for 1 in. depth has the enormous value of $F/2.9$, and that this is practically the same as the effective stop, $F/3$. Great depth of focus and very rapid exposures therefore become possible when the image is reduced. In this case, since $n = \frac{1}{5}$, 5 in. of the object may extend at the nearer side of the verticals. This 5 in. multiplied by $\frac{1}{5}$ will then represent the 1 in. of the image lying at the nearer side of the principal plane. The use of a smaller stop proportionately increases these figures. The exposure data must, however, in such cases be calculated from the formulæ given in Table II.

The great extent of the *lens separation* required in the last example might seem inevitably to lead to distorted perspective, and to result in an image so deformed as to be out of all likeness to the original object. This, however, will not be the case. The perspective effect will certainly be considerably increased because of the small scale of the image and its nearness to the eyes—this, in fact, is the reason for reducing the image; but no matter how small may be the scale, or how wide the consequent *lens separation*, there will be no distortion. A cube, correctly photographed in accordance with the working formulæ, will always remain a cube, and a sphere a sphere. Technical and artistic success in near distance images does not depend at all upon whether they are enlarged or reduced from the object. The danger lies in the fact that the eyes are so sharply converged at these distances that each eye may have a too one-sided view of the image, or that there is not sufficient common ground in both prints, and a very unpleasant effect is produced. As far as possible, the left and right views should not present different facts to the observer, but rather the same facts differently disposed, so that the coalescence of the two may make the whole clear, and allow the points of the image to fall into their proper relationship to each other. In almost every case there will be unavoidable obscurations, and parts of the image visible to one eye will be hidden from the other; but these obscurations, which are sometimes regarded as essential to the perspective relief of the image, are really defects, which it must be the photographer's care to make as few and inconspicuous as possible.

The following table assembles the whole of the working formulæ in their general form, available for use with any stereoscope, and in the order in which they will demand attention.

TABLE II.

Working formulæ giving accurate results by direct printing from the negatives obtained in the camera.

x = distance of image; n = degree of magnification or reduction of the image; f = focal length of stereoscope lenses; OO' = separation of centres of stereoscope lenses; F = focal length of camera lens used; d = depth of focus, or distance of critically sharp definition before or behind the principal plane of the image (plane of *image distance*). S_x = normal separation of eyes when looking at an object at distance x.

1. *Image width* $= OO' \frac{x}{f}$.

2. *Object width* $= \frac{\text{Image width}}{n}$.

3. Focal length of correct camera lens $= \frac{xf}{x + (n+1)f}$

$\left(\text{Ratio of negative to object} = m = n \times \frac{f}{x+f}\right)$.

4. *Object distance* $= F\left(1 + \frac{1}{m}\right)$ when F is any lens.

$= \frac{x}{n}$ when F is exactly correct by formula 3.

5. *Camera extension* $= F(1 + m)$ when F is any lens.

$= x \times \frac{f}{x+f}$ when F is exactly correct to formula.

6. *Print width* $= OO' \frac{x}{x+f}$

7. Exposure formulæ:

Diameter of stop $= \frac{x \pm d}{1200} \times \frac{x}{n} \times \frac{1}{d}$ when F is correct.

F number of stop $= nd \times \frac{1200}{x \pm d} \times \frac{f}{x + (n+1)f}$ for any lens.

Effective F number of stop $= nd \times \frac{1200}{x \pm d} \times \frac{f}{x+f}$ for any lens.

NOTE.—$x - d$ is to be used when d is at the nearer side of the principal plane, and $x + d$ when d is at the farther side.

8. *Lens separation* (camera shift) $= \frac{S_x}{n}$. (For values of S_x see Table I.)

H. C. BROWNE.

FORTHCOMING EXHIBITIONS.

February 11 to 25.—Scottish Photographic Salon. Particulars from the Secretary, James F. Smellie, Braehudon, Allanshaw Street, Hamilton.

February 14 to 17.—Exeter Camera Club. Particulars from C. Beauchamp Hall, Hon. Exhibition Secretary, Exeter Camera Club, 7 St. Denys, Bellevue Road, Exmouth.

February 18 to March 4.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 65, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 25.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 1, Gresham Street, London, E.C.2.

March 15 to 25.—Welsh Salon of Photography. Latest date for entries, March 3. Particulars from the Secretary, H. G. Daniel, 153, Penylan Road, Cardiff.

March 16 to 31.—Leytonstone and Wanstead Camera Club. Latest date for entries, February 28. Particulars from the Secretary, Charles Worman, 1, Cowworth Road, Leytonstone, London, E.11.

March 27 to April 1.—Dennistoun Amateur Photographic Association. Latest date for entries, March 14. Particulars from the Exhibition Secretary, Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

March 23 to April 1.—Hackney Photographic Society. Latest date for entries, March 11. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 3 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 24 to May 13.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Anger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Mr. Percy Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 16 to October 25.—Royal Photographic Society. Latest date for entries, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 30 to February 4.

APPARATUS.—No. 3,066. Photographic developing and printing apparatus. A. Cigarini.

PLATES AND FILMS.—No. 2,922. Photographic dry plates, films, etc. P. W. Collins.

CAMERAS.—No. 3,118. Cameras. P. W. Maxwell.

DAYLIGHT DEVELOPMENT.—No. 2,886. Daylight developing and/or fixing apparatus for photographic films. F. Nourse.

REFLEX CAMERAS.—No. 3,227. Foldable photographic reflex cameras. B. Foulkes-Winks.

RELIEF IMPRESSIONS.—No. 3,048. Obtaining photographic impressions in relief. F. Nisot.

PROJECTION METHOD.—No. 2,754. Projecting photographic images. K. T. Barlow.

CINEMATOGRAPHY.—No. 2,750. Means for obtaining relief effects in motion pictures. E. Castant.

COLOUR CINEMATOGRAPHY.—No. 2,746. Manufacture of multi-colour screens, films, or plates, for natural-colour cinematography. J. Camiller and A. Hay.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FILM-DRYING APPARATUS.—No. 173,919 (October 27, 1920). The objects of the invention are (1) to dry any number of films at the rate of one every 30 seconds, which is even faster than films can be conveniently squeegeed and clipped ready for suspending (2) to be able to place fresh films in without interfering with

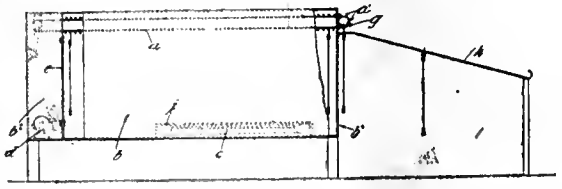

Fig. 1.

those already drying; (3) to take out dried films without interfering with those still drying; (4) to remove dried films so as to do away with an assistant.

A cupboard contains a single moving band for each row of prints being dried, this band being provided with hooks for the reception of detachable clips to which the films are affixed, and a means for automatically detaching the clips and collecting the dried films.

The invention will be described for a cupboard about 15 feet long and 6 feet high.

A short distance from the top is horizontally placed a travelling belt a with hooks a^1 placed every two or three inches, so that approximately sixty or more films will fill the entire length of cupboard.

One end b^1 of the cupboard b, which will be called the exit, is open to allow dried films to pass out, and at the bottom of the

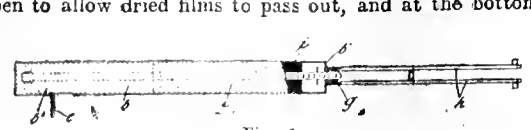

Fig. 2.

cupboard commencing about 2 feet from the exit end b^1 are electric heater units c arranged to spread over about the next 6 feet, and to give a constant temperature of about 95 deg. in the cupboard.

At the admission end b^2 is placed an electric fan d, drawing cold air in at the exit end b^1 over the heater units c past the wet films and out again. Near this end is a fairly narrow door e to allow wet films to be placed on the belt hooks.

It is obvious that this door being open will not upset the temperature of a long cupboard, and hence films can be placed on the travelling belt a at any time without upsetting the drying of others. The fan d is preferably at the bottom of the cupboard, and, as the bottom ends of the films are the wettest, this moisture is removed quickest on account of the warm air being drawn quickly past them, and so even drying is ensured.

Figs. 3 and 4 show a preferable form of film clip: f represents the side arms to the clip, and f^1 the eye of which engages the hooks on the belt.

When the dried films reach the exit end b^1 it is necessary to detach them from the travelling belt a to prevent their being

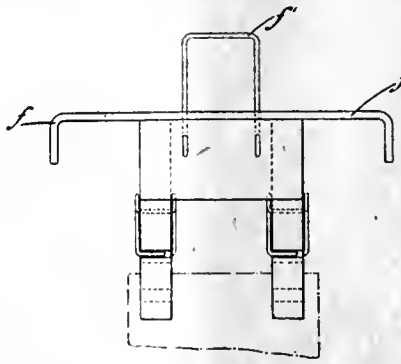

Fig. 3.

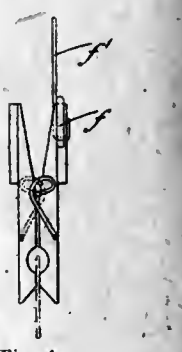

Fig. 4.

carried round the pulleys over which the belt is travelling. This is effected by the film clips catching a bar g which prevents their being carried further by the belt a, and allows and forces them to clip off the back of the belt hook.

The side projections f on the clips drop on to inclined bars h down which the films slide and remain in batches ready for unclipping when convenient.

The belt is driven at any convenient speed, e.g., at the rate of one foot in two minutes, so that 120 films can be dried in one hour, and continuously.

The cupboard is or may be wooden framing, lined completely with any suitable material, and the electric heater units are protected by wire gauze i to prevent an accidentally falling film touching any heated surface.—John Willis Gray, 82, Westborough, Scarborough.

PANEL ENVELOPES.—A correspondent, writing in reference to the ban placed by the G.P.O. upon these envelopes for overseas trade, says: "It was the Madrid Conference that condemned these useful invoice envelopes unless the window formed 'an integral part of the envelope,' the latter pattern being almost entirely of foreign manufacture, and rarely, if ever, used here. The trouble, however, is being overcome, for a British firm of manufacturers (John Dickinson and Co.) have introduced envelopes which conform strictly to regulations, the window in the new pattern being an integral part of the envelope."

HISTORICAL PORTRAITS.—The "Times" announces that the London Library has just received the gift of a collection of engraved portraits and views, estimated to number 50,000, which almost at once puts it on a level with the Print Room of the British Museum. It was formed by the late Mrs. Fraser Baddeley, a life-long collector, and has been presented to the London Library through Dr. Hagberg Wright by her son, Mr. J. F. Baddeley, in memory of his mother, the author. The collection is especially rich in historical portraits, including British and foreign leaders, statesmen, men of letters and science, the Church, and the stage. In London views the collection will probably prove to be one of the most extensive in existence. It is proposed to have the whole of the collection arranged in volumes, the portraits in alphabetical order similar to that of Mr. O'Donoghue's great catalogue of those in the British Museum. The London views will be arranged topographically on similar lines to those in the Croce collection.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 14, Mr. F. F. Renwick in the chair.

The programme of the meeting arranged by the Scientific and Technical Group, first included two papers by Professor The Svedberg, which were read by Mr. Toy.

In the first paper, "The Reducibility of the Individual Halide Grains in a Photographic Emulsion," Dr. Svedberg described experiments by which he had taken photo-micrographs of the silver halide grain after exposure to light but before development. He had used, for the photo-micrographic illumination, light from an incandescent lamp filtered through double layers of Ilford tricolour red filter and then through Wratten A filter, the combination passing light between 650 and 725. Using the Ilford red-sensitive Special Rapid panchromatic plates, the exposures were not more than two minutes. An emulsion of silver iodo-bromide, prepared by Mr. Renwick, when examined in this way, showed that the percentage of developable grains is not greater when the grains are closely packed together. Other experiments were made in which the sensitiveness of the grains to light was reduced by means of Deensitol. It appeared from the results that no transfer of silver ions takes place from the unaffected to the developable grains, even over extremely minute distances.

The second paper, "On the Relation between Sensitiveness and Size of Grain in Photographic Emulsions," concerned the theorem that there may be emulsions of silver bromide consisting of grains of equal size and shape, but having different degrees of sensitiveness; and, *vice versa*, that emulsions differing in the size and shape of the grains may be of the same sensitiveness. Dr. Svedberg dealt with this question from the mathematical and experimental standpoints. On the assumption that in the light-affected grain there are small centres distributed through the grain, he had calculated by the mathematical laws of chance the percentage probability for the occurrence of a certain number of centres in a given grain. From this theory, he had proceeded to investigate an emulsion prepared for him by Mr. Renwick in which the grains were of almost spherical shape and approximately equal in size, and had found that within reasonable experimental error the centres in light-affected grains were distributed according to the laws of chance. The same conclusion was reached in respect to emulsion exposed to X rays. The paper was a further contribution to the investigation of the ultimate causes which account for the characteristic action of light upon a dry plate.

The papers, or rather the second one, aroused an animated discussion, one speaker declaring that whatever the photographic importance of Dr. Svedberg's observations, the communication was the most important one on the physical nature of light which had been published for a hundred years. It appeared that Dr. Svedberg had shown the existence of a definite physical quantum of light. Dr. Slater Price, while paying a tribute to the importance of the results in the theory of the action of light on emulsions, and also to the author's dexterity in dealing with such problems, thought that more quantitative data were required before the results could be wholly accepted.

Mr. Hickman pointed out that in investigating the action of light on silver bromide grains they assumed either the action of a homogeneous agent on a heterogeneous substance, or, alternatively, the action of a series of discontinuous pulses on a homogeneous surface. He did not think that Dr. Svedberg's results were decisive one way or the other.

Mr. Fry agreed, and Mr. Renwick, while expressing his admiration for the paper, thought that too much emphasis should not be laid on the obtained agreement between experiments and a mathematical formula.

A paper by Dr. S. E. Sheppard and Mr. A. P. H. Trivelli, dealing with the same subject, was taken as read.

Then Mr. R. E. Hickman rose behind a battery of apparatus to describe an optical method of testing plate washers and to give a demonstration of some washing devices. With much humour and in a full vein of engaging candour, he explained that in conjunction with a fellow student, Mr. Spencer, he had been engaged for many months on an investigation of the laws which governed the removal of hypo by washing from gelatine films. The papers of Eder and Warwick which had dealt with this subject were a partial consideration of it. He had started by defining the maximum quantity of hypo which could be left in a film without possibility of harm in the course of time to a given density of film. He gave the series of chemical equations on which this calculation was based, and then proceeded to describe the experimental method which had been used in investigating the degree of speed, completeness, and uniformity with which hypo was washed out by washers of various kinds. In doing this he had sought for a coloured substance which behaved similarly to hypo, so as to replace by a visual or photographic test the necessity of making chemical determinations of the amount of

hypo left in or removed from a film. He had found that pure tartrazine behaved in this way, and all the tests brought before the meeting were based on the removal of the yellow dye from films which had been dyed in it. Roughly speaking, the dye was removed at about one-tenth the rate of that at which hypo was washed out, but it had the great advantage of allowing want of uniformity to be seen and also to be photographically recorded by making a print, through a suitable light-filter, on gaslight paper from the partially washed negative. Adopting this method, Mr. Hickman showed the great irregularities exhibited as regards removal of dye from a single plate when washed in a dish, grooved tank, or by various methods of allowing water to fall directly upon it. He showed that mere soaking was highly inefficient; it was necessary to have a stream of water circulating at considerable pressure in all directions over the surface of the film. He had constructed what he called a "river" washer, in which plates were laid between two low weirs so that they were subjected to a constant stream of water automatically kept at a depth of about a quarter of an inch. He also had devised another most ingenious washing appliance, which he called a "circulator," and which consisted of an arrangement of tubes connected to a water supply one part of which directed a stream of water round and round in a dish and intermittently siphoned off the water delivered by the other part. It could be simply attached to an ordinary developing dish. He showed models made both in glass and metal. Incidentally to his work on the washing of plates he had also devised a most ingenious rocker, which gave an irregularly excentric movement to a platform on which a dish could be laid. It consisted of two semi-spherical rubber bulbs, which were automatically inflated alternately, with the result that the dish was slightly tilted first one way, then in another, in a series of movements which constantly varied in all directions.

The most entertaining paper was followed by a demonstration of these appliances, which kept members crowded round the table until a late hour.

Votes of thanks were accorded to the authors and readers of papers.

CROYDON CAMERA CLUB.

The annual meeting was held last week and a good deal of fun extracted out of what is usually a dull affair. The formal proceedings were short, for the club has made it a practice largely to dispense with votes of thanks to separate individuals, big-bugs and lesser fry being lumped and sugared together.

In briefly reprimanding members for their re-election, the president, Mr. John Keane, and the hon. secretary, Mr. J. M. Sellors, both dwelt strongly on the necessity of new blood in their respective offices, and were the only two in the room of this opinion. Mr. F. Ackroyd still controls the finances, which are in healthy condition.

Inquiries as to what had become of the circulating portfolio elicited the fact that it had been lost sight of for ten months or so. No concern was expressed at the loss of the contents, but the portfolio itself is of some value. It was resolved that the matter be placed in the hands of a member who is on the staff of Scotland Yard. Will the present holder kindly note?

A discussion then arose between the "wets" and the "dry-hards" as to whether the sustenance of guests should be debited to general expenses or to the refreshment account, as is the present practice. Mr. Reynolds pointed out that those members who failed to patronise the side-table and appreciate the lectures escaped any liability, which seemed hardly fair. The matter was ultimately allowed to drop.

For some inscrutable reason summer outings are almost an unknown quantity in the Club, with the exception of the Easter excursion. This is emphatically not what it should be, and another trial is to be made to see if members will respond. Mr. Walker kindly consented to act as excursion secretary.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held Monday, February 6. Present: Mrs. MacKay, Miss Bertram, and Messrs. J. Campbell Harper, Norman Thomson, John Thomson, E. D. Young, William Fergusson, W. B. Hislop, George Balmain, W. J. Hutcheson, George Laing, and P. S. Moffat, Mr. J. Campbell Harper, President, in the chair.

The Secretary submitted the report of the Committee appointed to fix minimum prices for commercial photography. The President stated that the Committee had given this matter their most earnest and anxious consideration, and had endeavoured to grapple with this difficult problem by fixing the minimum prices on what was considered a reasonable, as well as a remunerative, basis. He was convinced that the scheme which they had evolved would go a long way towards the solution of their difficulties, and would be of great value to members in guiding them to make a fair and remunerative charge for commercial work. The question of the prices, with the recommendations, were thereafter freely discussed by the meeting, and the following amplification was unanimously agreed to be made to the latter:—(1) "That a 20 per cent. reduction may be allowed for further views on the same subjects taken in the studio," and (2) "If more than twelve views were ordered at the same time, a special price may be quoted by the photographer." It was also discussed whether the Society could make it compulsory on each member to adhere to the minimum prices. It was pointed out that the Society had no machinery wherewith to enforce their resolutions, but that the prices fixed were recommended merely as a guide to members as to what it would cost to do the work at a fair and reasonable return. Mr. George Balmain, seconded by Mr. Fergusson, moved that the minimum prices for technical photography, apart from portraiture, recommended by the Committee to the Society for the guidance of its members, with the amplification above stated, be adopted, and this was agreed to. It was resolved by a majority to agree to the publication of these prices, which are as follows:—

FOR ONE COPY OF PROOF.

	Outside.	Studio.	Unmounted and Untoned.	Rough Mounted.	Large Mounted.
	£ s. d.	£ s. d.	s. d.	s. d.	s. d.
15 × 12.....	1 10 0	1 2 6	5 0 each	6 3 each	7 6 each
12 × 10.....	1 0 0	0 15 0	4 0 ,,	5 0 ,,	6 0 ,,
10 × 8.....	0 17 6	0 10 6	3 0 ,,	4 0 ,,	5 0 ,,
8½ × 6½.....	0 12 6	0 7 6	2 0 ,,	2 6 ,,	3 0 ,,
6½ × 4¾.....	0 10 6	0 5 0	1 0 ,,	1 6 ,,	2 0 ,,

Time allowed in studio, half-an-hour; exceeding that time, at the rate of 5s. per hour or part thereof. Time allowed for outside work, for first plate 1½ hours, and half-an-hour for every subsequent negative; time in excess of this, at the rate of 5s. per hour. Extra negatives: Studio work, no reduction, but a 20 per cent. reduction may be allowed for further views on the same subjects taken in the studio; 20 per cent. reduction for extra negative on outside work. If more than twelve views are ordered at the same time, a special price may be quoted by the photographers. Stopping out backgrounds, or other extra work on negatives or prints, to be charged at not less than 5s. per hour. Charges for panchromatic work to be left to the discretion of the photographers.

The next question before the meeting was whether it was desirable to hold a Scottish Congress in Edinburgh in 1923. The members were unanimously in favour of the Congress, and also of a photographic exhibition being held. It was urged that the exhibition would prove a great attraction, and would be an effective way of deepening the interest in photography, especially when it was combined with lectures by prominent photographers and a trade exhibition. An effort would be made to secure a large representation of photographers from Newcastle and all over Scotland at the Congress. By this means it was thought that a greater interest would be stimulated between photographers, and by the exchange of views an impetus would be given to the profession of photography. It was agreed to appoint a research committee, consisting of Mr. J. Campbell Harper, Mr. E. D. Young, and Mr. Moffat, to consider the preliminary details and to report at the next meeting.

It was agreed that each photographer be allowed to make his own arrangement for the holiday season.

Mr. Fergusson, in moving that an addition of £3 3s. per annum be made to the remuneration paid to the Secretary, alluded to the time and attention given by him to the affairs of the Society. Mr. E. D. Young seconded, and this was approved of. Mr. Lowson, in thanking the meeting, stated that this mark of appreciation of his services was quite unlooked for. It had always been a delight to him to render any service to the Society whose affairs he had very much at heart.

A vote of thanks to the chairman concluded the business.

ROYAL INSTITUTION.—The Friday evening discourse on February 24, on the "Age of the Earth," will be delivered by Professor John Joly, F.R.S., of Dublin, whose interest in photography has been shown in other directions than the Joly colour process.

News and Notes.

American Portraits for London.—In connection with the Photographic Fair to be held at the Royal Horticultural Hall, Westminster, from May 1 to 6 next, an exhibition is being arranged of examples of modern portraiture by professional photographers in the United States. The organisers of the Fair are offering a thirty-guinea silver cup for the best group of portraits of not more than six pictures. The veteran and accomplished portraitist, Mr. William Crooke, of Edinburgh, has kindly consented to judge the exhibits. Photographers in the United States are invited to contribute towards making this exhibition representative of the best work which is being done in their country. Pictures must not be framed, but may be mounted, although the latter is optional. If, however, prints are mounted the mount should preferably be 15 by 12, 20 by 16, or 25 by 20 inches (in no case larger than the latter), and whenever possible should be white or of light tone. Unmounted pictures will be suitably mounted by the organising committee, and all accepted pictures will be shown under glass. All pictures for the exhibition should reach the organising secretary, Photographic Fair, Royal Horticultural Hall, London, on or before April 10. We have no doubt that many leading portrait photographers in the United States, who from time to time have been glad of the opportunity of showing collections of British work, will avail themselves of this opportunity of making a collective national exhibit for the interest and advancement of the many professional photographers who make it a custom to visit the Photographic Fair.

Messrs. Griffins, Kingsway, London, W.C.2, send us a list of professional goods offered at greatly reduced prices in their annual stocktaking sale. These include mounts, furniture, frames, backgrounds and many professional sundries. Messrs. Griffins also issue a monthly chemical price list, obtainable only by bona-fide professional photographers.

Stabilising the Amidol Developer.—In reference to the article last week, Mr. J. G. F. Druce writes that there is an error in the equation on line 3, column 2 (page 81). The right-hand side of the equation is given twice. Actually it should read:—

$$HO.C_6H_3(NO_2)_2 + 8Sn + 16HCl = HO.C_6H_3(NH_2)_2 + 8SnCl_2 + 4H_2O.$$

Faversham Institute Photographic Society.—An exhibition will be held at the Lecture Hall, East Street, Faversham, from April 5 to 8. There is an open class, in which two gold and three bronze medals will be awarded. Mr. J. Ogden, principal of the Sidney Cooper School of Art, will judge. Prospectus and entry from Mr. W. H. Evernden, 126, West Street, Faversham.

A Keen Motorist-Photographer.—At the Birmingham Police Court last week a motorist-photographer was fined £20 for driving a car to the danger of the public. He was alleged to have crashed into an approaching car, which was smashed, the driver being injured. After the accident he mounted a motor-coach near by, and took snapshots of the wrecked car.

British Industries Fair.—The eighth British Industries Fair will be held from February 27 to March 10 next, and will again consist of two sections, one for heavier metal goods at Birmingham and the other at the White City, Shepherd's Bush, London, W. Over 250,000 invitations to buyers in the United Kingdom have been issued and nearly 50,000 to overseas buyers. Almost every industry in the country, with the exception of textiles, will be represented in the Fair.

Summer Time.—A Bill was presented last week by the Home Secretary providing that Summer Time shall begin at midnight on the night of the last Saturday in March (or the last Saturday but one in March when the last Saturday is the day preceding Easter), and shall terminate at midnight on the night of the first Sunday in October. These dates are fixed in agreement with France and with Belgium, in order to obviate the inconveniences which have been experienced in the past through Summer Time beginning and ending on different days in the different countries. The Bill makes the arrangement, which has hitherto been carried out under Orders in Council, a permanent one.

The Lay Press.—Amateur photographers, who rely, even in part, upon the lay press for technical information, must sometimes have remarkable experiences. A London evening newspaper recently gave the following valuable formula for compounding Farmer's reducer:—

Solution A.	Potassium ferricide	1 oz.
	Water	1 oz.
Solution B.	Hypo	2 ozs.
	Water	1 oz.

It is stated that the silver image of a photograph will gradually disappear when immersed in a mixture of two parts of A and one of B.

The Right Way in Photography.—The right way is a long, long way, if one is to draw any inference from the cover of this new instruction booklet of Messrs. Burroughs Wellcome's, which represents a view of snow and ice in the Antarctic. Such, however, is not the intention of the publishers, who have simply taken the opportunity to use one of the many photographs developed by Mr. Ponting on the South Polar expedition with Tabloid "Rytol." The booklet is a brief instruction manual in development by time and tank with Rytol and in the use of the chromium intensifier. It contains a table of half-tone reproductions showing the latitude in exposure by time development, and also includes an actual negative, one half of which has been intensified with chromium. One of the most helpful manuals issued by Messrs. Burroughs Wellcome, and that is saying a good deal. It is obtainable free on application to Snow Hill Buildings, London, E.C.1.

Mr. Pirie MacDonald, of New York, whose cards of Christmas and other seasonal greetings are invariably little doses of stimulant (we hope the word will not inspire vain regrets at his fireside), recently sent us the photograph which we reproduce. Mr. MacDonald is on a fortnight's holiday in the Adirondack Mountains, the resort for winter sports in the northern part of New York State, where the temperature may be 20 degrees below zero. However, the keen, dry air and the continuous sunshine are together a tonic which gives the visitors to the heights the energy which carries them through the frequently trying heat of the New York summer.

History Cinema Films.—An interesting experiment in the teaching of history by means of the film is now being undertaken in the United States under the supervision of the Yale University Press. According to the "Times" correspondent, a hundred reels of film depicting American history are to be produced by a new organisation called "The Chronicles of America Picture Corporation," which has been organised for the purpose. These reels will be grouped into coherent phases of American history, and every important stage in the development of the country is to be dealt with. The whole work will be carefully supervised by the Yale University Press. Under the direction of the Yale University Press preliminary work for the production of these films has now

been taking place for two years. It is hoped that these "Chronicles of America Pictures" will serve as a useful help to teaching. They are not intended in any way to supplant existing methods of instruction, but to assist them. Above all, their aim is to inculcate ideas of good citizenship.

THE HISTORY OF FALLOWFIELD'S.—Few firms in the photographic trade can look back upon so long a period of continuous activity as that of Jonathan Fallowfield, of 146, Charing Cross Road, London. Established in the year 1856, in Lower Marsh, Lambeth, by the late Mr. Fallowfield, it quickly took a leading place in the supply of requisites for the wet-collodion process, and for the other then current photographic methods. Since that time it has preserved a record of enterprise in the supply of the latest requisites for all branches of photography. Messrs. Fallowfield have recently had the happy idea of bringing together in their window a collection of bygone price lists and advertisements, of great interest to those who have a liking for looking back upon the steps which photography has traversed. Perhaps the most notable of these are the drawings by Carruthers Gould, which were made for the advertisement of the "Facile" hand camera, introduced by the firm in the year 1889. For the "Facile" may, we think, be said to have been the real pioneer among hand cameras. A glance through the "B.J. Almanac" for 1890 shows that the common idea at that time among manufacturers was to put a camera of the stand pattern in a box, as much for the purpose of disguising it as for the facilities which are now universally associated with the hand type of camera. The "Facile," on the other hand, was a quite different conception, the plates being carried in an upper magazine, and being transferred after exposure to the lower part of the apparatus. It is interesting to see in Messrs. Fallowfield's window some framed P.O.P. prints from "Facile" negatives still, to all appearances, as fresh and bright as when they were made. The 1890 catalogue of Messrs. Fallowfield, which contains a detailed description of the "Facile," is a volume of 430 pages, on the back cover of which is reproduced one of the most famous of Sir Carruthers Gould's drawings, namely, that of Lord Randolph Churchill waiting at a corner for Mr. Gladstone to come within the field of the lens.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY.—In addition to the usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, the directors have declared an extra dividend of 7½ per cent. upon the common stock, all payable on April 1 to stockholders of record on February 28.

LEGAL NOTICES.—At an extraordinary general meeting of the Photo Printing and Publishing Co., Ltd., a resolution was passed to the effect that the company be wound up voluntarily, and that Charles Edgar Willbourn, 120, Carlton Vale, Kilburn, N.W.6, be appointed liquidator.

Notice is given that the creditors of the Langham Studio, Ltd. (in voluntary liquidation), are required, on or before March 7, 1922, to send in particulars of their debts or claims to Kenneth Alfred Edgar Moore, chartered accountant, Thames House, Queen Street Place, E.C.4.

At an extraordinary general meeting of the members of the Lonsdale Process Engraving Co., Ltd., held at the registered offices, 27, Chancery Lane, W.C.2, a resolution was passed to the effect that the company be wound up voluntarily, and that Mr. Charles Glyn Read be appointed liquidator.

NEW COMPANIES.

TURNER & HOW, LTD.—This private company was registered on February 2, with a capital of £500 in £1 shares. Objects: To take over the business of a photographer and photographic dealer, carried on by F. Turner, at 67, Park Lane, Leeds. The first directors are: F. Turner, 9, Ashville Avenue, Cardigan Road, Leeds; R. H. How, 119, Cardigan Road, Leeds. Qualification: 10 shares. Remuneration as fixed by the company. Secretary: E. Spence. Registered office: 67, Park Lane, Leeds.

C. A. BURDETT (CHEMISTS), LTD.—This private company was registered on January 30, with a capital of £300 in £1 shares. Objects: To acquire the business carried on at 14, Regent Street, Dawlish, Devonshire, and to carry on the business of chemists, druggists, opticians, dealers in photographic supplies, etc. The first directors are: H. F. Stapley, 45, Craven Road, Hyde Park, W.; C. A. Burdett, 14, Regent Street, Dawlish. Qualification: 1 share. Registered office: 14, Regent Street, Dawlish, Devon.

INDUSTRIAL INTELLIGENCE, LTD., has been registered as a company limited by guarantee, without a capital divided into shares. The objects are: To promote publicity and propaganda of all kinds, especially such as may be calculated to foster production, manufacture and trade in and between all parts of the British Empire and other countries; to promote and assist the production and distribution of literature, printed matter, photographs, illustrations and advertisements, and billposting of all kinds; to organise meetings, lectures and exhibitions; to establish and conduct commercial agencies, etc. The company is to be governed by a council of not more than six members, two being elected annually at the general meeting and one nominated by each of the following bodies:—The Federation of British Industries, the British Electrical and Allied Manufacturers' Association, the Cable Makers' Association, and the British Engineers' Association. The first members are: Llewellyn B. Atkinson, Alster, Little Hampden, Great Missenden, Bucks., electrical engineer; Roland T. Nugent, 21, Egerton Gardens, S.W.3, director, Federation of British Industries; D. A. Bremner, 9, Rossetti Garden Mansions, Chelsea, S.W., director, British Engineers' Association; and D. N. Dunlop, Onslow Village, Guildford, director, British Electrical and Allied Manufacturers' Association. Each of the above-mentioned organisations shall be entitled to become the first "Association" members without election, and the signatories to the Memorandum of Association the first "ordinary" members. The registered office is 24, Chancery Lane, W.C. The file number is 179,507.

FILM SPEEDS.

To the Editors.

Gentlemen,—Is it not time something was done to indicate more accurately the speed of films? Those who use plates, can rely (more or less) on the "H. & D." or "Watkins" figures, printed on the containing box. In the case of films the only guides are such words as "speed films," "as fast as the fastest," "super speed," "double instantaneous," and so forth, vague in the extreme and reminiscent of the early days of the "dry plate." Cannot film makers conform to the modern practice, and give speed figures which would, at least, be of some value for the purpose of comparison? The recent introduction of several new roll-films seems to make a departure from the present slip-shod manner of suggesting speeds particularly desirable. Even the amateur is now largely "educated up" to the point at which a knowledge of the speed of emulsions is a matter of vital interest.—Yours faithfully,

LYULPH LUMLEY.

Automobile Association, Coventry Street, London, W.
February 10.

CO-OPERATIVE ADVERTISING OF PHOTOGRAPHIC PORTRAITURE.

To the Editors.

Gentlemen,—It is with great interest that I read your article "More Business in Portraits." This co-operative advertising appeals to me strongly, as I believe it would stimulate portrait photography to a marked degree.

This matter has received my careful consideration, and I feel convinced that it is within the bounds of practical politics.

I was so impressed with the value of co-operative advertising that some years ago I submitted a scheme to the Council of the P.R.A. They, however, advised me that my scheme was not practicable.

This matter, I think, can with advantage be aired in the correspondence column of your paper.—With compliments, yours faithfully,

Canterbury, February 13. W. FISK-MOORE.

INVENTIONS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—After reading Mr. Ives' letter dated January 7 I am tempted to ask, What is a discovery and what is an invention?

The analysis of light and the isolation of its elements, the investigation of the part these play in relative admixture or combination in producing the visible object in respect of the form and colour, are in the domain of physical discovery. The utilisation of reflectors, screens, prisms, or other optical apparatus to effect separation of the elements of light, and their recombination so as synthetically to reproduce the visible object, are in the domain of invention. But neither the general optical knowledge nor the well-known appliances in themselves constitute the invention in which they are employed.

Their employment may be common to many independent inventions; their particular and specific application as a means of effecting a required result is the actual invention. Both the optical knowledge and appliances used in tricolour photography long antedate the various apparatus employed to secure photographic colour reproduction. The fundamental ideas underlying all current practice are by no means new. They were not originally announciated by Mr. Ives, and Mr. Ives' application of them by no means exhausts their utilisations.

Some twenty years before Mr. Ives applied for his patent M. Louis Ducas Du Hamon had used these fundamental ideas in a patent for "Improvements in photography in colours and in apparatus for that purpose."

But they established no claim to originality, and least of all to an exclusive proprietorship in their employment.

Mr. Ives' invention of the Kromskop was an application of the principle, not less ingenious because previously used. As a practical fact the Kromskop was a viewing instrument, not a taking camera, and calling it a camera did not make it one.

While expressing my deepest admiration for Mr. Ives' invention, which gave results in viewing that never have been, and probably never will be, surpassed, it advanced nothing in overcoming the essential difficulties in the construction of a taking camera. The production of negative images of identical size and focus, correct as to colour values, practically correct as to relative densities, and produced simultaneously, was not, so far as I am aware, even attempted in the Kromskop. Other patents for similar inventions, all using the same principle, were granted immediately before, simultaneously and subsequent to my own application. I do not know if any of these have succeeded practically in doing what it was the object of my invention to accomplish, but I believe I can safely assume that neither Mr. Ives nor anyone else has ever produced in the Kromskop, even though fitted with plate holders as Mr. Ives suggests, three simultaneously exposed negatives capable of being used for correct colour reproduction.

Mr. Ives says: "Making tricolour cameras register is one of the simplest problems I have had occasion to attack." So far as this applies to the Kromskop, I agree it is very simple. In the first place, the positives which produce the images may be printed from colour screened negatives of identical size, produced either simultaneously or successively. The images of these are superimposed in an instrument such as the Kromskop adjustable both for the position of the "colourgram" positives and the reflectors, and with these conditions it is a simple matter to register the images where the eye exercises a continuous check over their movements.

It is quite otherwise in a taking camera, where a number of factors have to be co-ordinated in a structural adaptation which necessarily is fixed and permanent.

I claim that I have in a practical manner, in my single exposure tricolour camera, devised a means that will, under correct conditions of light and with suitable sensitive plates, fulfil the conditions above set out, and which no proper use of language could describe as "a patent on the Kromskop."—Yours faithfully,

EDWIN T. BUTLER.

26, Craven Park, Willesden, London, N.W.10.

EXPERIMENTS WITH FOLIO-BROM.

To the Editors.

Gentlemen,—In the practice of photography it is sound wisdom to stick to one plate and one paper, at any rate it is a sure way to avoid failure.

When I opened the first of three packets of the Folio-Brom stripping negative paper, which I bought recently, I was doubtful. However, I put them in my slides, same as a plate with a cardboard backing, and then marched out to expose them on a paying job. In the dark-room I just took the ordinary developer, pyro-soda, with a few drops extra bromide, and to my surprise they came up like a good, sound, dry plate. I fixed, washed, and dried them as instructed, and when dry they stripped from their support quite easily, with good detail and good density for bromide paper.

But, by some means or other, one of the films got wet and cockled badly, and was quite useless for printing. After a little consideration I cleaned a whole plate glass and put the film in a dish of clean water, and with a little dodging I at last got the film flat on the glass. At this stage the film is so delicate that it requires careful handling. When right on the glass, take a roller squeegee, and carefully roll out the surplus water with blotting-paper. Put up to dry, and you will then have a 7 by 5 negative instead of a half-plate.

The negatives can be easily intensified with mercury and ammonia, and when dry will leave the glass clean and flat.—Yours truly,

HENRY HOLMAN.

Banff, February 8.

PRICES OF PHOTOGRAPHIC MATERIALS.

To the Editors.

Gentlemen,—We are writing to ask you to kindly bring forward the question of the current prices of photographic plates and papers. We are consequently losing business owing to the high prices we are compelled to charge for our work, and in order to encourage a revival we shall have to very much reduce the price.

We find that no reduction in price has been made on bromide papers since February 10, 1920, and in plates since March 12, 1921.

We are large purchasers of papers, gelatine, and silver salts for other purposes, and we find that the cost of these three articles, which are the main ingredients of our sensitising materials, has come down enormously since the above-mentioned dates, and it is high time the plate and paper manufacturers reduced their prices accordingly. Everything else we buy in a business covering many departments has been reduced several times since the above dates, and surely the plate and paper manufacturers must, in their own interest as well as ours, come into line.—Yours sincerely,

ENTWISTLE, THORPE AND CO.

42, Deansgate, Manchester.
February 13

PHOTOGRAPHY AT THE ROYAL WEDDING.

To the Editors.

Gentlemen,—Owing to my association with the late Sir Benjamin Stone in obtaining the Abbey photographs of His Majesty's coronation ceremony, I was interested in your article in to-day's issue of the "B. J." regarding the photographic arrangements for the forthcoming Royal Wedding.

At the time of the coronation His Majesty was most anxious that the solemnity of the service should not be disturbed by unsightly cameras, therefore, both camera and operator had to be screened.

After experimenting for quite a month before the event, it was found that the fastest plate procurable at the time would require not less than five seconds exposure, owing to the very meagre

amount of light filtering through the grimy stained-glass windows in the Abbey.

It is a matter for congratulation that British plate makers have greatly improved on the speed of plates since then.

The arrangements for supplying the Press with prints for publication purposes in the shortest possible time will, I think, take some beating. The first photograph of the proceedings (procession of the crown jewels) appeared in the newspapers which were being sold in the streets at the moment the King was leaving the Abbey, after the proceedings. Special trains were chartered to take the prints to the North, in order that the northern newspapers could publish the principal views simultaneously with the London papers the following morning.—Yours faithfully, WM. RANSFORD.

Belsize Park Studio, N.W.3.
February 10.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. J. H.—We thank you for your letter, which we have sent on to the inquirer.

N. N.—We do not know of any practical method for printing out on bromide paper and fixing the prints. We daresay some kind of an image can be got by soaking the bromide paper in potash nitrite solution and printing out. But whether the image so obtained will stand fixation in hypo we do not know. We very much doubt if it will.

P. F. R.—About the best method of rendering paper negatives semi-transparent is to iron pure paraffin wax into them with an ordinary domestic iron. Another method is to soak in a mixture of castor oil and alcohol (or ether), the ether or alcohol evaporating and leaving the oil in the paper. Both methods are troublesome and rather messy, and, moreover, will not give the degree of transparency obtained with the thin paper of the envelope which you send owing to the presence of the somewhat opaque baryta coating on the emulsion paper.

O. B. E.—There have been a considerable number of patents for processes of stereoscopic cinematography, or rather for producing a species of pseudo-relief by cinematograph projection. We think if you wish to ascertain what has been done the only course for you is to examine these specifications, for which you would require to trace the subject-matter by means of the classified abridgments of patent specifications, published by the Patent Office, 25, Southampton Buildings, London, W.C.1. On page 416 of the current "B. J. Almanac" you will find a brief account of some recent inventions.

H. H.—There is little to choose between the lean-to and ridge roof style of studio, but on the whole we think the latter preferable it will look better inside, and as the angle of the glass will be more acute there is less likelihood of leakage or lodgment of snow. For so narrow a studio it will be very desirable to have a height of 8 ft. to the eaves, this will only just allow a standard 8 x 8 background to be used With lower sides you would find the angles coming into the picture when taking groups. For artificial lighting two 1,000 and one 2,000 c.p. half-watt lamps should be sufficient.

L. S.—We do not think there is any way of producing identical focus for the apparatus you describe under the two conditions, owing to the alteration of the length of rays from the original by passage through the prism. This alteration will be slightly different for every different degree of reduction. It might be possible to draw up a table for the setting of the lens front and back frame of the camera corresponding with different degrees of reduction and according to whether you use the prism or dispense with it, but we should think this would be an unsatisfactory system in practice and liable to lead to negatives defective through unsharpness.

S. G.—For toning with Schlippe's salt prints are bleached in the customary mixture of ferri-cyanide and bromide, as used for sulphide toning, and after a few minutes' washing are treated with a solution of 5 grs. Schlippe's salt in 10 ozs. of water. The worst of this process is that it is rather erratic. The Schlippe's salt should be of the best quality and of comparatively fresh make. Even then it does not keep very well either in the solid state or in solution. If you add about 20 drops of strong ammonia solution to the above Schlippe's toning bath the tone is somewhat darker and a purer warm brown. We think this is a better tone than the reddish, and is obtained with rather more certainty. Many people now, we believe, prefer to get a red tone by toning a sulphide toned print in a bath of sulphocyanide and gold. Instructions are contained in a booklet which Messrs. Wellington & Ward send free on application.

W. T.—(1) It looks as though the formula you are using does not contain a sufficient quantity of water, at any rate for use under conditions where the temperature is liable to fall below 60 deg. We advise you to make up the formula with double the quantity of water, using double the quantity of this stock solution in making up the working developer. A developer of this kind, which has once thrown down a deposit of developer base, is not very easily got into working condition again. All you can do is to add, say, an equal bulk of water and keep the mixture somewhere where the temperature does not fall, say, below 75 deg. F., shaking or stirring the mixture occasionally. (2) Bromide prints ought not to alter in the way you describe, if they do we should look for insufficient fixation as the cause. Water-colours, if of good quality, ought to be quite permanent for months in very much brighter weather than that prevailing at the present time of year.

L. L.—The arrangement entered into between yourself and the editor appears somewhat vague. You appear to have agreed to do the work and supply prints on the speculative basis that you should be paid your share of the reproduction fees paid by other newspapers. If that is so, there would be no objection to your sending prints for reproduction, but your "customer" (we mean the editor) would then, of course, ask for his share of the profits Really the matter ought to be decided by the answer which you can make in your own mind to a question such as this:—Did or did not the editor give you an order to take the subject, for which order you expected to be paid by him, and in respect to which he understood he would have to pay? If you did get such an order then the copyright is solely the property of the editor, and he can do what he likes with prints which you supply to him at a price. But if there was no such order, and in the absence of any other definite arrangement, the copyright is yours, and you can do what you like with the photographs as regards canvassing for reproduction fees and taking them. We are afraid we cannot write more plainly from the information supplied.

The British Journal of Photography.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3225. Vol. LXIX. FRIDAY, FEBRUARY 24, 1922. Price Fourpence.

Contents.

SUMMARY

In a paper from the Eastman Research Laboratory Mr. E. R. Bullock describes some very interesting observations on the convection current set up in solutions during the action of bleaching solutions, and also in the operation of the fixing bath. He describes an ingenious means of rendering these currents visible, and shows how they account for certain irregularities in the action of solutions. A further conclusion is that a plate is fully fixed as soon as the white silver bromide has disappeared. (P. 110.)

In a leading article we refer to the method of investigation which has been followed by Mr. Bullock. (P. 107.)

In the further portion of their paper on the rapidity of a lens Messrs. Vivian Jobling and E. A. Salt describe a modification of the appliance for the direct measurement of the relative working aperture or F. No. of a lens. (P. 108.)

Formulæ and working details have been given by Mr. W. T. Wilkinson of an improved form of the wet collodion process in which the iodide in the collodion is replaced by a mixture of chloride and bromide. (P. 112.)

The practice of photo-micrography is very greatly simplified to the beginner by means of an attachment to the ordinary camera, yielding excellent results up to magnifications of about 100 diameters. (P. 106.)

Particulars of the committees entrusted with the organisation of the congress and exhibitions to be held by the Professional Photographers' Association next September will be found in a report of a council meeting on page 118.

Bulgaria having subscribed to the Berne copyright convention the 1911 Copyright Act has been extended to Bulgarian nationals by an Order in Council. (P. 119.)

The first issue of a French journal of theoretical and applied optics has been published. (P. 119.)

Publication of the Austrian journal, "Photographische Korrespondenz," has been suspended for the present year. (P. 119.)

A quartz electrical resistance in a metal casing forms a convenient means of bringing fairly large quantities of developing solution quickly to a required temperature. (P. 105.)

Constructional details of a printing frame for making a considerable number of reproductions from a single negative are given in a recent patent specification. (P. 115.)

In a paragraph on page 105 we refer to the convenience of the vertical camera for occasional copying both of flat originals and small objects.

Such very large apertures as $f/1.5$ can seldom be used on outdoor subjects with lenses of considerable focal length, such as 12 in. or so, or even with those of shorter focus on reflex cameras. (P. 106.)

EX CATHEDRA.

A Developer Heater.

We see mentioned in the French photographic papers an appliance which has been put on the market by a Besançon firm for bringing considerable bulks of developer or fixing solution, such as are used in the handling of amateurs' film negatives, to a suitable working temperature. The appliance consists of an electrical resistance made of quartz and mounted in a cylinder of nickelled metal. It is provided with terminals which are connected by a length of flexible cable to any ordinary lamp holder. On the current being switched on and the solution stirred with the heater the temperature is quickly raised. In fact, according to the description in our French contemporaries, the appliance suffices to bring a moderate quantity of water to nearly boiling heat in about ten minutes, and thus serves the additional purpose of providing hot water in making up stock solutions in quantity without the inconvenience of heating the water over a gas burner. A miniature appliance of this kind, for bringing a few ounces of water to boiling heat, is a familiar article in the electrical shops, and possibly the larger heater which we have described is made in this country, although we have not heard of it.

* * *

A Vertical Copying Camera.

For the odd jobs in the way of making copies of old photographs and other originals which are brought to a studio by customers, the convenience of a vertical arrangement of a special camera deserves to be given more attention than seems often to be the case. A copying outfit of this type may be kept at hand ready for use, and then needs only to be placed where it will get the light from a side window. Illumination under these conditions is particularly good, and if the camera is provided with one or two extra lens panels, permitting the use of several objectives of different focal lengths, almost any ordinary degree of reduction can be obtained without trouble. The horizontal easel on which originals are made may be a flat board covered with cork lino, to which a mounted or unmounted photograph or print is quickly attached with one or two glass push pins; or it may be a glass plate on which the original is laid and kept flat by placing a second glass plate upon it. The latter plan is of particular convenience in using the apparatus for photographing small solid objects—coins, geological specimens for example—since it allows of any appropriate background being provided by arranging a suitable sheet of mounting paper a few inches below the glass easel. In this connection it may be useful to refer to the employment of a ground glass easel for the reception of such specimens, the ground glass forming the top of a box containing some electric lamps by which the "background" can be given such strength as to obviate blocking out, whilst, at the same time, details in the photograph may be almost completely washed

Long-Focus Lenses. The purchaser, whether amateur or professional, of a long focus lens for outdoor use, is apt to cast envious eyes upon the instruments of large aperture, such as *f*/4.5, which are catalogued by the opticians. Those, however, who have had much experience in the use of ultra-rapid lenses of considerable focal length relatively to the size of the plate which is to be covered, know that the opportunities for using such lenses at the full aperture are comparatively few and far between. For the sake of depth of focus most subjects require the aperture to be reduced to *f*/6, *f*/8, or even still smaller, so that the money which is spent on the extra cost of obtaining the very large aperture can be employed only in infrequent circumstances. Generally speaking, for stand cameras for outdoor subjects, there is very little utility in purchasing a lens of focal length 12 inches or more which is of larger aperture than *f*/6 or even *f*/8. If the lens is also to be used for portraiture in the studio, the circumstances are of course somewhat different, and the facility of short exposures justifies the expenditure on a large maximum aperture. Even when we come to lenses of shorter focal lengths employed on smaller cameras the same considerations largely hold good. For example, a 7-inch *f*/4.5 lens on a quarter-plate reflex is certainly a de luxe fitting which on occasion can render valuable service. But in regular use its owner will find himself almost invariably compelled to set the diaphragm down to *f*/6 or *f*/8, and perhaps on the whole will hardly consider himself repaid for the greater cost, weight and bulk of his instrument.

SIMPLE PHOTO-MICROGRAPHY.

Photo-micrography can hardly be described as a popular branch of photography, although there is an active Photo-micrographic Society, and probably a good many workers in the provinces who do not belong to that body are fully qualified by competence and keenness for membership. Unfortunately, apart from the fact that advanced photo-micrography requires a good deal of patience and skill on the part of those who practise it, there is now one particularly solid reason why it does not appeal to any but the comparatively few, namely, the costliness of high-class apparatus. Where the higher powers are in question, as they must be, for instance, in a large proportion of medical, biological, and botanical work, not only is it essential that the microscope itself and the eyepieces and objectives should be of first-rate performance, but also the photographic arrangements must, if the best results are to be attained, be of a special description in order to secure adequate rigidity, accuracy of alignment, and satisfactory illumination. Even when only moderate powers are attempted, and an ordinary camera is mounted for photo-micrographic use upon a simple baseboard, with a plain bullseye as condenser and incandescent gas as illuminant, the outlay is considerable, if a microscope has to be procured at the price now ruling for such instruments. There are microscopes and microscopes, of course, but a big hole is made nowadays in twenty pounds by a first-class stand with inclinable tube, a couple of oculars and objectives of low power, and a few simple accessories..

This, we repeat, is unfortunate, for photo-micrography is an extremely interesting and useful pursuit enabling photography to be profitably applied in a number of fresh and often really important directions. Moreover, an immense amount of good work can be done at powers very much lower than those required for purposes of special scientific research, and without any wide knowledge of microscope technique. It is probably safe to say that the great majority of specimens such as are usually mounted for microscope observation belong to one of two classes, namely, those which cannot be satisfactorily examined with powers under × 500, and those for which powers ranging from × 20 to × 150 are amply sufficient. For the former, the photo-micrographer must have a microscope and a suitably-mounted camera in order to obtain really good results, but for objects such as can well be examined with 1-inch or ½-inch objective and an appropriate eyepiece a simple attachment to the camera is quite practical, and one or two arrangements of this sort have, in fact, been designed. An up-to-date attachment, which is described and illustrated in another column, is that put on the market by Messrs. James Swift & Son, whose microscopes have a world-wide reputation, and who, we may be sure, would not have given their name to the instrument under allusion unless it satisfied exacting requirements in the way of precision and efficiency. It will be specially noted in connection with this simple little instrument that there is no optical departure from the system pursued with microscopes of the highest class. Not only are ordinary oculars and ordiuary objectives employed, but the separation between them is that at which they are commonly placed in Swift microscopes designed for purposes of the most minute and elaborate research.

A photographer who possesses an attachment of this kind cannot, of course, hope to obtain photo-micrographs of bacilli and other almost invisible objects, but it is surprising what he can do with very little trouble and at times when ordinary photography is out of the question. Undoubtedly, it is preferable to prepare one's own slides, but for those who have not the time or inclination to do so, plenty of interesting objects are available at a low cost, and often a single slide of, for instance, a complete insect will yield material for half-a-dozen good photo-micrographs. Very few accessories, too, are wanted. A bullseye condenser is useful, though not essential, and artificial light is better than daylight, because it is more stable. In photo-micrography there is no satisfactory rule by which exposures can be calculated, and test exposures are even more necessary than in enlarging. After a little practice tests with electric light, acetylene, or incandescent gas can be made very easily, which will suffice to indicate pretty accurately most of the exposures required to be made for a batch of similar subjects, even though the latter have to be photographed at different powers. As regards manipulation, work with an attachment such as that under allusion is an extremely simple matter. The instrument is screwed into the camera front just as if it were an ordinary lens, a specimen slide is placed in position on the stage with the illuminant behind it, and focussing is effected by means of the sliding jacket or outer tube of the attachment. By holding the circular stage between the middle finger and thumb the object can be sharply focussed, even when a ½-inch in place of the standard 1-inch objective is used. To the back of the stage a fitting can be fixed, enabling a sub-stage condenser or iris diaphragm, or both, to be used, if desired. Without these additions, however, a great deal of interesting photo-micrography can be done, and for the scientific and technical worker the instrument provides a very simple and efficient means of examining the graininess of different negatives, effects of intensification, etc. It goes without saying that, where only visual observation is needed, the attachment can be used in the hand, but many may welcome the facility afforded of obtaining graphic and accurate records of the relative "fineness" or "coarseness" of various brands of plates for purposes of comparison.

Photo-micrography, like telephotography, may never become widely popular, but, like its antithesis, it has many claims to attention, and it has the advantage that no special conditions of weather or atmosphere are needed to produce good results. Simplification of the means employed is a step in the right direction, and, now that a firm of unquestioned repute has placed on the market a comprehensive instrument which any intelligent possessor of a rigid camera with a moderately-long extension can use with success, many may be induced to take up this branch who formerly regarded it as either outside their inclination or beyond their reach.

WATCHING SOLUTIONS AT WORK.

In view of the popularity which the so-called "stand" method of development is winning for itself, a peculiar interest attaches to the communication by E. R. Bullock, of the Eastman Kodak Research Laboratory, which appears in our present issue. Mysterious markings and variations in density have probably come within the experience of most professional photographers, especially those who cater for the development and printing requirements of the amateur. Any work which leads to a smaller proportion of unsatisfactory negatives being obtained, particularly when it is felt that the undesirable features have been introduced whilst the plates or films were in the hands of the professional, will prove to have a value which can be computed in pounds, shillings and pence, quite apart from its intrinsic value as a research leading to the acquisition of new knowledge. Mr. Bullock, like many other observant operators, noticed peculiarities and irregularities in the action of certain bleaching baths, and, being so fortunate as to have facilities at his disposal for probing the matter, he satisfied himself that as is usually the case, the sensitive material was not to blame. He was also able to satisfy himself that agitation of the bath prevented irregularities of the action. "Why go further?" the practical photographer might be tempted to ask. "Why not print the instructions to agitate the bath, or to reverse the developing tank, in block type on the instruction sheet, and leave it at that?" The answer which the researcher would undoubtedly give would be "Because one should know how and why." The discovery of the how and why is usually a tedious business, and, if the manner in which the results of a research are presented is oftentimes the reverse of inspiring, it should be remembered that not only is research itself a very "slow" game, but our judgment should be tempered by the consideration that the training which makes a researcher leaves very little time for him to cultivate a novelist's literary style.

When we look more closely into the matter we see, however, that in its essentials even the driest account of a research is fascinatingly interesting because of its simple and logical steps. In the present research, what was more natural, for example, than to assume that if a strip of film hanging in a "still" bleaching bath is bleached less rapidly at the lower end than at the top, the decrease of the action may be due to exhausted solution from the top of the film streaming down the surface and, as it descends, rushing the fresh solution out of the way? This would lead to the conclusion that the exhausted solution is specifically heavier than the fresh, and again it would be natural to try the effect of using a solution which would yield specifically lighter products when it acted, in the hope that a reversal of the direction of increased action would be shown. These things were tried by Mr. Bullock, and Figs. 1 and 2 afford striking proofs in black and white of the accuracy of the reasoning. The photographer need not worry himself over such matters as "catalysis of the reaction," which are mentioned in the report, for even the most erudite amongst the chemists and physicists of the day do not pretend to understand "catalysis." All that need be remembered is that if for any reason the heavier or lighter modified solution has *not* lost its attacking power, a falling off in the attack of the ascending or descending stream will not be noticed—a statement which is self-evident, and the truth of which was confirmed by tests with an acid solution of persulphate.

One striking feature of the research is that of the bleaching of two strips of film, one above the other, each strip, it is stated, showing the stream variation effect, independently of its position. One would naturally have expected that the exhausted stream from one strip of film would have affected the rate of bleaching on the next strip. From the context it appears as though the mere cutting of the film causes a sudden break in the continuity of the ascending or descending stream. Assuming, as one should, the correctness of the observations, we would suggest that the break in the effect is due to the slight curl of a hanging strip of cine film suspended in a solution which causes the gelatine of the emulsion to swell. This curl would deflect the exhausted stream possibly to such an extent that it would pass along the reverse side of the film immediately above or below. It is not clear whether this "break" was noticed in the case of gelatine emulsion on glass plates situated one above the other in the bath—it is only referred to in connection with films—and perhaps at a later date Mr. Bullock will find an opportunity to clear this point up.

The desire to see with the physical eye as well as with the mind's eye, is just as strong in the case of scientists as it is in that of the man in the street who readily enough subscribes to the picture newspaper and visits the cinema. This desire has in the present instance led to the discovery of an exceedingly simple and neat way of demonstrating, during its actual existence, the presence of the "stream" and has, moreover, enabled measurements of solubilities of certain compounds to be made with a reasonable degree of accuracy. After experimenting with such substances as lamp black, sulphur, etc., it was noticed that cotton fibres, when present in the solutions being investigated, were sufficiently visible and specifically light enough in weight as to afford an indication of the "stream" or convection current, with the added advantage that the rate of travel of the "stream" also became discernible. Other things being equal, it is obvious that the rate of the "stream" will afford an indication of the rate of the reaction which is occurring between the solution and the image on the plate or film. The elegant way in which these observations were utilised to investigate the solubility of silver selenocyanide is detailed in the paper.

When we turn to that portion of the communication dealing with the existence of convection currents in "still" developing and fixing tanks, we are on ground over which most present-day photographers will find little difficulty in following the investigator. The experiments with the fixing baths are particularly interesting in that they support the view that the solubilisation of the sensitive silver salts does not take place in such a way as to form first an insoluble double compound. This opinion has already been expressed by MM. Lumière and Seyewetz, and leads to important conclusions with regard to the cause of fading by sulphurisation of bromide prints. Altogether, the communication is worth careful perusal by the worker who wishes to understand the inner mechanism of his everyday operations.

SOME FACTORS CONCERNING THE RAPIDITY OF A LENS.

(*Concluded from page* 95.)

The pinhole and bromide paper method is familiar to most, and is useful for ascertaining the value of the full opening, but is not convenient for determining a smaller standard stop where the full opening is not in the series. A piece of ground glass pressed against the lens hood can be substituted for the bromide paper.

Mr. Welborne Piper suggested a simple plan of direct sighting along a scaled block of wood laid on the lens hood,

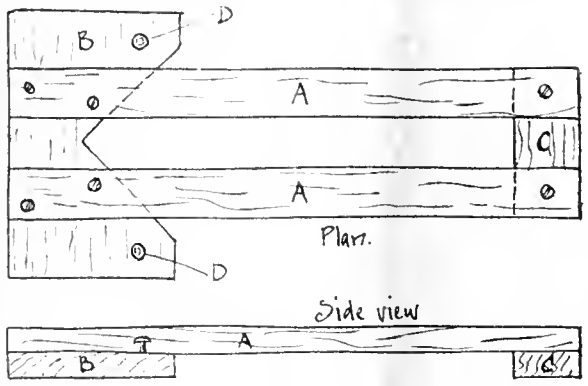

Fig. 1.

but some who have tried it have not found it quite satisfactory, it not being easy to sight along a line drawn on a flat surface. It is, however, only fair to add that our old member suggested additions for more accurate reading.

One of us (Mr. Jobling) has devised a modification which is easily sighted, and reads with great accuracy, as it is

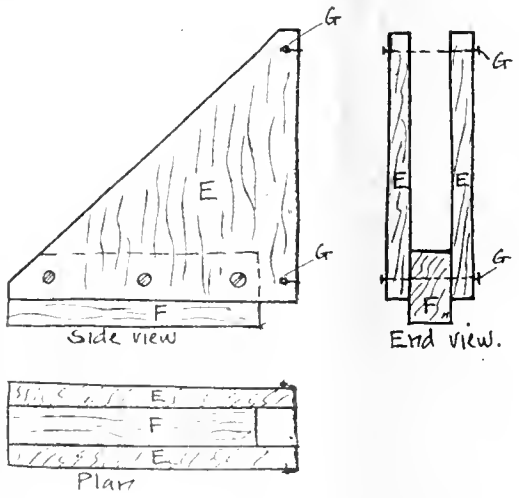

Fig. 2.

self-centreing. Its construction will present no difficulty to any woodworker of moderate skill.

The component parts are illustrated by sketches in figs. 1, 2, and 3, the complete apparatus in position on a lens hood being shown in fig. 4.

Fig. 1 is made up of two strips A, about 7 in. × ¾ in. × ¼ in., which are both secured to a piece B, about 4 in. × 3 in. × ¼ in., and made rigid by a short connecting piece C at the other end.

The complete guide rests on the lens hood, which fits into the V-grooves in B, an elastic band passing round the hood and hooking on to the pins D. The guide rails A are thus centred upon the hood. The sight carriage, fig. 2, slides upon the rails A, the guide F fitting between them.

Two side pieces E, about 3½ in. × 3½ in. × ¼ in., are secured to a spacing piece F, which is about 3 in. × 1 in. × ¼ in. Four pins, G, in the sides, E, serve to hold cross "wires" of fine silk thread.

The remaining part of the apparatus (fig. 3) is a cursor of bent tin or other metal, the width, W, being about 1¼ in. The space between the flanges is such as will give a sliding fit over the rails A.

The apparatus is used in the following way:—Assuming the rails to be in position as just described, slide the sighting slide along until the right-hand edge or side of the lens stop is in alignment with the two cross wires. Then bring the cursor up to the vertical faces of the slide, thus recording its position. Next move the slide to the left until the cross wires are in alignment with the other edge of the lens stop, and measure the distance between the cursor and the vertical faces of the slide. This can be done with an ordinary graduated rule. To facilitate the sighting it is advisable to support the lens upon a sheet of glass with a

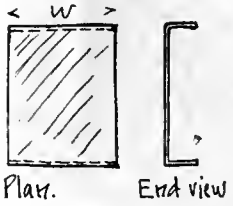

Fig. 3.

sheet of white paper at some little distance beneath, as shown in the illustration. With an apparatus of the sizes given, the effective aperture of small quarter-plate lenses and under, up to large portrait lenses with hoods of 4 in. diameter, can be measured with ease.

For some eyes the distance between the cross-wires may be found too great; in such a case it can be reduced. Viewing them at a fair distance will also be found of assistance. The simpler apparatus devised by Mr. Piper obviously can be combined with the method of centreing described.

There are many methods of ascertaining the focal length of a lens, a simple way only requiring a foot rule and a camera, and doubtless sufficiently accurate for all practical purposes, being described by Mr. A. Lockett in the "B.J." of 1915, p. 411.

So far the factors concerning aperture only have been touched upon in relation to rapidity, but there are several others which it is now generally recognised have an appreciable bearing.

Losses due to absorption and reflection occur in unequal degree; and if the illumination as a whole on the plate is considered, the cutting off of light at its edges by the lens mount varies widely in different types of lenses, and with the focus of the lens in relation to the plate. The latter factor also introduces a variable into the lessened intensity at the margin, due to the plate seeing the diaphragm opening at an angle, or side-ways.

Even the corrections of a lens may play a part, especially

in the rendering of shadow detail. Frequently it happens that shadow detail portrayed sharply may be so faint as only to be barely printable. In such a case a soft-focus (aberrated) lens by spreading the image will reduce the deposit on the negative to the vanishing point, and a void in the print results. Complaints have been made as to the occasional loss of texture in the shadows when using such lenses, and possibly this is the reason.

The losses due to reflection and absorption have been carefully investigated in the past by Mr. H. H. Cheshire and Dr. Zschokke, but the results obtained, broadly speaking, apply only to orthochromatic plates exposed behind a filter, the ultra-violet, violet, and part of the blue being excluded. Although the conclusions arrived at are very valuable and interesting, yet from a practical point of view rapidity in a lens appears to be most essential when the shortest exposures are compulsory, and extreme-speed "ordinary" plates are of necessity employed. Here the transparency of the lens to the actinic rays becomes of prime importance.

Mr. Cheshire estimates for each glass to air surface a loss of nearly 5½ per cent. of the light falling upon it. A land-

Fig 4

scape lens presents two glass to air surfaces; a doublet four, and a triplet six. Assuming a thickness of 5 mms. for each component lens, in round figures the first transmits 89 per cent. of the incident ("orthochromatic") light, and the second and third respectively 79 and 69 per cent. Four and five separated lens systems, respectively 60 and 52 per cent.

These figures speak for themselves, and are sufficiently remarkable; but more striking differences may arise in practice, when an appreciable amount of ultra-violet may be passed by a thin lens, and be almost entirely absorbed by a thicker lens composed of the same, or other glasses.

Many a time has been expressed astonishment at the rapidity of the tiny landscape lenses fitted to vest-pocket cameras, which seems out of all proportion to their relative value of about f/12, and the single shutter speed rarely, if ever, slower than 1/30th second. Also the Cooke f/6.5 triplet has often been referred to here as a relatively fast lens, which probably the thinness and transparency of its glasses account for, the f 6 Aldis sharing this commendation. Doubtless not a few other English lenses are now of equal rapidity, aperture for aperture, but they are many, and comparisons are not so often made as when only a few anastigmats were on the market.

As a contrast to thin lens-systems the Goerz "Dagor" lens may be mentioned with apologies, if any are needed. Despite the combined thickness of the six glasses used in its two triple-cemented elements, it had a great reputation for rapidity, which its aperture of f 6.8 (not always realised) most certainly did not account for. On the other hand, many have been known to express a firm belief in the comparative *slowness* of certain anastigmats apart from aperture.

Unfortunately, the ordinary worker has no way of testing the matter except by general deductions based on actual practice, and no exact values can be assigned. To meet this need it has been suggested that lens makers should indicate the *efficient* aperture in some way.

Mr. Brown, in the articles alluded to, suggests they might supply a co-efficient increasing the F. No. to a greater or lesser extent in comparison with an ideal lens (of perfect correction, and absorbing and reflecting no light) or by comparing one lens with another, but he does not appear very hopeful that any such plan will ever be adopted.

The second suggestion does not seem so practicable as the first, but in any case two co-efficients, at least, would be necessary, one for application when "ordinary" plates were in use, and one when screened orthochromatic plates were employed, as it might well be that one lens, fast for an ordinary plate, might be slow for an orthochromatic one, and *vice versa*. Also, matters would be rendered very complex if other than central rays were considered, and thus would be left, as it is now, any definite information relative to the intensity of illumination beyond a relatively small angle.

With extra-large aperture lenses a rapid falling off of light from the centre to the margins of the plate usually occurs, due to the greater separation of thin components; whilst with many types of anastigmats the components are brought so close together as to afford the maximum uniformity of light over the plate, and they are proportionally the faster. True, a narrow-angle lens, or one with a circle of illumination of diameter not greatly exceeding the diagonal of the plate it is designed to cover, other things being equal, reduces fog due to reflection from the bellows or walls of the camera, and has often been praised for this reason. But as this is necessarily accompanied by an appreciably lessened intensity at the margins of the plate, a lens capable of covering a much larger one than that in use, and fitted with an efficient lens-hood to trap superfluous light, is in most cases to be preferred.

Portrait lenses, perhaps, are the worst offenders as regards non-equality of illumination, a feature, however, which may be helpful in portraiture by subordinating the margins of the picture. The late Mr. J. H. Dallmeyer, F.R.A.S., many years ago gave some instructive figures in reference to the famous f 3 portrait lens. He pointed out that it equally illuminates a central spot of 12 deg. only; at 32 deg. this illumination is reduced to one-half, and beyond this it diminished again until at 52 deg. it ceases altogether. These angular values expressed in inches of circular area for a 3½-in. lens of 12-in. equivalent focal length are (in round numbers) 2 in., 6½ in. and 13 in.

Quite apart from any question of definition, it will thus be apparent that a careless use of the rising or falling front in relation to the more important parts of the subject on the plate, may reduce the full rapidity of a portrait lens there very materially, whilst its judicious employment will retain it more or less.

VIVIAN JONLING.
E. A. SALT.

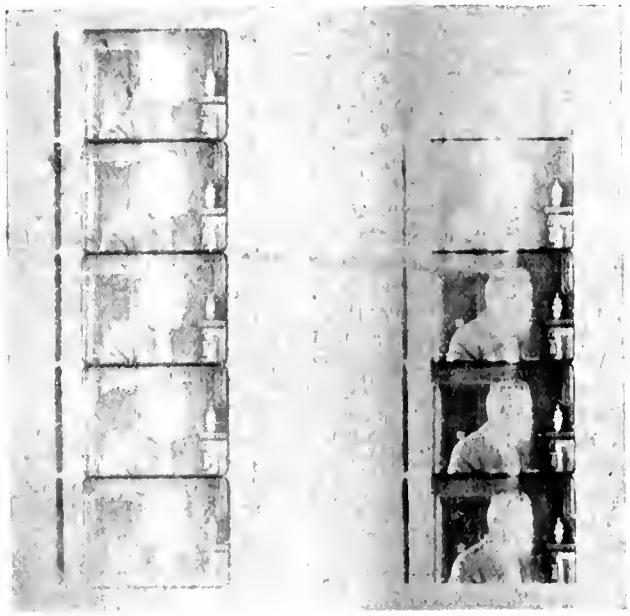
ON CONVECTION EFFECTS IN PHOTOGRAPHIC BATHING OPERATIONS IN THE ABSENCE OF AGITATION.

A Communication from the Research Laboratory of the Eastman Kodak Company.

WHEN a silver image in gelatine on a strip of glass or film support is immersed vertically and then left at rest in a solution of potassium ferricyanide and potassium iodide in a glass tube, it can be seen while watching the course of the bleaching action that the rate of bleaching is greater at the lower than at the upper end of the strip. This phenomenon has now been submitted to an investigation, which, although somewhat hurried and in some respects incomplete, has led to results and conclusions of sufficient apparent definiteness and general interest to justify their publication. As far as the writer is aware, the subject in its general bearing on photographic bathing operations has not been discussed in the literature hitherto, although certain of the facts involved, such as the appearances which arise in stand development, when agitation of the developer or reversal of the tank is omitted, have been described.

The above-mentioned effect has been noticed previously in the Laboratory and attracted the writer's attention recently when bleaching some short lengths of printed cinematograph film in a solution

I. II.



Showing partial action of :—I, Ferricyanide-iodide; II, Chromic Acid Solution.

of potassium ferricyanide 1 per cent., and potassium iodide 0.3 per cent. The first suggestion of a lack of uniformity in the picture was quickly shown to be unfounded; and the effect was obtained equally (1) under various degrees of illumination, (2) when the solution was protected from evaporation, and (3) under the pressure due to a head of 35 ins. of the solution. The effect was also obtained equally with silver images in (1) gelatine on glass, (2) collodion on glass, and (3) gelatine on film support. As the result of density measurements it was found that with glass and film alike the density of a partly bleached (and then fixed) image diminishes continuously from the top to the bottom, the rate of diminution not being uniform, however, but tending to be less in the middle portion than either near the top or near the bottom. (In the illustration, I is a short strip of film picture which has been bleached in ferricyanide iodide solution and fixed.) As regards the magnitude of the effect, it may be mentioned that density measurements of one particular plate, 16 cm. in length, that had been uniformly "flashed," developed, cut lengthwise into two, and one-half then partly bleached by vertical immersion in ferricyanide-iodide and fixed in hypo, showed that the density had been reduced to about 25 per cent. of its original value at a level 1 cm. from the top, and to about 10 per cent at 1 cm. from the bottom.

The magnitude of the effect is influenced, although not very greatly, by the length of the immersed image, being somewhat greater the longer the image. If two or more strips of film are arranged in a long tube, either one strip immediately above another, or with intervals between each strip, and bleached simultaneously, each strip shows the effect independently of its position, and in a degree varying only with its length. A moderate degree of vibration has no appreciable influence on the effect; this was shown by comparative tests in two buildings, in one of which the vibration (due to proximity of machinery) is much greater than in the other. Shaking the tube by hand, or stirring the solution, during the reaction, however, entirely prevents the appearance of the effect.

Passing now to the effect of other halidising (halogenising) bleaches, it was found to be generally true that a bleach (such as ferricyanide-iodide or iodine-in-potassium-iodide solution) which converts silver to silver iodide shows the effect more strongly than one which converts silver to silver bromide. Of the latter, ferricyanide-bromide, permanganate-bromide, chromic acid and bromide, and bromine water were tried; the effect being always found, although less strongly marked. With chloridising (chlorinating) bleaches (such as permanganate-chloride or chromic acid and chloride), the effect was also always found, but in a further diminished degree. The invariability with which these results were obtained, and the regular gradation in the magnitude of the effect when passing from iodide through bromide to chloride, with a variety of images in gelatine on glass or film support, suggested that a consideration of the physical chemistry of the reactions would reveal some simple explanation of the main effect.

It was obvious, on consideration, that the chemical process which (and which alone) is common to all of the above-mentioned bleaching reactions is the union of silver with halogen, that is, with iodine, bromine, or chlorine. The halogen is *lost* by the solution, and *gained* by the image held in the gelatine film, entailing changes (in accordance with known physico-chemical data) of volume and density of both solution and image. Of these changes there is one, namely, the *density*-change of the *solution*, which will give rise to motion in the form of a gravitational convection current. Density being diminished, an upward current will be established along the surface of the film, and will continue throughout the course of the chemical reaction. Provided that the reaction products do not catalyse the reaction, the current must have the effect of accelerating the reaction at the point where it begins (that is, at the bottom of the film), and of accelerating it in a smaller and smaller degree, or of actually retarding it when it has suffered a loss of halogen during its upward progress along the surface of the gelatine film. This is exactly the effect observed; and the explanation was, therefore, regarded as a satisfactory one at this point, and was used as a working basis for arranging new experiments. In the case of a reaction in which the density of the solution *increases*, a *downward* current should be produced, and, provided that the reaction products do not catalyse the reaction, the latter should be accelerated at the top of the film and relatively retarded at the bottom. Again, an increase in the viscosity of the solution should, in general, entail a change in the magnitude of the effect.

It had been found that the magnitude of the effect did not vary very appreciably with the time required just to bleach an image completely at its lower end, provided that this time was of the order of five minutes, and the concentration of the various halidising bleaches used in the comparative tests had been adjusted accordingly. A solution containing chromic anhydride 0.05 per cent. and sulphuric acid 0.2 per cent., was now found to attack the image at about this rate, giving, in accordance with the theory tentatively proposed, a reversed effect, namely, an accelerated reaction at the top of the film, and a relatively retarded one at the bottom. (In the illustration, II shows the partial action of this bath.) It should be stated that not quite the whole of the silver

that is attacked is carried into solution by the action of this bath, a small portion remaining in the image as silver chromate, removable by fixing in hypo. A striking comparison is, nevertheless, shown by using this bath respectively without, and with the addition of potassium bromide to the extent of about 0.5 per cent.; the action being greatest in the former case at the top and in the latter at the bottom. Permanganate-sulphuric acid solution was tried and found to act like the chromic acid-sulphuric acid solution, both as to the direction and the degree of the effect. Persulphate-sulphuric acid gave a comparatively feeble effect in the same direction. In this case,[1] in view of the auto-catalytic character of the reaction,[2] the observed diminution is intelligible, as also, indeed, would have been a reversal of the effect. Silver-dissolving solutions other than these were not tried, as it appeared that the result predicted from the proposed theory had been found without a doubt.

According to the theory, also, an increase in the viscosity of the solution should be accompanied, in general, by a change in the magnitude of the effect. Inasmuch as diffusion as well as convection is impeded by an increase in viscosity and as an impedance of diffusion may increase the effect while an impedance of convection will certainly diminish it, it was not possible to predict the result which would be found. As a means of increasing the viscosity of the solutions without affecting the nature of the chemical process, pure sodium sulphate was added in varying amounts up to saturation to ferricyanide-iodide and chromic acid-sulphuric acid solutions, respectively. After increasing the concentration of the active constituents, to compensate for the general slowing of the reactions, a distinct diminution in the magnitude of the effect was observed when much sodium sulphate was present in the former case, while in the latter there was little or no difference.

Attempts were now made to demonstrate the actual presence of convection currents during the chemical reactions of the two types considered. The first thought was that of adding to the solution some kind of particles sufficiently large to be individually visible, and yet sufficiently small or of sufficiently low density to remain in suspension for at least about five minutes. Lamp-black, sulphur and silver halides were tried, and occasionally a drift of the particles in the direction indicated by the theory was observed, but these substances as used were obviously unsatisfactory for the purpose. Short fibres accidentally present in the solution having been seen to move either up or down the vertically-immersed film, when by chance they had come into its immediate neighbourhood, this suggested the deliberate use of cotton fibres. A small piece of cotton-wool was pulled out by hand and the fibres cut transversely into short lengths by means of scissors. When added to the solution, these short pieces of cotton fibre settled only slowly, were readily visible when brightly illuminated, and showed the position, direction, and duration of the current by their movement. While it is doubtless possible to find other more suitable methods, yet the use of short lengths of cotton fibre in the solution seems reasonably satisfactory for the demonstration of the actual existence of the theoretically-indicated currents. The phenomenon is more striking in the case of an upward than in that of a downward current, for in the former case the particles are borne away from the region into which they are slowly settling by gravitation, travel up the surface of the film and into the solution above it, and then turn in a fountain-like curve and descend at a greater distance from the film.

A method of general application for the demonstration of the occurrence of chemical reactions between images in gelatine films and solutions in which the films are immersed appears, therefore, to be available. It will fail only in the special case of the density of the solution being unaltered by the reaction. The method may prove useful in the investigation of photographic and general chemical problems. One example of its application will be mentioned. Potassium selenocyanide (KCNSe) had been observed at one time by the writer to behave as a somewhat powerful restrainer when added to a developer, and it was surmised that the solubility of the corresponding silver salt was quite small. In order to determine where the solubility lies in comparison with the solubilities of the silver halides, the following experiment was made. Images on cinematograph film were bleached to silver chloride, bromide, and iodide respectively, then immersed vertically in an 0.5 per cent. potassium selenocyanide solution, to which cotton fibres had been added. In the case of the chloride image, an upward current, lasting for about 3.5 minutes, was observed; with the bromide image a relatively very feeble current lasting for at least 5.5 minutes, and with the iodide image no current was seen. Images of silver selenocyanide, as obtained by somewhat prolonged immersion of the chloride images in the selenocyanide solution, followed by washing, were then immersed in an 0.5 per cent. potassium bromide solution: no movement of the cotton fibres could be observed. It is thus apparent that while a reaction is shown between silver bromide and dilute potassium selenocyanide solution, no reaction is shown either in the case of silver iodide or between silver selenocyanide and dilute potassium bromide solution; and the inference is permissible that the solubility (in water) of silver selenocyanide falls between the solubilities of silver bromide and silver iodide.

Passing now to the subject of *stand development*, it is of practical importance to minimise spontaneous convection, and the consequent variation of action at different levels of the immersed emulsion film.[3] (In the case of bleaching reactions the practical question scarcely arises, inasmuch as the reaction is—almost invariably—allowed to proceed to completion; and in the case of the silver-dissolving reactions, these are either carried to completion as in the Autochrome reversal, or under control in a tray as in the persulphate reduction of negatives.) From a consideration of the chemistry of development—broadly speaking, a gain of halogen by the solution—it may be predicted that convection effects do, in general, occur whenever agitation is omitted, not only when the emulsion film is vertical, but also when inclined or horizontal. With vertical immersion, as in ordinary stand development, the current should be downward, causing stronger action at the top than at the bottom of the film, and the effect should be strongest in the development of silver iodide and weakest in that of silver chloride. In order to test the correctness of these conclusions, the following experiments were carried out. Strips from a roll of positive cinematograph film containing a series of uniformly exposed and developed images from one and the same negative image were bleached respectively to chloride by means of a freshly-prepared solution of potassium permanganate, sulphuric acid, and sodium chloride, followed by a clearing solution of sodium bisulphite, to bromide by means of a ferricyanide-bromide, and to iodide by means of a ferricyanide-iodide solution. The bleached strips were in all cases washed for about 20 minutes and then dried, the washing, drying, and subsequent development being carried out in subdued daylight, taking great care that the light-exposure received by each strip should be fairly uniform throughout its length. Three different developers—amidol, MQ, and pyro-soda—were now taken and so diluted that a satisfactory degree of development was effected in about five minutes in the cases of the chloride and bromide images; for the iodide images the developers were used undiluted. Treatment of each of the three kinds of images with each of the three images showed clearly, in seven out of nine cases, a somewhat greater degree of development at the top than at the bottom of the strips; in the other two cases, however, the reverse effect was found. These cases were those of the action of dilute pyro-soda developer on the chloride and bromide images, and the reason for the anomaly was quickly surmised—oxidation is rapid with this developer and the effect of preferential oxidation of the upper portion may preponderate over the convection effect. On diluting the stock developer with 2 per cent. sodium sulphite (Na_2SO_3) solution instead of with water, the anomaly disappeared. It may, therefore, be concluded that during normal stand development a downward current prevails, entailing a greater degree of development in the upper than in the lower portion of the emulsion film. In the case of the iodide films the existence of the current was verified by the cotton fibre method already described; in the other cases, on account of possible complications through uneven illumination, observations were not attempted. It was also not attempted, on account of the time which might be consumed for the satisfactory establishment of the facts, and the comparative unimportance of the result, to compare qualitatively the magnitude of the effect with the respective silver halides. In order to obtain a roughly quantitative estimate of the magnitude of the density differences likely to arise in ordinary stand development without agitation, ordinary bromo-iodide films and plates were given

1. Stratochemical effects are described by Sheppard in a paper to be published on the "Persulphate Reduction Anomaly."

2. H. Marshall, "Action of Silver salts on Ammonium Persulphate Solution," *Trans. Roy. Soc. Edinburgh*, Vol. 33, 163.

3. The influence of stirring on the rate of fixation was investigated by Sheppard and Mees (Investigations, pp. 126-129). Irregularity of fixation-rate was traced to convection currents, and the existence of these has been observed by Sheppard and Davis (in a paper to be published).

a uniform exposure corresponding to a point somewhere in the over-exposure region of the characteristic curve, and then vertically immersed in developers of such dilution that a density of about 2 was obtained in five minutes at 20 deg. C.; for the films an MQ developer diluted with water was used, and for the plates a pyro-soda developer diluted with sodium sulphite solution. The strips taken were about 16 cm. long and about 3.5 cm. wide; and subsequent density measurements showed that the density difference at points 1 cm. from the top and 1 cm. from the bottom amounted in all cases to between 5 per cent. and 10 per cent. A general effect of this magnitude on an image might, perhaps, be disregarded for most purposes, but the local effects in consequence of the juxta-position of high-lights and shadows may occasionally be serious. With horizontal development at rest and the emulsion film up, the reaction products of development will tend to accumulate unduly in the emulsion film and in the lowest layers of the solution; while with the emulsion film *down* over a moderate depth of developer, the reaction products will tend to be removed as soon as formed, and development will be relatively accelerated. In actual comparative trials, using Seed Graflex plates, an image density greater by about 20 per cent. or 25 per cent. with no greater fog was found in the latter case, but development is never uniform, and the method is, therefore, not applicable in practice.

Finally, a few observations were made on the process of fixing. A number of different bromo-iodide emulsion plates were taken, cut into strips, and immersed vertically in hypo solution of such concentration that in each case the plate was visibly cleared in about eight minutes. Cotton fibre having been added, the initial phenomenon observed was a strong downward current, which continued until the greater part of the opacity of the emulsion was removed. At this point it was very apparent that the *upper* portion of the strip was the more transparent. The current now became feebler, and the rate of clearing of the plate much slower than before. At the point of complete clearing a difference of behaviour was noted depending on the brand of plate: in some cases the current appeared to cease somewhat abruptly as soon as the plate was cleared, while in others a feeble downward current could be observed to persist for up to two minutes longer. It seems very probable that the rapid removal of the greater part of the opacity and the simultaneous strong (downward) convection current represent broadly the dissolution of the silver bromide, while the relatively slow removal of the residual opacity accompanied by a relatively feeble current represents similarly the dissolution of the silver iodide. The results tend, moreover, to cast a doubt on the supposition that the sparingly soluble sodium silver thiosulphate ($NaAgS_2O_3$) is formed during the fixing of a bromo-iodide plate or film; and in regard to the theory of this reaction it may be mentioned that it is probable that by mistaken analogy a misapprehension has crept into the photographic[4] literature. For the sparingly soluble thiosulphate having the composition $NaAgS_2O_3$, which was obtained by Lenz in 1841 and by Rosenheim and Steinhäuser in 1900, was obtained respectively by a reaction between hypo and silver nitrate, and one between hypo and freshly precipitated silver chloride; and, on solubility considerations, it does not necessarily follow that this particular double thiosulphate is obtainable also from hypo and silver bromide or iodide in the condition in which these salts exist in the photographic emulsion film. Experiments by Mr. J. G. Capstaff of this laboratory, in 1917, showed, indeed, that in the case of bromo-iodide plates an immersion in the fixing bath only up to the point of complete clearing, followed by a washing of ordinary duration, was sufficient for the practically complete removal of the silver halides, as shown by the absence of a discoloration on treatment with sodium sulphide solution.

Summary and Conclusions.

1. The relatively more rapid bleaching of a silver image on cinematograph film at the lower end of a strip immersed vertically in a ferricyanide-iodide solution was found to be a special case of a general phenomenon, which is seen with all silver images on an impervious support when immersed vertically in any halidising (halogenising) bleach.

2. By theoretical reasoning it was concluded that the above-mentioned phenomenon must be attributed to the effect of the existence of an upward convection current having its origin in the diminution of density of the bleach solution in contact with the image by the chemical reaction which takes place.

3. Silver-dissolving solutions were found to act more rapidly at the upper than at the lower end of a vertically immersed silver image. The actual existence of upward convection currents during the action of halidising bleaches, and of downward currents with silver-dissolving solutions, was demonstrated by the motions of suspended short lengths of cotton fibre.

4. A general method is thus available for the demonstration of the occurrence of a chemical reaction between a solid and a liquid. As an example, it was found that silver bromide reacts with a dilute potassium selenocyanide solution, and from this fact (with others) it was concluded that silver selenocyanide is less soluble than silver bromide, but more soluble than silver iodide.

5. In ordinary stand development (with vertical immersion and without agitation) a downward current prevails, and the degree of development is accordingly somewhat greater near the top than near the bottom of a negative; under usual conditions the density difference due to this cause is of the order of 5 per cent. or 10 per cent.

6. Convection effects during the fixing of a bromo-iodide emulsion seem to harmonise with the view that, broadly speaking, the silver bromide dissolves before the silver iodide. It is probable that immediately after the disappearance of the last traces of opacity during the fixing of a bromo-iodide emulsion the whole of the silver had been converted into the very soluble double thiosulphate.

E. R. Bullock.

Photo-Mechanical Notes.

Bromide-Chloride Wet-Collodion.

Some time ago at the Royal Photographic Society Mr. W. T. Wilkinson read a Paper describing the advantages of a variation of the wet-collodion process, in which the iodide in the collodion is replaced by a mixture of bromide and chloride. We print below the chief part of this communication, and are able to supplement it by some further practical notes on the process which Mr. Wilkinson has written.

The wet-collodion process requires great skill and care to keep it going, but sooner or later silver iodide will give trouble. In making up a new silver bath it must be saturated with silver iodide. Saturation is only another word for instability; a slight change in temperature will upset the equilibrium, and pinholes and other troubles ensue.

Again, iodine in contact with ether forms organic compounds, possibly aldehyde, and acetic acid, reducing silver nitrate to a metallic state, the silver bath to a state of chaos, and the operator to profanity, and so far as I am personally concerned the method of Scott Archer and Hardwich is dead.

Now, instead of collodion, in which the principal ingredient is an iodide, a bromide is substituted; I say the principal ingredient because neither an iodide, nor a bromide, used alone will give a negative free from fog, and I wanted to entirely banish the use of silver iodide; I mix with the bromide a chloride. This formula has done good work.

Dissolve

Ammonium bromide	240 grs.
Calcium chloride	90 grs.
Industrial spirit	8 ozs.

When dissolved, filter, then add

Methylated ether, .725	12 ozs.

and add this to 60 ozs. of Johnson's or Penrose's plain collodion, and allow at least a fortnight to ripen.

Sensitise in 60 grs. of silver nitrate to each ounce of water. Silver bromide or chloride not being soluble in a solution of silver nitrate, no saturation is required.

Plates coated with this collodion and sensitised in the plain silver bath may be manipulated exactly as one of the old wet-collodion plates would be, *i.e.*, after exposure in the camera develop the image with an iron developer, and finish it off in the good old way; or wash out all the free silver nitrate, expose whilst still wet, then develop with hydroquinone or any other alkaline developer.

This method is extremely useful when long exposures are required such as making 250 step-and-repeat exposures upon a plate

36 ins. by 24 ins., avoiding any corroding of the edges of film caused by the presence of free silver nitrate.

Again, with this collodion, if the washed plates are coated with an organifier, such as any of the old well-known preservatives, gum gallic, gin, whisky, coffee or beer (although I have grave doubts about post-war stuff), and then dried, these plates can be made colour sensitive by using the dyes sent out by the Ilford Co.

Thus plates may be made capable of physical development, or alkaline development, colour blind or colour sensitive.

All the old bath troubles are banished and collodion is elevated into a certain and thoroughly practical process.

In reply to other questions Mr. Wilkinson said that if a collodion salted with a bromide only were used it was very seldom that a negative could be obtained free from fog. If, on the other hand, the iodide or chloride were mixed with it, an image quite free from fog was obtained. A very good proportion was four parts of bromide to one of chloride in the collodion. Colour sensitising could be done by bathing the plates in exactly the way recommended in the Ilford booklet for the bathing of gelatine plates.

If it was desired to make micro-photographs—that is to say, small photographs made from large—it was advisable to make a 5 per cent. solution of collodion and then pour it into water, wash it well with water, press it between clean cotton or linen and spread it out to dry. It would then give a very fine grain indeed. For these very tiny micro-photographs, however, there was nothing better than the old albumen process. It was slow, although with electric light one could get a good exposure in about 30 seconds. The collodion method was a much quicker process, and the resulting grain was nearly as fine.

The bromised collodion had just a little over double the speed of the ordinary iodised collodion, and it was also quicker as a dry plate. For alkaline development the sensitised plate was drained, soaked in two or more changes of clean water for about five minutes, rocking the dish occasionally, rinsed under the tap and drained. It might then be put into the dark-slide, the exposure being a little less than for an ordinary wet plate. In the dark-room it could then be developed with any of the alkaline developers. If it was desired to dry it before exposure, one flooded it with a preservative, stood it up to dry in the dark-room, and then treated it just as an ordinary dry plate. If a line subject, the development was with hydroquinone, but if a continuous tone subject, development could be with amidol or any other developer, just as in the case of a gelatine dry plate.

The old wet-collodion process is still the sheet anchor of process engravers, and during its reign of seventy years has undergone little alteration from the original formula of Scott Archer and of Professor Hardwich, and this in spite of the heart-breaking vagaries of the silver bath, which have had untold pages of literature devoted to them.

As long ago as the sixties of last century M. Carey Lea and Thomas Sutton tried to rouse enthusiasm for a collodion containing bromide, instead of a mixture of iodide and a bromide, but a collodion containing one salt (be it bromide or iodide) will not work, and photographers got the impression that a silver bromide film was not amenable to development by physical or acid solutions. Then Messrs. Bolton and Sayce introduced their collodion-emulsion process, a process that was successful right from the beginning. Consequently all progress with a method entailing the use of a silver bath was stopped, and when in course of time gelatine dry plates came into being wet collodion, with its many inconveniences was shelved entirely by the photographic world. When its second incarnation took place, with the inception of photo-engraving, the process men had too much to learn in regard to etching, screen negative making, etc., to bother about improving a process which was to them quite satisfactory, the bath troubles being got over by the sensible and business-like procedure of having plenty and to spare of silver bath, so that if one lot struck work another was ready to take its place.

Just before the war I came across one of Mr. Sutton's articles, and made up some collodion with cadmium bromide, another lot with ammonium bromide, and both lots were given a fortnight to ripen, but, try as I would, I could not get a clean negative, even with an 80-grain silver bath, and that very acid.

Calcium chloride was then mixed with the collodion and the first plate developed with an iron developer was quite a success. When the war came I switched off into ordinary portrait photography, and until 1920 was unable to make experiments of any kind. Since then I have given considerable time to studying and experimenting with bromised collodion, and can now safely say that, given an intelligent operator, without prejudice against new fangled ideas, the old wet collodion is quite dead.

Bromo-chlorised collodion procedure has many advantages. First of all the silver bath is just a solution of silver nitrate in water, 70 or 80 grains to the ounce. Just made acid with nitric acid it is at once ready for use, and no matter how the atmospheric temperature varies, the bath works uniformly and well, until at last the time of sensitising gets longer and development lags, occasioned by lack of silver nitrate. Then add with more silver nitrate, and everything is all right once again.

The bromo-chlorised film, after exposure in the camera, may have the image developed, fixed, copper-intensified, cut, and intensified exactly as is the practice in the old wet-collodion process. If the silver bath be kept up to strength the camera exposure is shorter and the density of dots, etc., greater.

When long exposures are needed, as in step-and-repeat machines, it is advisable to wash the sensitive plate in clean water until all free silver nitrate is got rid of. Then drain, and expose (no loss of sensitiveness need be feared), and develop with an alkaline developer. The image flashes out at once, and full density is attained in from 30 to 60 seconds, *wash* and fix in cyanide or hypo, again wash, flood with iodide of potassium and iodine and cut with cyanide, etc., as usual.

The washed sensitive plate may be converted into a dry plate by flooding with gum gallic preservative, drained and dried.

Thus with bromo-chlorised collodion it is possible to develop and finish the negative just in the old wet-collodion way, or wash out the free silver nitrate, expose wet, develop with an alkaline developer (say, hydroquinone for a line subject, pyro-soda for continuous tone), and then finish in the same way, or after washing away the silver nitrate apply a preservative, dry the plate, and you have a dry collodion. By these methods colour-blind plates would result, but by bathing in certain dyes, before applying the preservative, the dry plate can be made colour-sensitive.—W. T. WILKINSON.

The following patents have been applied for:—

APPARATUS.—No. 31,779. Apparatus for production of negatives for photo-mechanical processes. W. T. Wilkinson.

PRINTING PROCESSES.—No. 1,982. Photo-mechanical printing process. A. R. Trist.

PREVENTING BREAKING OF GLASS GRADUATES.—The breakage of glass graduates in the dim light of a dark-room by knocking them over is common enough, especially in places where earthenware sinks are used. I have found (writes a correspondent) that such breakages can be avoided if a fairly thick india-rubber band is placed about the top of the graduate. The softness of the rubber softens the fall of the measure, and I have never had a breakage since fitting a band, though tumbles have been many.

DECADENT PRESS PHOTOGRAPHY.—One of the reasons why Editors of modern picture newspapers are cutting down legitimate Press photographs (writes a correspondent) is because of the ridiculous poses in which many Pressmen picture athletes—notably performers in the football field. The game of football does not give the excellent opportunities for really good picture making that other sports do, but this is no excuse for submitting pictures which nobody can understand. Cricketers at the wicket usually make effective compositions, and are fairly easy to take, but a footballer is often an extremely difficult problem, because of the fast-travelling ball and its importance. A cricketer without a ball in the picture will be shown to be a cricketer because of his bat, leg-guards and—perhaps—stumps, but a footballer in a field without a football appears lost, and, maybe, meaningless to many—it depends upon one's knowledge of the game and the clothing worn. We are, however, to be treated to something new, for one of the evening papers recently started an excellent series of photographs of well-known football players in the field, with ball complete. The figures may be posed for the pictures, but if they are, they appear to be playing and full of action, while the all-important ball appears to be printed in, and in exactly the right place.

Exhibitions.

EDINBURGH PHOTOGRAPHIC SOCIETY EXHIBITION.

The Edinburgh Photographic Society's annual exhibition was opened on Saturday, February 18, by the Hon. Lord Salvesen, in the presence of a large gathering, in the Hall of the Society, 38, Castle Street, Edinburgh.

Lord Salvesen, in performing the opening ceremony of declaring the exhibition open, said that practically the rise and progress of photography were measured by the life-time of many people still alive. The art of photography during the last 60 or 70 years had increased in a most extraordinary way. During the war there was a new branch of photography that became possible, that of photography from the air, but that was not so remarkable as some of the other developments, such as X-ray photography and photography as applied to astronomy and other sciences. Photography was, of course, not an art which represented things exactly as they were. Although in a sense a photographic plate could not lie, still, in the hands of an expert it might produce very remarkable results. One had only to think of portrait photography in that connection; how beautiful a portrait might become with the proper lighting and the proper treatment of the plate after the picture had been taken. Landscape photography was a modern development as compared with portrait photography, especially as regards moving objects in the landscape. He hoped the exhibition would attract many people from the ranks of amateur photographers to join the Society, and take advantage of the facilities which the Society offered.

Photographers from all parts of the country have sent in specimens of their work, while members of the Society and local enthusiasts are also well represented. The standard of photography throughout the exhibition is excellent. The judges on this occasion have been somewhat sparing in their awards. The distinction of an award is, on that account, in view of the general excellence of the exhibition, of more than usual value, and it may be said that, in the main, those that have been singled out for special mention have clearly earned their distinction.

Section I. (Landscapes, Seascapes, and Kindred Subjects).—Medals are awarded to W. H. Reece (London) and W. Gerrett (Leven), the former for his picture "The Admiralty Arch," a picture notable for its fine tone and the natural liquescent appearance obtained by the play of light on the wet pavement, while several beautiful effects of light and shade are the characteristics in Mr. Gerrett's study. "Cramond Brig," a very fine study in nice grey tones by G. K. Ritchie, and a fine animal study of "A Young Lion," by J. C. McKechnie, both receive hon. mention.

Section II. (Portrait and Figure Studies).—The only medal award in this section is gained by R. Perkins (Clevedon) for "The Toiler," which contains a wealth of detail, and is marked by fine individuality. "Jackie," by C. Wormald (London), a child study, in which a soft expressive tone is obtained by contrast with a black background, receives hon. mention: as also do "The Fisherman's Wife," by the Rev. J. V. Haswell (Huddersfield); "Idle Moments," a study of three lads watching several yachts at sea, by H. W. Howe (Harrow); a "Portrait of Miss G. P.," by Miss A. M. Hunter (Edinburgh); and "Sharpening the Saw," by R. Douglas Croall (Edinburgh). Simplicity of subject accompanied by the contrast provided by dark shadows and soft high-lights give the last-named exhibit a particularly pleasing appearance.

Section III. (Lantern Slides).—Victor E. Morris (East Grinstead) received a medal for "Morning Mist in Lakeland," and hon. mention for two other slides, titled "In Winter Time" and "Bishop Readman's Tomb, Ely Cathedral."

FORTHCOMING EXHIBITIONS.

February 11 to 25.—Scottish Photographic Salon. Particulars from the Secretary, James F. Smellie, Braefindon, Allanshaw Street, Hamilton.

February 18 to March 4.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Latest date for entries, February 25. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 26.—Welsh Salon of Photography. Latest date for entries, March 9. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 16 to 18.—Leytonstone and Wanstead Camera Club. Latest date for entries, February 28. Particulars from the Secretary, Charles Wormald, 1, Colworth Road, Leytonstone, London, E.11.

March 27 to April 8.—Dennistoun Amateur Photographic Association. Latest date for entries, March 14. Particulars from the Exhibition Secretary, Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

March 28 to April 1.—Hackney Photographic Society. Latest date for entries, March 7. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 5 to 8.—Faversham Institute Photographic Society. Latest date for entries, March 31. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 6 to 11:—

Printing Frames.—No. 3476. Photographic printing frames. H. W. Harrington.

Developing Tank.—No. 4,113. Developing tank for film packs. G. P. Orde.

Micro-photography.—No. 3,682. Microscopes and devices for micro-photography. N. D. Chopra and E. H. Craggs.

Paper Films.—No. 3,596. Manufacture of paper films. J. Bautz and V. Kriegerbeck.

Cinematographs.—No. 3,595. Automatic cinematographs. J. Bautz and V. Kriegerbeck.

Cinematography.—No. 3,597. Cinematographic apparatus. J. Bautz and V. Kriegerbeck.

Cinematography.—No. 4,065. Films for cinematograph cameras, etc. A. W. Wyatt.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

MULTIPLE PRINTING FRAMES.—No. 173,116. (October 18, 1920). The invention is a printing apparatus for making one or any required number of photographic reproductions from one or more negatives in predetermined positions on the sensitive surface of zinc, aluminium or copper plates, stone or glass, to be afterwards printed by lithography, typography collotype or photogravure and for ensuring accurate registration in the reproduction of pictures or designs in two or more colours.

In order to enable the printing plate to be readily brought to any one of a number of predetermined positions on the sensitive surface, adjustable stops are provided for engaging the frames by which the printing plate is moved in the different directions.

A negative 2, fig. 1, previously mounted on a plate of glass of

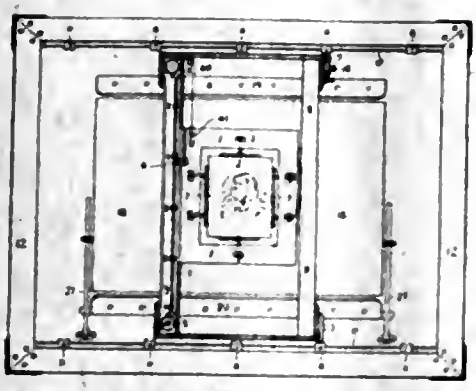

Fig. 1.

Fig. 4.

suitable size and thickness by means of Canada balsam, and having centre marks and cutting or marginal lines marked on its surface, is placed face downwards in the small frame 1 (fig. 1), the marks being adjusted to similar marks on the frame by means of the screws and plates 3. It is then clamped and held in position during the subsequent operations by these screws.

The stops 6 of the rod 7 let in the side of frame 8 are then adjusted to give the required positions for the pictures in the first row of reproductions, and the catch or stop 4 on the side of the frame 1 is drawn firmly against the first stop on the rod 7 by means of the cord 40 and pulleys 5, 5, rigidity of position being maintained by the triangular bearing rail 13, on which the frame 1 slides. The cord 40 working over the pulleys 5 has a small coil spring 41 on the end which joins the frame 1, thus

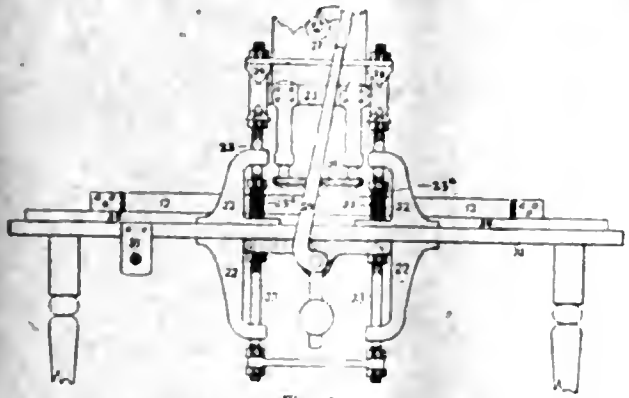

Fig. 2.

keeping the stop 4 on the frame 1 close up to the stop on rod 7, so long as the cord is kept taut.

The pressure plate 26 (figs. 2 and 3), which is a thick glass plate mounted in an iron frame, is then brought immediately over the negative by sliding the carriage 25 and light-box 27 along the triangular rails 24. The lever 29 (figs. 2 and 3) is then brought down to the stop 30, thus bringing the two cams 31 underneath the table, into action against the thick iron plate 32 of the stationary frame of the apparatus. By this means the whole structure of the rails and carriage is forced downwards bringing the pressure plate 26 into contact with the plate glass covering the negative with a pressure which can be modified

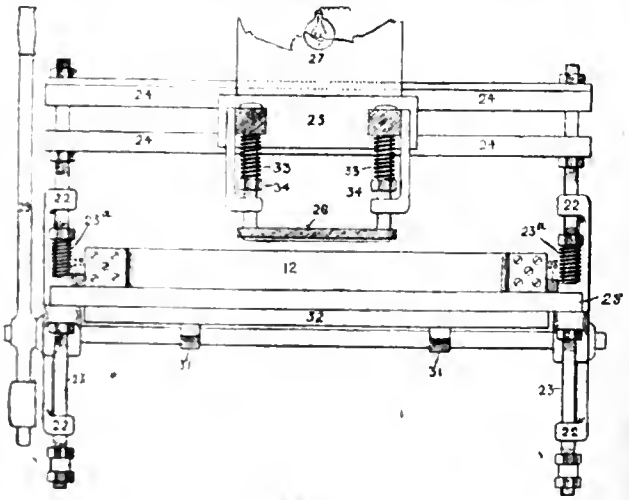

Fig. 3.

and adjusted by means of the springs 33 and nuts 34 on the bars carrying the pressure plate; during this movement the machine is kept rigid and free from all side-play by the bearings 22, so that the action is quite perpendicular and firm.

The pressure having been brought on the negative and contact assured with the sensitive surface 18 (fig. 1) the surrounding surface is shielded by means of curtains 35 (fig. 5), and the light 27, which may be an electric incandescent, or arc lamp or other suitable illuminant, is turned on for the requisite time and the first exposure is made. The light is then shut off, and the pressure released by raising the large lever 29 to the upright position, the carriage and rails and pressure plate being lifted off the negative by the strings 23^a on the guide rods 23.

The negative is brought into position for the next exposure by slightly turning the rod 7 (fig. 1). This brings a slot in the side of the stop 6 (fig. 1) opposite the catch 4 and enables the frame 1 to be drawn up to the next stop by the cord and pulley 5, when the operations of pressure and exposure are repeated.

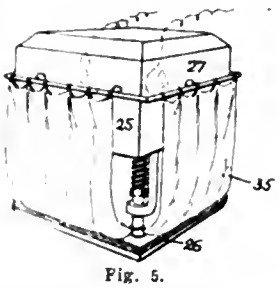

Fig. 5.

These combined operations are repeated until the first row of pictures is complete.

For the second and any subsequent rows, the stops 11 on the divided scales set in the sides of the large frame 12 (fig. 1) having been previously adjusted to the distance dividing the rows of pictures, the bolt 9 is released by unscrewing the milled head 10. This enables the two smaller frames 1 and 8 to be moved together to the next position for the second row, the whole arrangement being held firmly and exact by the V-shaped bolt 9 and the V-shaped slots in the stops 11. The whole arrangement of the three frames and the bed carrying the metal plate slides along the table between the runners 28 to enable each succeeding row of pictures to be brought immediately under the pressure plate 26 and light 27.

The drawings show the method of securing a lithographic machine plate 18 in position (fig. 4). The plate 18 with the usual registration marks (gripper and centre marks) on it, is clamped in position in the fixed clamp 19 and then,

by means of the clamp 20 and the levers 21 is drawn tight across the bed 36 and held firmly during the entire job. For lithographic stone the bed 36 is removed from the frame 37 and the stone simply placed in position, standing firm by its own weight; glass for collotype is clamped to a spare bed of requisite height to accommodate the thickness of the glass.—Albert Disteli, 17, Mount Pleasant Villas, Stroud Green, London, N., and Edward Francis Atkinson, 19, Romilly Road, Finsbury Park, London, N.

The following complete specifications are open to public inspection before acceptance :—

CINEMATOGRAPHY.—No. 174,931. Means for obtaining relief effects in motion pictures. E. Caslant.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

TINTONA.—No. 416,795. Photographic sensitised paper. The Leto Photo Materials Co. (1905), Ltd., 1, Crutched Friars, London, E.C.3, photographic manufacturers.

KALO.—No. 418,128. Chemical substances used in photography, photographic plates and photographic films. Ilford, Ltd., Britannia Works, Roden Street, Ilford, Essex, manufacturers of photographic plates, paper and films.

New Books.

A FRENCH MANUAL OF BROMOIL.—Under the title, "Le Procédé Bromoil," M. Charles Mendel has just published a booklet by M. G. du Marès dealing with the technique of the Bromoil process, of which, apparently, the author believes M. E. Coustet to be the inventor, M. Coustet having described the process in the "Photo-Gazette" of September, 1907. It would seem that M. Coustet and the late Welborne Piper were simultaneously at work upon the same problem. M. du Marès, who was an immediate worker of the Bromoil method, gives the formulæ for bleachers and a description of the methods of pigmenting which he has come to prefer. The booklet is issued price 1 fr. 20.

AIRBRUSH WORK.—From M. Charles Mendel, 118, Rue d'Assas, Paris, we have received a copy of a little manual of 48 pages (price 1 fr. 20), "La Retouche Photographique par le Pinceau à Air," by M. H. d'Osmond. Basing his text on the "Vaporigraphe" air-brush, the author describes the mechanism and method of using, and sets forth a course of self-instruction in the practice of air-brush working-up and colouring of prints and enlargements. The little manual contains a large number of reproductions illustrating the exercises which the beginner in airbrush work should set himself, following, in this respect, the excellent American manual on the subject by G. F. Stine, which was issued a little over a year ago by the publishers of "Abel's Weekly."

RESTORATION OF PRINTS.—A provisional report has recently been published by the Stationery Office for the Department of Scientific and Industrial Research on the cleaning and restoration of museum exhibits. It represents the results of experiments carried out by Dr. Alexander Scott, F.R.S., at the British Museum in the treatment of prints and engravings which had become spotted or stained with age, and also in the restoration of articles of metal and other materials. Acidified bleaching powder, well known as a remover of stain in paper, is recommended by Dr. Scott for this purpose. Drawings and other coloured pictures which contain white portions consisting of a lead compound may be restored by application of hydrogen peroxide applied by a special process, according to which solution of the peroxide is first absorbed by a block of plaster of Paris. Pyridine is recommended as a means for removing stains and disfigurations caused by oil or varnish. The report, which is quite a short one, is illustrated by a number of supplemental plates consisting of photographic reproductions of originals before and after restoration. It is supplied as Bulletin No. 5 by the Stationery Office, Imperial House, Kingsway, W.C.2, price 2s.

KALLITYPE PROCESSES.—No. 185 of the "Photo-Miniature," which has just been issued, is a monograph on the Kallitype iron-printing process and similar methods by Mr. James Thomson, an American worker, who has made the technique of these processes peculiarly his own, and has published many papers in the periodical press giving the results of his original experiments. Photographers with a taste for preparing their own sensitive material for the making of prints will here find direct and most practical instruction in compounding and coating the Kallitype sensitisers and in the handling of the prints, including a number of methods for modifying the colour obtained by direct development. It is hardly necessary to say that Mr. Thomson is fully versed in the process, and his directions, we are quite sure, can be strictly followed. We notice only one minor slip in the references to Kallitype. On page 218 the use of silver in the developer is described as a variation from the original Kallitype method of Dr. Nicol. In point of fact, Dr. Nicol's paper, when first put upon the market, contained only the iron salts, the developer consisting of silver nitrate in combination with such salts as citrates and borax. This method, however, was very quickly abandoned in favour of the practice of uniting the silver and ferric salt in the coating on the paper. Mr. Thomson also gives ample instructions and formulæ for the working of other iron-printing processes, and publishes a new formula for a sensitiser, compounded of ferric and platinum salts yielding prints of warm brown tone by direct development in a solution composed of citric and oxalic acids and silver nitrate. The monograph, in short, is a valuable compendium of these iron-printing methods, which brings the long experience of the author into exceedingly compact form. Messrs. Houghtons, Ltd., supply the "Photo-Miniature" in this country price 1s. 8d. post free; in the United States the publishers are Messrs. Tennant & Ward, 103, Park Avenue, New York, who issue it price 40 cents.

New Apparatus.

The Swift-Wheeler Photo-Micrographic Attachment. Made by James Swift and Son, Ltd., 81, Tottenham Court Road, London, W.1.

THIS very simple piece of apparatus provides the means of doing photo-micrographic work with an ordinary camera, and without any alteration of the latter beyond providing a flange to fit the screw of the collar fitted to the attachment. As shown in the drawing it consists of a microscope tube of the standard 160 mm. length, and carrying at one end an ordinary microscopic objective and at the other a Huyghenian ocular of the customary pattern. The object is held in a stage which is mounted on a sleeve sliding over the microscope tube, the stage being provided with a recess to admit

the ordinary 3 × 1 inch microscope slide which is held in position by spring clips. Thus it will be seen that the screwed collar *a* has simply to be inserted into the flange fixed to the lens panel of the camera in order to make the outfit ready for use. Coarse focussing is done by sliding the stage sleeve on the microscope tube, the mechanical workmanship of the pair being so excellent that really quite fine focussing may be done by means of it after a little experience. At the same time the ordinary focussing movement of the camera may be employed for obtaining final sharpness.

As supplied at the price of £5 5s. the attachment is fitted with a 1-inch objective and No. II. ocular of 6 magnifications. With this combination a camera extension of 10 inches permits a magnification of 40 diameters; an extension of 20 inches, one of 80 diameters. The use of a camera of longer extension (one of the old pattern field cameras which can often be bought for a small sum is excellent for the purpose) or of an extension tube allows of still greater magnification. On the other hand the embryo photo-micrographer may provide himself with oculars of higher magnification and can also employ objectives of shorter focal length. The combination fitted in the standard instrument will, however, bring within his range a wide field of photo-micrographic work. We allude in an article on another page to the attractions which such an outfit as this present to those anxious to make a beginning in photo-micrography at small expense and under conditions in which they require to learn little of the technique of using a microscope. Captain Wheeler, while frankly disclaiming great expertness in photo-micrographic work, has kindly shown us a number of photo-micrographs of excellent definition taken with this little attachment of his design. He is to be congratulated on the mechanical perfection with which Messrs. Swift have carried out his idea.

The Graber Eclipse Automatic Rotary Drying Machine. Made by Ellis Graber, 16, Newton Road, Tunbridge Wells.

Mr. Graber, whose machines for the automatic printing, developing, fixing and washing of continuous lengths of photographic development paper deservedly enjoy a very high reputation, has done well to add a further one for the rapid drying of the otherwise

completed bands of prints. The Eclipse machine, which has just been completed for this purpose, follows quite original lines which, so we judge, must make it highly efficient in use. The drying is done by means of heat communicated to the roll by electrically heated rollers in conjunction with a stream of cold air, and is further supplemented by fans which extract the moisture laden air. All these means are operated by the single power unit which drives the machine. The heated rollers are carried on a skeleton drum, each roller, as also the drum itself, being rotated. A further feature of the mechanism is that the heated rollers are allowed a period of rest from contact with the wet paper or card which is being dried, thereby giving each of the twelve rollers a chance to recover its temperature before again coming in contact with the moist paper entering the machine. Moreover, while the paper band passes through the machine at the normal rate of its travel through the developing and washing solutions, the drying machine itself runs at a greater rate, so that a high drying efficiency is obtained within a comparatively small space.

As shown in the photograph, the machine occupies a relatively small floor space, and is designed without the use of any blanket or web for the mechanical absorption of moisture. The coated side of the band of paper, in fact, does not come in contact with anything during its passage through the machine, and hence the latter is applicable to the drying not only of gelatine emulsion papers, but also of varnished or gummed papers, and those coated with an emulsion or sensitised with preparations of the kind used in manufacturing, for example, the iron-printing papers.

There is no doubt that producers of photographs in large numbers in the postcard and allied trades and also manufacturers of sensitive materials will be interested in examining the construction of this new appliance. An opportunity of doing so presents itself during next week, as Mr Graber is including one of the machines in his exhibit at Stand L 12, at the British Industries Fair, opening at the White City, Shepherds Bush, on Monday next, February 27.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, FEBRUARY 27.

Birmingham Phot. Art Club. "The Paget Colour Plate and How It Works." Demonstration. W. F. Carter.
Bradford Phot. Soc. "Amateur Photographer" Prize Slides.
City of London and Cripplegate P.S. "A May Holiday at Lake Geneva." W. Sanderson.
Dewsbury P.S. "Home Photography." A. Dordan Pyke.
Kidderminster P.S. "Passe-Partout Mounting." J. Armytage Batley.
Leeds Camera Club. Lecturette Competition.
Southampton C.C. "The Bromoil Process." C. M. Cooper.
South London P.S. "Mont St. Michel—the Abbey of the Archangel and its Seagirt Town." H. W. Fincham.
Wallasey Amateur P.S. Annual General Meeting.
Walthamstow P.S. "Toning Prints." E. Willcocks.

TUESDAY, FEBRUARY 28.

R.P.S. "Present-Day Portraiture." Thomas Bell, F.R.P.S.
Bournemouth C.C. "Sir Walter Raleigh." F. W. Ibbett, M.A.
Exeter P.C. "Æsthetics of Pictorial Photography." A. W. Walburn.
Hackney P.S. "Enlarging." W. H. Clark.
Leeds Photographic Society. "Assisi." H. S. Chorley.
Morley Photographic Society. Leto Demonstration.
Nottingham Phot. Soc. "Portraiture." Mr. Mills.
Nelson Phot. Soc. "Colour Photography." E. S. Maynard.
Rotherham P.S. "Through the Grecian Archipelago with a Reflex." Messrs. Butcher and Sons.
South Glasgow Camera Club. Lecture. W. S. Denver.
South Shields P.S. "Composition." J. W. Addison.
Stalybridge P.S. Lancashire and Cheshire Photographic Union Slides.
Tynemouth Phot. Soc. "Through the Ægean with a Reflex." W. Butcher and Sons.
Welfare Camera Club. Open Night.

WEDNESDAY, MARCH 1.

Accrington Camera Club. "Bromoil." J. B. Potts.
Catford Camera Club. Members' Queries and Criticisms.
Croydon C.C. "A New Assortment of Travellers' Samples." F. Ackroyd.
Dennistoun Amat. Phot. Soc. Annual General Meeting.
Forest Hill and Sydenham P.S. "Pictorial Composition." H. Sadler.
Halifax Scientific Society. "Folk-lore of Bird and Beast." H. Walker.
Ilford P.S. "Sepia and Platinotype." Rev. J. H. Mitchell.

Leicester Phot. Soc. "Making Lantern Slides." Mr. Croydon. "Mounting the Print." H. Lee Hopkins.
Partick C.C. "Panchromatic Plates and their Uses." John Doig.
Tunbridge Wells Amat. Phot. Assoc. Members' "Colour" Slides.

THURSDAY, MARCH 2.

Camera Club. "Laying of Submarine Telegraph Cables." E. Bevan Bothwell.
Gateshead C.C. Scottish Portfolio.
Hammersmith Hampshire House P.S. "Sicily, the Garden of the Mediterranean, and Scenes in Old Pompeii." Chas. H. E. West.
Letchworth C.C. "Still Life Photography." D. W. Brunt.
Liverpool Amat. Phot. Assoc. "Wonderlands of the Western World." J. Dudley Johnston.
North Middlesex Phot. Soc. Competitions—Prints and Slides. Members' Queries.
Rochdale Amat. Phot. Soc. "Architecture." H. B. Carpenter.
Wimbledon C.C. "More Gems of Architecture." E. R. Bull.

FRIDAY, MARCH 3.

Wombwell Photographic Society. Beginners' Night.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 21, the president, Dr. G. H. Rodman, in the chair.

The President announced the gift to the Society by the Kodak Co. of a studio camera, together with full equipment for the development, etc., of Eastman portrait film. He had equal pleasure in announcing that Messrs. Taylor, Taylor & Hobson had presented for use with the camera one of their large aperture lenses of 13 in. focal length. The meeting signified its thanks to these donors by hearty applause.

Mr. G. A. Booth, F.Z.S., delivered a lantern-lecture entitled "Natural History Photography." He dwelt upon the cultivation of the gifts of patience and observation which a study of the wild life of the fields and woods—or even of the suburban garden—promoted, and urged that such study should replace that of some of the abstruse subjects in the curriculum of schools. He depreciated the rivalry in the collection of natural specimens; Nature photography was more useful, and did not involve the extinction of rare species.

He then proceeded to show a large number of lantern slides from his own collection of negatives of British birds, very many of them of remarkably high technical quality. His work had been done with lenses of from 9 to 13 in. focal length, and with a reflex camera, the latter a type which he considered absolutely essential for Nature photography.

On the proposition of the Chairman a most hearty vote of thanks was accorded to the lecturer.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square on February 10. Present:—Messrs. M. Adams, A. Basil, G. Bennett, G. Chase, T. Chidley, A. Corbett, A. H. L. Chapman, C. F. Dickinson, A. Ellis, W. E. Gray, G. Hana, R. Haines, H. C. Spink, H. A. St. George, R. N. Speaight, A. Swan Watson (President), T. C Turner, F. Wakefield and W. Wedlake, with the Secretary (Mr. Lang Sims). Mr. Alfred Ellis in the chair.

Mr. Speaight (Hon. Treasurer) submitted details of the income and expenditure for the past year. After a lengthy discussion the balance-sheet was approved and passed.

The Secretary read the draft of the annual report which he had prepared.

It had been suggested that a covering letter should be sent with the report, giving an explanation in regard to incorporation, and asking members to fill the form, which should also be enclosed.

The Chairman thought that a small copy of the memorandum of the articles of association might be sent. Every member was entitled to a copy, otherwise at the annual general meeting, to be held March 10, the whole document would have to be read through. It was agreed to send a copy.

Mr. Swan Watson said that it was necessary, particularly from the point of view of Scotland, that the P.P.A. "Circular" should be re-started very soon. Members far from London often expressed the opinion that they paid 10s. and got nothing for it. The "Circular" should be something exclusive, and not a mere copy of what appeared in the photographic Press. Members of the Council, perhaps, might write special articles. It was also essential to have a printed list of members.

It was agreed that the matter, with letters which had been received from Mr. Read and Mr. Lambert, should be referred to the Propaganda Committee.

After Mr. Adams and Mr. Turner had spoken as to the urgency of starting a journal, Mr. Swan Watson formally proposed that the "Circular" should be re-started, and that the Propaganda Committee be asked to draw up a definite scheme. The proposition was seconded and carried.

The Council further agreed that a list of members should be published in the first of the new series of the "Circular."

Mr. Speaight said he hoped the various Congress sub-committees would arrange early meetings. The Secretary might be asked to send to the secretaries of these sub-committees the names of the members of each, and a general meeting of the Congress Committee might be called previous to the next Council meeting.

The names of the Councillors serving upon the various Congress Committees were given as follows:—

Finance.—Mr. Speaight, Mr. St. George.

Exhibition, Trade Section.—Mr. Bennett, Mr. Chase, Mr. Corbett, Mr. Wakefield.

Exhibition—Picture—Home.—Mr. Marcus Adams, Mr. Basil, Mr. Corbett, Mr. Speaight, Mr. St. George, Mr. Wakefield.

Exhibition—Picture—Colonial and Foreign.—Mr. Marcus Adams.

Propaganda and Catalogue.—Mr. Barratt, Mr. Bennett, Mr. Haines, Mr. Hana, Mr. Wakefield.

Entertainment and Music.—Mr. Chase, Mr. Ellis, Mr. Gray, Mr. Chidley, Mr. Lambert, Mr. Bertram Park.

Lectures and Demonstrations.—Mr. Haines.

Assistants' Meetings.—Mr. Marcus Adams, Mr. Basil, Mr. Chase, Mr. Hana, Mr. Speaight, Mr. Wedlake.

Lantern, Special Lighting.—Mr. Chaplin, Mr. Dickinson.

The Secretary read a letter asking for information as to the terms arranged with the Westminster Electric Light Corporation, Ltd., and Mr. Corbett said that the correspondent should be reminded that the Electricity Commissioners were the governing body for the City, and had decided that the rate should be uniform all over London. All the stations would eventually be under one control, but not perhaps for about six years. No particular charge could be enforced on the company.

Commercial & Legal Intelligence.

LEGAL NOTICES.—At an extraordinary general meeting of the members of the Photo Productions, Ltd., held at 1, Eton Terrace, Richmond, Surrey, a resolution was passed to the effect that the company be wound up, and that Mr. C. O. Bartley, of the above address, be appointed liquidator.

NEW COMPANIES.

TEDD CAMERA CO. (LONDON), LTD.—This private company was registered on February 13 with a capital of £1,500 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in photographic cameras of all kinds. The subscribers (each with one share) are: H. D. Richardson, 2, Broad Street Place, E.C., merchant, and D. J. Neame, 10, Throgmorton Avenue, E.C.2, stockbroker. The first directors are not named. Registered office: 2, Broad Street Place, E.C.

THE LATE MR. C. ESSENHIGH CORKE.—We are very sorry to see the announcement of the death, on February 21, of Mr. Charles Essenhigh Corke, of Sevenoaks, in his seventieth year. Mr. Corke had for many years followed the professions of an artist and a photographer, his interests in the latter direction having been very successfully embodied in the Sevenoaks studio conducted first by his son, who died a few years ago, and until the present time by his daughter, Miss Beatrice Essenhigh Corke.

MR. J. M. SELLORS, hon. secretary of the Croydon Camera Club, asks us to point out that his address is 50, Russell Hill, Purley, not 78, Parchmore Road, Thornton Heath, as stated in the latest edition of the Red Book. The latter is the address of the president of the Club, and the result of the error is that communications for Mr. Sellors are constantly delayed. It is not known what the formidable Mr. Sellors is doing to the editor of the Red Book. At any rate those having the occasion to communicate with him will be well advised to take notice of the present intimation.

News and Notes.

ROYAL INSTITUTION.—On Saturday, March 4, Sir Ernest Rutherford begins a course of six lectures on Radio-activity.

POLICE OFFICER'S HOBBY.—The enlargement of criminals' photographs to hang in his study was the hobby of Superintendent Dibben, who has died at Newport Pagnell, Bucks.

COPYRIGHT IN BULGARIA.—In consequence of the accession of Bulgaria to the revised Berne Copyright Convention of 1908, an Order in Council was made on February 6, 1922, under Section 29 of the Copyright Act, 1911, extending the provisions of the Act to Bulgarian authors and works. A copy of the Order may be seen in the Patent Office Library, 25 Southampton Buildings, London, W.C.2.

UNITED STEREOSCOPIC SOCIETY.—This well-known society now has vacancies for three or four new members. It is a postal one, and circulates folios of slides monthly, to which every member contributes one each time it comes round. An annual competition is held for the Walshe Owen silver challenge trophy, and lantern lectures are given monthly during the winter session at headquarters. The subscription is 5s per annum. Particulars from the secretary, Mr. A. T. Mole, 39, Westbere Road, West Hampstead, London, N.W.2.

REVUE D'OPTIQUE.—We have received the first issue of the new French optical journal, "Revue d'Optique, Theorique et Instrumentale," recently mentioned by M. L. P. Clerc, which is being published at 140, Boulevard du Montparnasse, Paris XIV., price 2 fr. 50 per issue. The first number contains a paper by MM. Ch. Fabry and H. Buisson on the Jobin photometer without diffusing screen. There are reviews of new optical instruments, one of which is the elegant Homeos stereoscopic camera of Jules Richard, and of recent books. In subsequent issues it is intended to publish a list of notable articles on optical subjects appearing in the periodical press during the preceding month.

PHOTOGRAPHISCHE KORRESPONDENZ. Owing to the economic conditions prevailing in Austria the Photographic Society of Vienna has been compelled to discontinue for the present year the publication of the monthly "Photographische Korrespondenz," the journal which, since its establishment in 1863, has contained a large proportion of the most important Continental communications in the scientific and technical branches of photography. As a substitute for the twelve monthly issues of the present year a "Festschrift" will be issued, consisting of articles and illustrations. The price of this issue for countries other than Austria and Germany has been fixed at five Swiss francs, or their equivalent.

CONCERNING PRESS PHOTOGRAPHY. The following paragraph is taken from the current issue of "The Journalist," the official organ of the National Union of Journalists.—The time has come for Press photographers to close their ranks. It may be necessary to call those to our aid to whom we are affiliated, and who are already cognisant of the extent to which we are exploited. Hordes of young dads swarm into Fleet Street offering themselves at very low salaries; their knowledge of even elementary photography is a negligible quality. Etiquette and education are not part of their equipment. Perhaps a work-shy photographer with a couple of rooms equipped to turn out photographs for Press work will take them on at fifty-fifty, with instructions to follow the trained man about and do what he does. With three such men, each averaging, say, two publications per day in London alone, this would make a comfortable little income for the work-shy man, who can sit by the fire, smoke his pipe, read through the papers for more stunts for his drudges to cover, meanwhile bringing disrepute on the heads of *bona-fide* Press photographers by their crude behaviour. A few of these men may by chance drift on to an agency at a very low salary, and as long as they turn over up to, say, £80 per month, all is well. They usually cover simple jobs and learn their profession during the meantime at the expense of the competent Press photographer. The fully-trained man is expected to show a turnover from £120 per month. He is expected to keep a swarm of dead heads plus rent, light, power, and then, on the top of all this, a substantial profit for the proprietor. It has been admitted that two good men are the mainstay of an agency. One such man sometimes gets a picture which is published in papers all over the world in papers which he never sees. They are kept out of his way; he might ask for more money. Well, here is what is happening: Two men start in the picture business, one man gets all the dud photographers, who always bring home dud pictures, the other has all the good photographers, who, in eight cases out of ten, bring home the best pictures. The business of the man who employs the good men gradually grows. The proprietor then casts round to see how he can make a bit more. He recalls that he has had a number of applications for jobs from the men whose business is not flourishing; why not take a few of them on and get rid of a few of the better paid men? The firm is made now; he can afford to do so. The top minimum for photographers is £8 8s. Put the good man on a basis of 60—40—that is, 60 per cent, for the man and 40 per cent. for the proprietor. Who would be better off—the man or the agency? Photographers can think it out!

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

PRICES OF PHOTOGRAPHIC MATERIALS.

To the Editors.

Gentlemen,—I am glad to see this matter has been taken up by someone at last.

As a professional photographer I, too, think that we have stood the high prices too long, and beg to put forward a strong protest. After leaving the Service at the conclusion of the war, one naturally expected to have a reasonable chance of resettling to one's business; instead of which it has been a continued source of worry and thought how to cope with the ever-increasing costs. Surely now is the time to expect a reduction of the very high prices now prevailing.

I certainly advise restricted purchases of material until something is done by the manufacturers to help us. Customers are continually asking to have the prices reduced, as in other businesses, but can we safely do so at present?—Yours faithfully,

W. HAIG PARRY.

148, Lunthorpe Road, Middlesbrough.

INVENTIONS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—Permit me to point out that in the mass of citations by Mr. Wall (page 27), there cannot be found a single anticipation of my addition of a non-actinic soluble dye to an unpigmented bichromated colloid film as one step in the production of tenuous relief prints subsequently coloured by dyeing. My patent claim 3 reads: "Incorporating a non-actinic water soluble dye in the sensitised colloid coating, exposing said sensitive coating to light, developing the print, discharging the dye, and then subjecting the print to its appropriate dye bath."

It cannot be true that anyone who did not do what I specified and limited my claim to in my patent anticipated that patent. Patents are constantly being upheld in the law courts on the basis of such [illegible] as Mr. Wall ignores, when he says that Ducos du Hauron, MM. Lumière and Pfenninger anticipated my patent. Others *have* used dyed unpigmented bichromate sensitised films in the process of producing dye-coloured relief prints, but only after the date of my patent. My patent on the use of a dyed gelatine silver bromide [illegible] as one step in the production of a tenuous gelatine relief print through the agency of a developed silver image was not [illegible] and was similarly limited, but its validity was recognised by [illegible] large "interests" who would otherwise have exploited [illegible] themselves, and who actually made tentative advances [illegible] acquiring the patent rights.

Mr. Wall [illegible] and obscures the issue. Barring an occasional [illegible] work he is doing in collating historical [illegible] and admirable. While our point of

view and our opinions are not always the same, I believe we are equally sincere in wishing to establish the truth.

The number of my U.S. camera patent to which Mr. Wall refers has now twice been printed wrong. It is 531,040. It is not entirely true, as asserted by Mr. Wall, that this patent is the same as English patent 2,305, '95, because claims which I was entitled to and obtained in the U/S. Patent Office, I was told were barred in England by disclosures at a public demonstration which I gave in London before the British application was filed, and which I therefore omitted. Obviously, my claim to the original invention of a specific type of camera is not discredited by the fact that some years after someone made one with one of the mirrors at a different angle. Mr. White did not alter the type or make an improvement, and the camera which he did make was subject to claims granted to me in my U.S. patent.—Very truly yours,

F. E. IVES.

1,327, Spruce Street, Philadelphia, January 4.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. C.—The addresses you ask for are:—Messrs. Gowans & Gray, 5, Robert Street, Adelphi, London, W.C.2 Messrs. T. C. & E. C. Jack, 35, Paternoster Row, London, E.C.4.

T. C.—(1) Three negatives are taken in succession on a single plate through a ruled screen, which is shifted between each exposure. (2) Apparatus and materials from Move-e-graphs, Ltd., 56-58, Eagle Street, Southampton Row, London, W.C.1.

F. C.—Zinc has not a very long life as a metal for developing solutions, and still shorter for acid fixing solutions. It should not be used for these latter at all. Copper will last very much longer, but the best tank for either is hard wood, either with well-made joints or a hard wood frame with a lead lining.

E. J.—Your space is rather cramped, but you should get good results with three half-watt lamps, one 2,000 c.p.and two 1,000 c.p., placing the 2,000 as main light about 6 ft. from the background and about 3 or 4 ft. to one side of the centre of background; one 1,000 as a side light and one as front high light about centre of background 6 ft. away.

J. S.—Write to Messrs. Pictorial Machinery, Ltd., 7, Farringdon Road, London, E.C.1, for particulars of their transfer bromide paper, which would allow you to make negatives of the character you require very cheaply and easily by means of a multiple back camera such as you can get from Messrs. Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2.

B. H.—(2) No certain method of giving H. & D. or Watkins numbers equivalent to degrees Warnerke. We should say that what was formerly rated as 25 Warnerke is equal to about 100 H. & D. at the present time. (3) So far as we know there is no agent here, but try Messrs. J. F. Shew & Co., 21, Bartlett's Buildings, Holborn Circus, London, E.C.1, who were previously the agents.

F. H.—The usual caulking used for wooden tanks is a stiff mixture of red lead and linseed oil; or the joints may be given a good coating of bitumen paint before being fitted together. Many tanks are sufficiently well made to render any caulking unnecessary, and the presence of a material which in the course of time is liable to perish to some extent is certainly a possible cause of leakage.

E. M.—(1) A condenser could easily be polished for the removal of scratches unless these are very bad indeed. Write to the Premier Optical Co., 63, Bolton Road, Stratford, London, E.15. (2) Do not stint it for size; we should say, roughly, that it should be at least 24 in. × 24 in. high and wide, and not less than about 18 in. deep. (3) Twelve inches is a very good focal length for large cabinet heads.

F. N.—We are afraid that the position you describe is not at all suitable for the erection of a studio. The glass at the end would only tend to flatten the lighting, and the width is too little for the top light to be controlled effectively. If you thought it worth while, you might put in two 1,000-c.p. half-watt lamps to serve as a side light, but if it is to be used only for amateur work, we should recommend you to use an ordinary room where you will have much more manageable light.

F. A.—There is no necessity for a copyright photograph to be marked "copyright." If you took the photograph of the stone laying on your own initiative, that is to say without receiving the order from anybody to whom you would look for payment, the copyright is absolutely yours. The only circumstances in which the other photographer would be entitled to make the copies are that he received the order to do so from the person who, in the first instance, gave *you* an order to take the photograph. But we infer from your letter that no such person exists.

W. H.—Eight 1,000 lamps will be ample, probably six will be sufficient. These should be arranged in a curve, or L shape if more convenient. Use *thin* white nainsook or madapolam for diffusing screens and white reflectors. The hemispherical reflectors, sold by the General Electric Co., are excellent, but are rather costly. By all means arrange to have the lamps to raise and lower, as this greatly shortens the exposure with sitting figures and children, besides giving more control of the lighting. No. 7 may be used instead of a reflector it gives rather better modelling. It is a good plan to fix the lamps under the solid side of the roof, so as to avoid interference with daylight working.

H. P.—The name Heliotype is usually applied to a modification of the collotype process, invented by Ernest Edwards many years ago. A waxed glass plate is given a substratum of bichromated gelatine containing a little chrome alum, and this film, after drying, is stripped off and the surface, which previously had been next to the glass, exposed under a reversed negative in the usual way. The other side of the exposed film is hardened by exposure to light, and is mounted on a metal plate coated with india rubber. The bichromate is then washed out and the plate is ready for printing. You can get photo-litho paper from Messrs. Penrose & Co., 109, Farringdon Road, London, E.C.1, but so far as we know only in one surface.

F. N.—(1) For all-round work a lens of from 8 to 10 inches focal length will be quite suitable; for reduction to lantern size one of about 5 inches will be best. Much depends upon the bellows extension of your enlarger. You would require at least 15 inches draw to make a lantern slide from a half-plate with a 5-inch lens. (2) It is a matter of taste as to which way to place a half-watt lamp in the lantern. Some prefer to turn what is normally the bottom towards the condenser, but we prefer to hang the lamp in the usual position, and to tilt it slightly so that the whole of the filament is effective. In either case you will have to place a piece of finely-ground glass as close to the lamp as possible to secure even illumination. About 200 c.p. is sufficient.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3226. Vol. LXIX. FRIDAY, MARCH 3, 1922. Price Fourpence.

Contents.

SUMMARY.

A scale or calculator for ascertaining the time of development by making appropriate allowance for the temperature of the developer and the development speed of the plate when using a pyro-soda developer is the invention of an American worker. (P. 123.)

In a leading article we deal with the copyright question concerning the making of photographs bearing a close resemblance to others made previously (P. 122.)

Further experiments in hypo-alum toning have been carried out by "Thermit," who gives a most practical method of accelerating the process of toning bromide prints. (P. 126.)

A multi-printing frame for use in producing multiple designs, images, etc., on plates and stones in one or more colours is the subject of a patent. (P. 127.)

A temporary arrangement for holding lenses in position on a camera front during testing is described on page 121.

The usefulness of a motor-cycle to photographers is described by a correspondent, who gives some helpful details. (P. 125.)

Special attention is called to the advantages of a permanganate-sulphuric reducer, a very much neglected but most useful solution. (P. 121.)

A simple method of testing whether a fixing bath for prints is working at active strength will be found on page 122.

The eighth of an unbroken series, the British Industries Fair opened at the White City, London, W., last Monday. Cinematography is well represented. (P. 131.)

Lecturing at the Camera Club, Mr. Arthur Banfield declared that, if properly used and not abused, the Bromoil process is one of the most beautiful which photographic science has given us. His method of working is fully described on page 130.

The paste-on method of making combination prints was very strongly advocated at the Croydon Camera Club, and several excellent specimens in support of the method were shown. (P. 129.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT

Facts and fallacies in colour photography are dealt with in an article by Lt. Com. H. E. Rendall, who gives an instructive criticism of one-exposure cameras for the making of the three images. (P. 9.)

A French-Italian system of colour cinematography is described on page 10. A method of optical printing of side-by-side positives from negatives taken alternately through green and orange filters is adopted.

Mr. F. J. Stoakley dealt fully with the progress of colour photography before the Camera Club last week, showing a remarkable series of examples of both current and obsolete processes. (P. 12.)

EX CATHEDRA.

A Simple Lens Holder. It is sometimes necessary to make a temporary arrangement for holding a lens upon the camera front for testing purposes. It must be strong enough to preclude the possibility of accident and rigid enough to keep the lens-axis normal to the plate, while it should not necessitate much work in setting up. The universal iris adapters which were at one time common were excellent, but, we believe, are no longer on the market, while their cost was rather too high if they were not often required. A simple and perfectly effective device consists of a stout card large enough to cover the hole in the lens panel. In this card is cut a hole into which the screw-thread of the lens mount fits fairly well, the lens fitted in and the flange screwed firmly on the inner side of the card. The whole is secured to the front by four or more good push pins. In the case of cameras with very small fronts the card may be cut to fit into the recess, the panel being dispensed with. Spare panels for permanent use may be made of very thin three-ply wood; the latter is better than cigar-box wood, which is very liable to split. The opening may be cut with a fretsaw or even with a penknife, and rebates, if needed, are better made with a file than with a knife or plane. A coat of varnish stain will make such a panel quite presentable.

* * *

A Neglected Reducer. Many photographers are not fully aware of the advantages offered by the permanganate sulphuric acid reducer. It is cheap, its action is certain, safe, and easily controlled, and the solution keeps fairly well. A formula may be found in the current issue of the "Almanac," or the reversing solution employed for the Autochrome plate may be used, diluted to about double its normal strength. The reducer should not be employed until after a negative has been well freed from hypo, and should not be used for a dry negative, the latter being soaked for ten minutes, unless the greatest degree of reduction is required in the high-lights. If it is needed to reduce harsh high-lights in a portrait negative or windows in an interior, the negative should be dry and put straight into the reducer, which will then attack the high-lights before the shadows, and by the time the action has started upon the latter, the reduction on the high-lights will probably have gone far enough. The action of the reducer is rapid, and it should be diluted if only slight reduction is needed, and the progress watched carefully. If a very great reduction of contrast is required the dry negative may be treated, washed and dried, and then, when dry, a second application of the reducer may be given. Care is needed when doing this, and it should only be contemplated in extreme cases. The solution should not be used after being kept a long time, when it becomes cloudy; it then tends to act unevenly or produce brown stains upon the negative. If these

occur they may be removed with a 10 per cent. solution of sulphite of soda, to which 2 per cent. of oxalic acid has been added.

* * *

A Test for Fixing. We do not think that we are very far from the truth in saying that the fixing bath is among the things generally neglected by the average photographer who, so long as he gets no trouble from so doing, is inclined to make up the stock solution haphazard, without weighing, and in all probability uses the bath long after its action as a fixer is considerably lessened. Many a case of blisters, frilling, etc., can be traced to the use of too strong a fixing bath, particularly with some of the modern emulsions which are so finely adjusted that to depart very far from the makers' instructions and formulæ is to invite trouble. Some time ago we were consulted as to why a certain batch of prints blistered, whereas others upon another make of paper at the same time and in the same bath exhibited no signs of the defect. Subsequently, it was shown that the fixing bath was actually twice as strong as recommended by the maker of that particular paper. Though hypo is cheap, many photographers are inclined to overwork their fixing baths, as a simple test will show. If a piece of bromide paper is taken and placed in a sulphide solution as used for sepia toning, it will be found to turn rapidly to a dark-brown colour. If it had been previously fixed and washed the sulphide would have had no effect upon it. Thus it will be seen that the worker has to his hand not only a means of testing whether a particular bath is still working at active strength, but by immersing a piece of bromide paper in strips, for various times, he will also gain an idea of the time needed for the fixing bath to perform its function with any particular brand of paper.

SIMILAR SUBJECTS OF PHOTOGRAPHS IN RELATION TO COPYRIGHT AND CONTRACT.

Among the questions relating to copyright, which present difficulties by reason of the somewhat obscure meaning of the law in regard to them, are those which are concerned with photographs which exhibit a close degree of similarity in consequence of very similar subjects having been photographed. Such questions are not simply the product of an imagination fertile in discovering imperfections in the Act, but frequently arise in everyday commercial transactions. Enquiries which turn upon this question frequently reach us, and are difficult to answer, except at a length and with a knowledge of the exact circumstances which are not always at disposal. It may, therefore, be of advantage if we endeavour to set forth with as much precision as is possible the considerations from which an individual photographer can draw conclusions for his guidance.

A fairly typical case of the problem is somewhat as follows:—A photographer is asked to make a costume study for an advertisement to be used by a commercial firm, his customer. He engages a model, and after having taken the photographs for the purpose of carrying out the order, makes one or two further exposures for himself under the idea that, if he does not offer these to his customer, he obtains the rights in them himself and can make use of them in other directions. When he does so—we are describing an actual case—he finds that his customer objects on the ground that the photographs are so closely similar to those taken in execution of his (the customer's) order that they are an infringement of these latter.

Under the now repealed Copyright Act of 1862 it was clear from Section 2 that, so far as copyright is concerned, a photographer was within his rights in doing as above described. The Section, which is entitled "Copyright not to prevent the representation of the same subjects in other works," declared that "nothing herein contained shall prejudice the right of any person to copy or use any work in which there shall be no copyright, or to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene or object." This provision, however, does not occur in the present 1911 Copyright Act, and, in fact, it is difficult to discover anything in the Act which represents an equivalent liberty to create copyright separately as the property of the photographer and the customer in such circumstances as those which we have taken for our example. On the other hand, the Act defines copyright as the sole right "to produce or reproduce" the work or any substantial part thereof, etc. We cannot help thinking that the word "produce" is not used without some significance attaching to it, and it may be thought that the framers of the Act had in their minds such cases as these in which an artist produces a subject which he then embodies in a pictorial form (drawing or photograph) for a customer. If we draw this inference from the use of these words, then it is obvious that any further photographs which are made of the same subject (providing that they are closely similar to those made for the customer) would be an infringement of the latter. Unfortunately for this view of the Act's definition of copyright, the only case in the Courts which we know of as bearing on the point does not support it. In the High Court in August, 1917, a judgment was given by Mr. Justice Peterson in a case arising out of a dispute between two postcard publishers. Publisher A had produced a picture postcard representing a soldier reading the day's orders, which ran: "Eight hours drill, eight hours route march, either hours trench work." Underneath the drawing was the sentence "Then we have the rest of the day to ourselves." Another publisher, B, had issued a postcard of a similar kind, which also depended for its humour on the inscription below the drawing "Rest of the day to ourselves." On publisher A taking action against publisher B for infringement it was held that there was no copyright in an idea, but only in the expression of an idea, and that on this score the two cards were dissimilar. The case, however, is not quite on all fours with that which we have instanced. For one thing, we imagine that the two drawings differed considerably, but, more important, the originals were independently created by different people. It is in regard to this latter point that a photographer involved in such problems as these will, we think, be most securely guided.

For even if we do not stress the view which appears to be justified by the definition of copyright in the present Act, namely, that copyright involves production as well as reproduction, due attention must be paid to the particular circumstances. In the case which we have taken as an example we think there is an implied contract, quite apart from considerations of copyright, to the effect that the photographer is applying his services and facilities wholly to the customer in producing an original work from the life model, and that, therefore, the production of other versions of the subject closely resembling those which he supplies for the use of the customer is a breach of that implied contract. From this point of view it is quite conceivable that the High Court judgment of 1917, which we have quoted, would have been very different if the two originals had been produced by the same person and had been supplied to different publishers, and if the action had been taken

on grounds of breach of contract. So far as the wording of the present Act is concerned, comparatively little help is given towards the solution of these difficulties. There is certainly nothing in the Act which suggests that a photographer is infringing anybody's rights when he takes a photograph of some natural scene or view from such a view-point that the result is practically identical with photographs which previously have been taken. It is, as we have suggested, chiefly when the question of breach of implied contract enters into the case that attention must be paid to it, at least, as much as to that of copyright law. The only judgment within our knowledge which bears directly on these questions is one in a United States Court in a case in which a photograph of a girl was made and copyrighted as "Grace of Youth," and all rights therein sold by the artist. Two years afterwards the same photographer took a picture of the same model in practically the identical pose of the first picture, except that the girl was smiling and had a cherry stem in her mouth. In the legal dispute which arose in reference to this latter work, which was called "Cherry Ripe," it was held that any other artist could have used the same material and have made a new picture so closely resembling the copyrighted one that it would pass for it without infringing the copyright. But when the same artist did this, he was considered to be using the experience gained in taking the first picture in making what was in many ways a duplicate of his first picture, the rights in which he had sold. In these circumstances the law did not protect him.

A CALCULATOR FOR TIME DEVELOPMENT.

[In the following article in "American Photography" the author, Mr. Leo Kraft, describes a scale or calculator for ascertaining the time of development by making appropriate allowance for the temperature of the developer and the development speed of the plate when using a particular pyro-soda formula.]

It is always more or less difficult, in the dim red light of the dark room, for even the most experienced photographer to judge by inspection of the plate just when development is complete. This is more particularly true in the case of the average amateur photographer who develops plates or films only occasionally, and whose views cover a wide range of subjects, as even with all other conditions the same, two different types of views may appear to be quite different at the time development is complete. If one is using different makes of plates or films or double-coated plates, any inspection method of development is still more difficult, as the various emulsions will cause the negatives to appear different at the time development is finished. Some plates fix out more in the hypo than others, which is a further condition to be allowed for. There used to be a belief that a cold developer produced thinner negatives than a warm developer, but this was largely due to the fact that development was often stopped too soon, which might readily happen when attempting, by inspection, to determine the proper development time. Given two negatives of the same view, on the same brand of plate, and developed with the same developer, at different temperatures within the range usually met in practice, if the development has been timed on the basis of the temperature it will usually be impossible to distinguish between the negatives, while the prints made from them will be almost identical.

One other idea which many photographers still cling to, is the notion that it is possible to put individuality into a negative by special manipulation during development. Ruling out a very small percentage of special views, I think this idea may be readily disproved to anyone's satisfaction by simply trying the experiment. Views containing extreme contrasts, such as interiors showing brightly-lighted windows, should have special development, but practically all other views, from portraits to copies of black and white drawings, need no special treatment. These subjects certainly constitute over 95 per cent. of the average negatives. I have developed portraits on many different plates and films, groups, flashlights, landscapes, and even copies of black and white drawings on process plates, all in the same developer by a strict adherence to the rules and methods to be described, and not only have the results been entirely satisfactory in every case, but I am positive that the general run of negatives has averaged much higher than would have been obtained by any other method.

Any number of arbitrary rules have been proposed to enable one to determine just when the plate should be removed from the developer, but the very fact that these rules are so varied shows that little reliance is to be placed on any of them. That there is, however, no need for any uncertainty in development has been clearly demonstrated many times, and if the developer is mixed according to the same formula, its action on any brand of plate will depend only on the temperature. That is, the time required for complete development will vary with the temperature in a definite and fixed ratio for the developer used, and having determined this ratio once and for all, the time required may always be definitely known. Different brands of plates require different times for development, but this also will be a fixed quantity to be determined once and then used thereafter.

Two general methods have been proposed for determining the time required for development, one of which is known as the factorial method and the other as the time and temperature method or thermo-method. The factorial method is based upon the ratio which the time required for the first appearance of the image is assumed to bear to the total time required for complete development. With the factorial method, the time measured for the first appearance of the image, after the developer is applied, is multiplied by a known number or factor, the result being the total time required for development. Suppose that with a developer whose factor is known to be 12, it is found that the first appearance of the image occurs 16 seconds after the developer is applied. Then 16 times 12 gives 192 seconds or practically 3¼ minutes, the time required for complete development.

This factorial method has many drawbacks, and the writer does not recommend its general use. With an over-exposed plate the image may appear almost immediately after the developer is applied, and if the factorial method is used, development will be stopped too soon. With an under-exposed plate, the reverse is true, the image may not appear for some time after applying the developer, resulting, if the factorial method is used, in over-development. Often with correctly exposed plates, one view may contain bright high-lights which will appear before any other part of views, again resulting, when the factorial method is used, in incorrect development. Also, with the same developer, different brands of plates may show different factors, while changing the dilution of the developer or the temperature may also change the factor.

Development carried out by the time and temperature method will result in uniformity of negatives, producing perfect negatives with correctly exposed plates, and with under-exposed or over-exposed plates the best negatives possible under the circumstances. As there is no need for inspection of negatives during development, the process may be carried on in absolute darkness if required. It will also be possible to adjust the process so as always to obtain any desired degree of contrast to suit one's particular taste or to accommodate any special printing process.

There have been several time and temperature methods

proposed. but they may be roughly divided into two classes; in one class the *time* of development for different plates at the same temperature is always the same, the dilution of the developer being varied for the different plates. In the other class, the *developer* is always used at the same strength, the time being varied for the different plates. With the time and temperature method I am describing, the developer is always used at the same dilution for dish use, and always the same for tank use, the tendency of different brands of plates to develop faster or slower being taken care of by a development speed number previously determined. The tendency of a plate to develop rapidly is indicated by a high speed number, while the tendency to develop slowly is indicated by a low speed number. When this speed number is once determined for any brand of plate it need never be varied, unless for some special reason one desires to change the degree of contrast, in which case decreasing the speed number will give greater contrast, while increasing the speed number will give less contrast.

In order to facilitate the determination of the proper development time by the use of the speed numbers the development calculator illustrated herewith has been prepared. It may be made by pasting figs. 1 and 2 on a piece of fairly

SPEED NUMBERS

Plate or Film	Speed Number
Hammer Red Label	25
Kodak Film	20
Portrait Film	30
Seed Graflex	25
Seed 26X	30
Seed Process	5
Speedex Film	15
Standard Orthonon	35
Standard Polychrome	30
Stanley 50	35

INSTRUCTIONS

Time-Temperature Method

Add speed number of plate to temperature of developer. Set index arrow marked "Tray" or "Tank," as the case may be, at this sum, and the hand will then point to total time for development.

Factoriel Method

Set developer factor at time required for first appearance of the image, and the hand will then point to total time required for development.

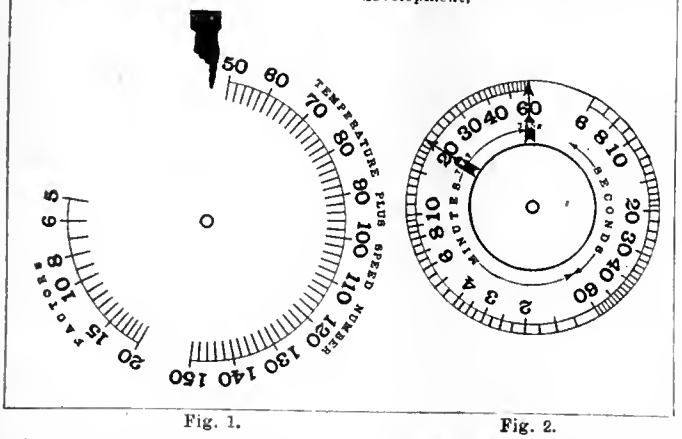

Fig. 1. Fig. 2.

stiff cardboard, then cutting out the disc, fig. 2, and mounting it by means of a rivet or eyelet, so that the centre corresponds with the centre indicated on the rectangular piece, fig. 1, and so that the disc may be rotated on this point. To use the calculator, the previously determined speed number is added to the temperature (in degrees Fahrenheit) of the developer, and the disc on the calculator turned until the tray or tank index arrow, depending on the dilution of the developer, points to this sum. The hand will then point to the time required for development, this being the total time the plate should be in the developer solution. The speed numbers for most makes of plates and films will range from about 25 to 40, those for roll films being somewhat lower. These speed numbers will give negatives which print well on medium grades of gaslight paper and which will enlarge on bromide or other enlarging papers. The appended table of speed numbers should be used only as a guide, and each operator should make his own table to suit his own particular requirements.

Determining speed numbers is not difficult, and, as the average photographer uses comparatively few different brands of plates or films, it is easily done. To determine the speed number, take a plate or film which has been given, as nearly as possible, the correct exposure, and develop it with the developer properly diluted for tray or tank, as the case may be, noting the developer temperature. Carry development to what appears to be the correct point, determining this by any method the photographer is in the habit of using, and note the total time the plate is in the developer. Now turn this disc on the calculator so that the hand points to the development time found by the above trial. The proper index arrow will then point to the sum of the temperature and the speed number. Then if the temperature of the developer is subtracted from this sum the result will be the speed number which is to be used in the future for that brand of plate. After the negative is finished and a print made, one can decide whether development was correct, too long, or too short, and vary the speed number accordingly in another trial. Usually two or three trials should definitely determine the speed number for any brand of plate.

Suppose, for instance, that with a certain brand of plate it was found that $3\frac{3}{4}$ minutes were required to correctly develop the plate in the tray to the required density when the temperature of the developer was 65 degrees. Turning the disc on the calculator so that the hand points to $3\frac{3}{4}$ minutes, the tray index arrow will be found to point to 95. Then 95 less 65 (the developer temperature) will give 30 as the speed number of that plate, which should be used in the future for all plates of the same brand.

The calculator must only be used for determining development by the time and temperature method when the developer is compounded after the formula given herewith, which is for the well-known pyro-soda developer, which is in almost universal use and one of the cheapest to prepare. It has good-keeping qualities, but we do not recommend mixing up more than about one month's supply at one time, although we have repeatedly used developer much older than this with good results. The impurities in the water and the amount of air in solution affect the keeping qualities to a great extent, the sulphite solution being particularly subject to spoiling, which will result in stained negatives. With any developer, the best results are always to be obtained when the solutions are fresh. Boiled or distilled water may be used when preparing solutions, but unless the water supply is very bad this is not necessary. As a rule, if the water is fit for drinking it will be suitable for making up the solutions. The water for diluting the stock solutions just before use should have stood in the dark room long enough to have attained a constant temperature, as otherwise the temperature may change during development, although seldom, except with the tank, enough to materially affect results. The 4 ozs. of developer for tray use is sufficient for a 7 × 5 plate, and the quantity shown for tank use is correct for the 7 × 5 Eastman plate tank. If different quantities are required they should, of course, be diluted in the same proportion.

The developer to be used with the calculator is compounded as follows:—

Stock Solution A.	
Water about	8 ozs.
Potassium metabisulphite	55 grs.
Potassium bromide	7 grs.
Pyrogallic acid (pyro)	330 grs.
Water to make	16 ozs.
Stock Solution B.	
Sodium sulphite (dry)	600 grs.
Water to make	16 ozs.
Stock Solution C.	
Sodium carbonate (dry)	425 grs.
Water to make	16 ozs.
For use in dish take	
Solution A	3 drs.
Solution B	3 drs.
Solution C	3 drs.
Water to make	4 ozs.
For use in tank take	
Solution A	2 ozs.
Solution B	2 ozs.
Solution C	2 ozs.
Water to make	64 ozs.

Always use the developer immediately after mixing the stock solutions and water together, as it will not keep when mixed. Always use fresh developer for each tray or tankful of plates. Do not try to use the developer a second time, as the chemicals which have been dissolved from the plate during the first use will affect the time and quite often the colour of the negative. Even with present-day retail prices for chemicals the cost of sufficient developer for one 7 × 5 plate in the dish is only about one cent, and it would be poor economy to run the risk of spoiling a plate costing some ten times this amount by using the developer a second time.

While not recommended for general use the calculator may also be used with the factorial method. For this purpose set the disc so that the time required for the first appearance of the image is opposite the known factor of the developer, and the hand will then point to the total time required for development. The calculator shown in fig. 3, B, is set for the following data :—

Factor	11
Time for appearance of image	18 sec.
Total development time	3 min. 20 sec.

When using the factorial method the calculator may be used with any developer, providing the factor is known. With the pyro developer compounded after the formula given above the factor will be found to be about 11.

After many years experience in developing plates and films, and after experimenting with a great number of development methods, the writer unqualifiedly recommends the time and temperature method of development as being the most accurate that he knows of. The photographer of small experience can make no mistake in adopting it, while the photographer of somewhat more experience will probably be surprised to see the difference in his work if he will abandon his inaccurate methods and adopt the time and temperature method for determining the developing time. The writer believes that the trend is more and more away from the slipshod, hit-or-miss methods of former days, and that there is a definite tendency toward precision in all photographic operations from the calculation of the exposure to the making of the finished print. If solutions are compounded with reasonable care, a strict adherence to the time and temperature method as shown by the calculator will be found to give uniformly good results, eliminating all tendency to over-develop or under-develop, even when the plate has been improperly exposed.

LEO KRAFT.

THE MOTOR-CYCLIST PHOTOGRAPHER.

DURING the course of a year the average provincial photographer has many country outdoor appointments involving journeys of, maybe, five, ten, twenty, or even more miles from the studio.

If the operator is dependent on railway or public bus transportation half a day, or more, may elapse between the times of his departure from and return to the studio.

It often happens that railway time-tables do not fit in with the hour of the appointment, and a good deal of time is wasted on the outward and return journeys. The remarkably rapid development of the post-war country motor-bus affords an alternative to travelling, inasmuch as their times of departure and return may be more frequent or suitable to particular needs; moreover, one may alight at any point on the route traversed, and, it should be remembered, some of these stages are inaccessible by rail.

In either case, however, a loss of valuable time is almost inevitable, for, apart from time lost while waiting, neither train nor bus puts one down on the doorstep of the address sought; indeed, it frequently happens that some distance remains to be covered on foot.

During the present period of trade slackness and reduced staffs it may be most essential that the operator should be able to return to the studio at the earliest possible moment, therefore arises the question as to how these distant jobs may be undertaken and executed with as little inconvenience and as much expedition as possible.

The Question Answered.

I can assure those who are situated where straggling, outlying districts abound that there is no more inexpensive or expeditious aid to the keeping of distant appointments than the light-weight motor-cycle.

It is not so many years ago since a journey by motor-cycle might have been regarded as much in the nature of an uncertain expedition; the motor-cycle of to-day, however, is probably as reliable as any other form of speedy travel, consequently the motoring photographer may compile his own time-table; furthermore, the machine carries rider and apparatus to the very door of his clients.

One may start out on a five-mile journey, as I have done, say, at 1 p.m., expose half a dozen plates, and return, ten miles in all, in time to keep a studio appointment at 2 p.m. Similarly, it is possible to travel a distance of twenty miles out, execute the business, return, and be busy in the studio in less than three hours. These examples demonstrate not only the value of the motor-cycle as a time-saver, but the opportunity afforded the single-handed operator for undertaking extra appointments when occasion demands.

Helpful Details.

Personally, I ride a 2½-h.p. two-stroke—commonly known as a "potter-bus," on account of its light weight and handiness for "pottering" about on short trips—and I can particularly recommend this type for the purpose.

The weight of my machine is about 120 lbs., therefore no undue exertion is required to handle it; the simplicity of its engine renders it exceedingly reliable mechanically, therefore no special mechanical knowledge is necessary, and this is a most important point to the non-technical motorist.

In my own case I have covered 2,500 miles during the past six months, and no mechanical trouble has been experienced over this distance, while, as regards tyres, 2,300 miles have been ridden since the encounter of a puncture. Running costs, including fuel, oil, and wear and tear, work out at approximately 6s. per 100 miles; compared with the railway charge of 14s. 7d. it will readily be understood that a machine soon pays for itself, apart from saving the photographer money in the form of time.

Keeping an Appointment.

While writing about motor-cycles, I have to bear in mind that this is a photographic journal, and I can only insert so much mechanical matter as is necessary to interest the photographer. Assuming, therefore, that I have so far interested the reader who has something to do with country outdoor work, it may be presumed that further details on the keeping of an appointment by motor-cycle will be welcome.

First of all I make certain that the machine itself is in good order in every respect, then the camera is made ready. After thoroughly cleaning the interior of the dark-slides, so that dust and vibration may not result in a pinhole plague, the camera—up to whole-plate—and tripod are mounted and securely strapped on a "Tan-Sad" spring pillion seat, which is fixed on the carrier. This completes the equipment of the machine; the remaining preparations are the personal matter of dress.

To many minds motor-cycling is synonymous with a rider covered in oil and mud. Long-distance riding and a dirty machine—a machine which flings both oil and dirt—is certainly not conducive to a presentable business appearance. I have the good fortune to be the owner of a machine which, while offering no special protection, runs cleanly in the dirtiest of weather, and it at no time flings oil on to the clothing. A good set of waterproof overalls are advisable, however, as a protection against dust or rain. Personally, I remove these outer garments on reaching my destination, so that I may appear decently tidy.

Starting Out.

I have remarked that the motor-cycle is trustworthy, the one uncertainty is the ever-present possibility of tyre trouble, and, if the time allowed for the outward trip is cut down to a minimum, a puncture may be awkward. Therefore, it pays to keep the tyres in good condition; moreover, it is policy to base the time of the journey on a seventeen-mile-per-hour basis, then, in the unlikely event of a deflated tyre, it should be possible to make a repair and still arrive on time by travelling the remaining distance at speed, if necessary. Fortunately, one is not so liable to tyre troubles on short distances, any loss of time on a long journey can be regained, as pointed out, by a higher average speed. The return trip is made in quick time.

Conclusion.

I should not have done my subject justice had I not suggested the utility of the motor-cycle for those who make a speciality of dashing off to photograph accidents and the like either for the Press or for display purposes. In such cases speed is everything, and for these unexpected happenings the motor should always be kept in readiness for instant use. Finally, business apart, motor-cycling is a most healthy and invigorating pursuit for sedentary workers such as we photographers are. "PRUDENCE."

FORTHCOMING EXHIBITIONS.

February 18 to March 4.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

March 1 to 6.—Birmingham Photographic Society. Particulars from the Hon. Secretary, P. Docker, Medical Institute Buildings, Edmund Street, Birmingham.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 8 to 9.—Birkenhead Photographic Association. Particulars from the Exhibition Secretaries, Messrs. Longstaff and Trace, 33, Hamilton Square, Birkenhead.

March 14 to 16.—City of London and Cripplegate Photographic Society. Latest date for entries, March 4. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, C.2.

ACCELERATED HYPO-ALUM TONING.

SINCE writing in the "B. J." for February 10, I have carried out further tests with the idea of working out a practical method, giving the advantage of speed without unduly adding to the work or trouble.

Having done this to my own satisfaction, I am setting down the procedure for the benefit of hypo-alum users who care to take advantage of it.

The hot bath used is compounded with 1 lb. of hypo and 4 oz. of white (potass) alum, dissolved in 80 oz. of boiling water. The amount first put into use is ripened by the addition for a few minutes of about 18 sq. inches of old or spoilt gaslight paper per oz. If bromide paper is used, less suffices. The method of ripening advocated by Messrs. Illingworth and others is at least as good, but I find the addition of old paper to be quite satisfactory. This ripening is only done with the first dishful, the stock being kept unripened. Each day, immediately before heating up, the bath is well stirred and a few ounces are poured away, the deficit being made up with fresh stock. In this way it is possible to keep the bath working well indefinitely. No water bath is necessary, as the prints tone rapidly while watched.

For fixing the prints, a plain hypo bath will simplify matters. From this bath the prints are removed to a solution of sulphuric acid, of a strength of about 8 per cent. Weaker acid will serve, but I have had the best results when using stronger solutions. Above 10 per cent., however, there is a tendency to carry too much acid into the toner, with the result that powerful fumes are given off. Those acquainted with sulphuric acid will not need any caution about its use, but it may be as well to point out that the strong acid is dangerous and must not be allowed to touch the bare fingers or be diluted by the pouring in of water. Water falling on strong sulphuric acid will cause violent ebullition, with possible personal damage. The acid must always be poured into the water. I mix a winchester of the weak solution, which can be used in perfect safety, the concentrated stock bottle being kept out of the reach of young assistants.

After a good turn over in the acid, prints are put into the toner, where with constant turning they tone very rapidly. In a very hot bath I have had tones in as little as thirty seconds.

If prints are fixed in compound fixing baths, it is safest to rinse them and re-soak in plain hypo before treating with acid. For this purpose a strong solution—I have tried saturated and 30 to 40 per cent. strengths with satisfaction—can be kept and used repeatedly until it is all used up. One minute will suffice in the hypo bath provided the print is well immersed and turned, but two or three minutes will do no harm unless the print is already over-fixed, when some little reduction may possibly occur. I limit the immersion in both hypo and acid to a maximum of two minutes at 65 deg. to 70 deg. F., and in no case have I had any reduction or degradation.

For the acid treatment, hydrochloric will serve equally well, as will certain other acids, but there is the advantage in using sulphuric of not introducing new compounds into the toning bath, this acid being related to the salts already there. Traces of hydrochloric acid might reasonably be expected to produce common salt in the bath, and possibly other things, and in time the composition of the bath might be so altered as to affect the tones. No difference is discernible, however, in two prints which have been treated with different acids, and toned at the same time, or at least I have not been able to get different tones this way.

With regard to stains, I believe that there is less risk of spoils with the accelerated treatment, but stains caused by improper fixing are not entirely obviated. I have had a print half-toned in the usual way apparently refuse to go further until taken out and treated with the two baths, when on re-immersion in the toner it promptly finished toning; other prints which were manifestly "stained"—suffering from bluey patches where presumably fixing had not been complete—refused to answer to any treatment. If the same kind of stains can be produced by "cooked" gelatine, as was suggested in America some few years ago, the cooking also affects the image, for, when intending to produce such marks by overheating, I got them after the whole print had toned.—THERMIT.

THE will was proved last week of the late Mr. Sigmund Guiterman, of Aldermanbury, London, E.C. £45,712.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 13 to 18 :—

CAMERAS.—No. 4,312. Roll-film photographic cameras. A. J. Dennis, V. W. Edwards and Houghton-Butcher Manufacturing Co., Ltd.

APPARATUS.—No. 4,525. Apparatus for treating photographic plates, films, etc. T. J. Doyle.

DRY-PLATES.—No. 4,218. Photographic dry-plates. K. Wiebking.

MOUNT CUTTING MACHINE.—No. 4,546. Photographic mount, etc., cutting and bevelling machine. F. Worthington.

PRINTING-BOXES.—No. 4,694. Photographic printing-boxes. A. P. Keen.

STEREOSCOPIC CINEMATOGRAPHY.—No. 4,185. Apparatus for taking stereoscopic cinematograph photographs and projecting pictures on a screen. A. Wilson.

CINEMATOGRAPHY.—No. 4,788. Cinematograph apparatus. C. Farmborough.

CINEMATOGRAPH-PHONOGRAPH.—No. 4,842. Manufacture of sound records and synchronisation of same with cinematograph films. H. Knudsen.

CINEMATOGRAPH-PHONOGRAPH.—No. 4,851. Combined moving-picture and sound-reproducing apparatus. H. Knudsen.

CINEMATOGRAPHY.—No. 4,453. Cinematograph, etc., screens. R. H. Parkinson.

CINEMATOGRAPHY.—No. 4,714. Device for eliminating flicker in cinematograph apparatus. M. E. Richardson.

CINEMATOGRAPH-PHONOGRAPH.—No. 4,596. Means for synchronisation and reproduction of sound with cinematograph. W. Ross.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY.—No. 145,478 (March 31, 1919). The invention is a process for the manufacture of a cinematograph film in colours which comprises the taking of negative images by a cinematograph camera laid on its side so as to give images with their horizontal lines parallel to the length of the film, the speed being twice the ordinary speed of, say, fifteen images per second in order to obtain two images through two coloured screens in the time usually occupied in taking a single ordinary image, or three times the ordinary speed of, say, fifteen images per second in order to obtain two images through two coloured screens in the time usually occupied in taking a single ordinary image or three times the ordinary speed in order to obtain two images and a blank. The increase in speed obtained by the inclusion of a speed-multiplying gearing in the camera. A positive is made from the negative by projection, the two films being arranged and moved relatively at 90 deg. the printing being effected in such a manner that the two images on the negative are together projected to produce on the positive film two side-by-side reduced images with their horizontal lines transverse of the film and which occupy the surface corresponding to an ordinary image.—Cesar Parolini, 3 Boulevard Carnot, Le Vesinet (Seine and Oise), Paris, and Gustave Perron, 9, Avenue Taillade, Paris. (Particulars of the process are given on another page in the "Colour Photography" Supplement.)

MULTI-PRINTING FRAMES.—No. 174,128 (September 18, 1920). The object of the invention is to provide apparatus adapted for use *inter alia* in producing multiple designs, images or impressions on plates, lithographic stones, etc., for the purpose of printing in one or more colours therefrom by any of the usual processes.

The apparatus includes a framework or carriage adapted to travel over a table supporting the sensitive surface and supporting an auxiliary carriage adapted to travel transversely of the main carriage so that the auxiliary carriage may be brought into a position directly above any part of a registering frame on the table. From the auxiliary carriage are suspended legs which can be lowered into contact with a thick covering sheet of plate glass laid on the negative in the frame on the sensitive surface

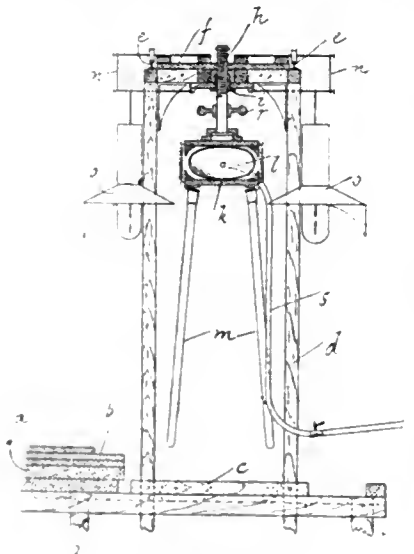

Fig. 1.

so as to hold the negatives rigidly in position. There is interposed between the freely hanging legs and the auxiliary carriage an inflatable member, on inflation of which the legs are forced by the pneumatic pressure against the covering plate glass. The

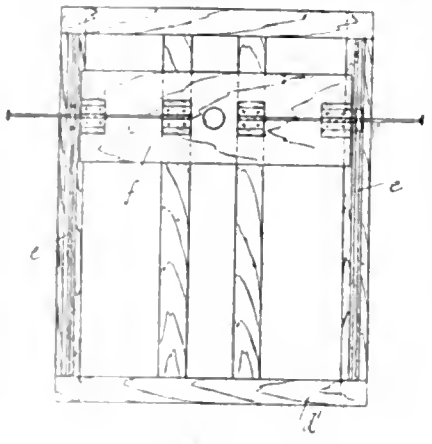

Fig. 2.

auxiliary carriage preferably carries also electric lamps for printing.

In the drawings, *a* is a table along two outside edges of which are arranged bars *b* bolted to the table supporting rails *b*¹ for

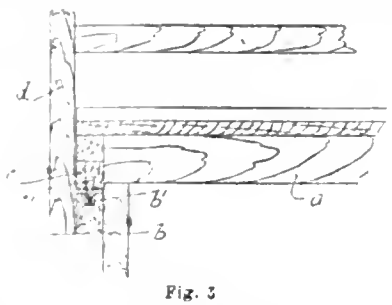

Fig. 3.

rollers *c* mounted in laterally extending bars *c*¹ of an upright carriage *d*, the bars *c*¹ tending to prevent the raising of the carriage from the table. On the upper surface *d*¹ of this carriage on rails *e* is mounted an auxiliary sliding carriage *f* in such manner that the auxiliary carriage may travel transversely of the

main carriage. Suspended from this auxiliary carriage by means of a screw threaded rod *h* engaging in a screw threaded bush *i* attached to the carriage is a separable spring-connected housing *k* containing an inflatable elastic vessel *l*, and from the lower portion of this housing are suspended depending legs *m*. From a framing *n* attached to the auxiliary carriage *f* are suspended electric lamps *o* which travel with the carriage.

On the table top a^1 is placed on a slate bed *p* on the sensitive surface a registering frame *q*, such as shown in figs. 4 to 7. This frame is fitted with slots (not shown) for subdividing bars q^1 formed with true right angles into which the negative from which the impression is to be made on the sensitive surface is inserted. On the top of the negative is placed a covering plate glass (not shown). The subdividing bars may be adjusted in position by inserting in different slots.

In using the apparatus the negative is inserted in its compartment in the registering frame and fixed therein by a strip of wood. The covering plate glass is laid thereon and the other

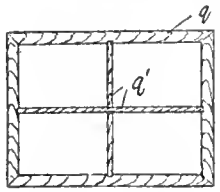

Fig. 4.

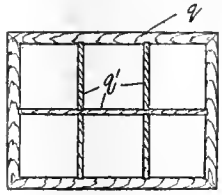

Fig. 5.

spaces not being utilised in the frame are covered to protect the sensitive surface beneath the frame. The carriages are now traversed until the depending legs are in position above the covering glass plate. By means of the wheel *r* the screw-threaded rod is turned until the legs bear on the covering glass plate, whereupon air is forced through the pipe *s* to the inflatable vessel and the depending legs caused to press more firmly on the covering plate glass. The electric lamps are switched on and the printing carried out. When the printing operation is completed air is allowed to escape, the wheel *r* is turned until the legs are clear of the covering glass plate, and the carriages moved along

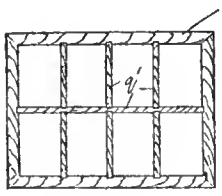

Fig. 6.

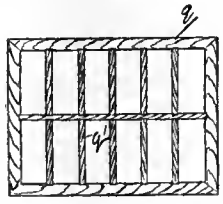

Fig. 7.

the table out of the way to permit access to the surfaces treated.

It will be understood that for multi-colour printing the different colours may be impressed in register on successive sensitised surfaces by using the same registering frame for each different colour so that they may be printed in register.—Henry Robert Eason, 38, Sylvan Road, Wanstead, London, E.11.

In a further patent, No. 174,309, of the same inventor, and having reference to the same type of apparatus, the claim is for a registering frame, applied to the sensitive surface and to receive negatives or positives, and formed with true right angles. Such frame is fitted with adjustable subdividing bars, also forming true right angles.

The following complete specifications are open to public inspection before acceptance :—

Cinematography. — No. 175,265. Cinematographic film strips. Pathé Cinema Anciens Etablissements Pathé Frères.

Cinematography.—No. 175,266. Storage reels for cinematograph films. Pathé Cinema Anciens Etablissements Pathé Frères.

Reproduction Device.—No. 175,284. Reproducing device for photographically recorded phonograms, especially tone films. J. Engl, H. Vogt and J. Massolle.

Dry-Plates.—No. 175,296. Photographic dry-platea. K. Wiebking.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

Dupli-tized.—No. 420,051. All goods included in Class 39. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials.

New Books.

Byepaths of Colour Photography. By "O. Reg." Edited by William Gamble. London: Percy Lund, Humphries and Co. 5s. net.

This is a very uncommon book, almost unique, we think, in the literature of colour photography or even of any branch of photography. For reasons which no doubt are desirable and sufficient, the author has chosen to issue his work under a pseudonym, but that which has been selected appears to be a deliberately thin disguise. Anybody who has no more than a superficial reading of the development of colour photography will quickly pierce it. However, as the author and editor desire to preserve the semi-anonymity we will respect their wishes.

The book is really a collection of thirty-six short papers, which we learn were written at different times and were intended for separate publication. The greater number relate to the history and technical design of the one-exposure three-colour camera, and more particularly to the optical methods for obtaining three identical images by the use of prisms, reflectors, etc., behind the one lens. We think it is fair criticism of this part of the book to say that the subject is illustrated rather than treated in such an exact way that the would-be constructor of a camera of this kind can apply the information without a good deal of experiment on his own part. Nevertheless, it is clear that these chapters embody the results of a very great deal of experimental work by the author, who, however, seems not to have the facility of making clear what are precisely the optical conditions which need to be fulfilled. We turned to Mr. Gamble's introduction in the hope that we should find there a more explicit statement of the conclusions to which the author has come, but in that we were disappointed. Nevertheless, experimenters with one-exposure cameras will find a very great deal in the book of profit to them in their studies.

From the historical standpoint we do not think the author is as well qualified by knowledge and temperament as he should be for such a task. For one thing he has a habit, which is very irritating to the historical student, of criticising inventions without naming their authors; and our confidence in his historical notes is rather disturbed by coming across such palpable, though minor, errors as these in the first paragraph on page 65, where it is stated that Dr. Vogel's discovery of orthochromatism originated from experiments on gelatine dry plates; or that on page 95 which refers to Farmer's mercury-iodide intensifier.

The later part of the book contains chapters on colour-sensitising, adjustment of plates and filters, exposure, and the making of three-colour prints and transparencies. Here again the author is evidently writing from the results of his own practical experience and brings forward hints and formulæ, some of which we cannot remember to have seen before. For example, he recommends the following variation of the Farmer reducer as free from tendency to eat away the half-tones of a negative. The negative is immersed for a few seconds in a mixture of 3 per cent. freshly made ferricyanide solution, 10 per cent. soda carbonate, 10 per cent. ammoninm nitrate, and 10 per cent. sodium chloride, after which it is rinsed and fixed in fresh hypo.

In conclusion, it is not possible to pass over without comment the strain of sarcasm or bitterness which characterises many passages. We are reminded of the mental atmosphere, partly querulous, partly self-satisfied, of that early work of Gissing's, "The Private Papers of Henry Ryecroft." Mr. Gamble, whose work of editorship, we strongly snspect, has largely amounted to re-writing, might well have exercised a mollifying influence in many places.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MARCH 6.

Wombwell P.S. "Rouen." J. R Wigfull.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 28, the president, Dr. G. H. Rodman, in the chair.

The President declared open an exhibition of prints selected from the Annual Print Competition It will be open during the coming month, and will well repay a visit. He then called upon Mr. Thomas Bell, F.R.P.S., to deliver his lecture, entitled "Present Day Portraiture."

Mr. Bell open his lecture with a short talk on the position of portraiture to-day as compared with the time of D. O. Hill, remarking that although there had been vast improvements in the portrait studio, we have to go back to the style of D. O. Hill to produce real artistic photographs. He pointed out that since his time we had gone through definite pictorial stages, namely, small, full and three-quarter length figures, cabinets with marble hall backgrounds and the present plain setting. Next he referred to the so-called Rembrandt lighting, the fuzzy gum bichromate print and the most martistic sketch portrait. Any man can work a camera, said Mr. Bell, but it takes an artist to portray character. This is a thing which cannot be taught but is a gift. He said he was glad to see retouching was gradually being diminished, with the result that faces did not appear to be boiled and inflated with a bicycle pump. Good photography and bad drawing do not blend, the same may be said of sketch portraits and backgrounds worked in on the negative. He expressed pleasure in the fact that we were working back to plain, straightforward lighting, and that people realised the beauty in cast shadows. In the dull lighting which has been the fashion recently the pupils of the eye dilate, producing a ghastly stare. Posing has become natural, and lost the stiff wooden appearance produced by stock poses. He regretted the cutting out of the hands in present-day portraiture, also stating that in his opinion the best photographers of to-day are beating the living painters in posing, having so many more opportunities with different sitters. He recommended the study of Raeburn for suiting the style of lighting to the subject. For instance, his portraits of men had a strong and definite light, for women the outlines were not as clearly defined, and for children the lighting is beautifully soft.

Mr. Bell then showed a very fine collection of slides of prints by British and foreign workers. In the discussion which followed he stated that a long exposure gave the best results, as the expression varied, whereas Dr. Rodman said in opposition that the fine results of Mr. Walter Thomas were obtained by means of a reflex camera, focal-plane shutter and flashlight.

A hearty vote of thanks was accorded to Mr. Bell in the usual manner, and thus ended a very pleasant and instructive evening.

CROYDON CAMERA CLUB.

Mr W Bullock, hailing from the Willesden Photographic Society, gave a very interesting exposition, entitled "Picture Making with the Camera." Being an artist with the brush before he took up photography as a means of pictorial expression, added value to a well-reasoned preliminary paper which supported the cause of "control." The modest lecturer, however, is by no means a militant extremist, and by medium mixers of the super type might be regarded as unsound, as admissions were made that the ethics of some particular procedures were open to debate.

Apart from inculcating art maxims which continually embellish photographic discussions in varied phraseology, but essentially are the same the lecture was of real utility in showing what can be done in dressing up an indifferent bromide print to exhibition standard Mainly, this is effected by modification, without material alteration, of the high lights and shadows, combined with excursions of a more questionable nature.

For picking out high-lights he employs a small brush charged with weak ferricyanide reducer, testing its action on waste prints or trial strip exposures The bromide paper must be just surface-dry, and the brush set in quill, not metal, which latter had afforded some remarkable effects in Prussian-blue. For large areas, cotton-wool is substituted for the brush.

Shadows are strengthened by Vandyke-brown and Payne's-grey tube oil-colours mixed in right proportions and thinned with spirits of turpentine and negatol This is applied with a sable-brush where required, and when the paint is nearly set, smoothed by gently dabbing with a small ball of cotton-wool. For graded tints over big spaces, such as sky, blacklead is employed, though it does not always match in colour, but employed as the first step to the finished article this does not matter.

For exhibition work he first makes a bromide enlargement, taking care no actual white or black is present. This is worked upon in manner described with other additions shortly to be mentioned. The composite picture is copied in the camera on a small plate, from which another enlargement is made and toned up to concert pitch.

Without suggesting that this procedure will not result in a loss of "quality" with certain classes of subject and type of negative, Mr. Bullock amply demonstrated that for much exhibition work loss of quality if any is negligible, and improvement in other directions considerable. He copies out-of-doors, inclining copy and

camera towards the sky in a soft light towards the evening, and employs Imperial "fine grain" ordinary plates, which, he said, are admirably adapted for the purpose, possessing, as they do, great latitude.

Originally he made the first enlargement on a large scale, with the idea that the bigger the print the less the hand work would show, but had found this to be unnecessary, and now adopts about one standard size larger than the final print. In both cases "ordinary" surface bromide papers are preferred.

At home he is the proud possessor of a veritable Madame Tussaud's collection stored in negatives all ready for introduction into pictures, which, whenever possible, are taken without any human element entering. Life is too short for combination printing, and a far simpler plan is adopted. A suitable figure is selected, enlarged to the right size on thin bromide paper, and when dry cut out with a sharp knife held so as to afford a slight bevel inwards, the back being smoothed down a trifle at the edges with the knife. The figure is stuck on the print, and, with care, no junction shows. If it does, a little work on the copy negative, and enlarged print therefrom, will remedy matters.

Another display of virtuosity consisted in replacing a distant view as seen through an arch at Gruyère (the place where the holes come from) with another of desirable character. The arch was cut out and stuck down on the view, and considerable pressure applied. This elegant feat interested the purists immensely, and, under more pressure, the lecturer admitted that purer forms of photography were known.

The discussion was prolonged, and up to best traditions in the lurid line. It can only be glimpsed at. Mr. Harpur was with the lecturer tooth and nail concerning the ferricyanide reducer, but reproved him for minimising the quality of the original negative. "Dash the negative!" exclaimed the naughty Mr. Jobling, overcome by the spirit of the evening. "Quality is of the utmost importance," firmly insisted the prior speaker. "Who is talking about *photographic* quality to-night?" inquired the utterly bewildered Mr. Coffin, in the innocence of his heart.

Mr. Sellors, temporarily forgetting his own bromoil sins and nigger minstrel business with bromide prints, prophesied a slough of moral degradation setting in, thanks to the lecturer's efforts on that behalf. The paste-on advocacy was painful in the extreme. A far better plan was a method suggested by Mr. G. E. Brown in an editorial in the "B.J." The bromide print and cut-out figure are adjusted to each other under water, squeegeed on to glass, and copied. How this method frees itself from the charge of immorality Mr. Sellors did not explain.

Mr. Salt congratulated the lecturer on having so ably demolished the title adopted by him, and then proceeded to go for everybody all round, the "tooth-and-nail" partner particularly. He was amply rewarded by drawing from Mr. Harpur the remarkable dictum that "art training comes quite naturally to the photographic pictorialist." Which accounts for a lot.

A most hearty vote of thanks was accorded Mr. Bullock, whose happy style of lecturing and pleasing personality contributed not a little to a highly successful evening.

THE NATURE PHOTOGRAPHIC SOCIETY.

The annual general meeting was held at the Royal Photographic Society's House, Russell Square, London, on February 25, 1922. The President, Mr. E. J. Bedford, occupied the chair. The report of Council and treasurer's financial statement were adopted, and showed the Society to be in a very satisfactory position. The officers for the ensuing year were elected as follows:—President, Hugh Main, B.Sc., F.Z.S., F.E.S.; vice-presidents, C. Edwards, Dr. S. Hastings, H. Irving, C. Kirk, J. J. Ward, W. M. Webb; committee, T. M. Blackman, W. H. S. Cheavin, R. Chislett, C. W. Colthrup, S. Crook, A. W. Dennis, R. Fortune, G. C. S, Ingram, C. J. King, W. H. Pratt, H. M. Salmon, A. E. Tonge; hon, treasurer, Hugh Main; hon. secretary, E. J. Bedford.

At the conclusion of the business meeting tea was served, followed by an open meeting for the exhibition of lantern slides. A large number, including natural colour slides, were passed through the lantern. In the evening a dinner took place at the "Florence" Restaurant, Rupert Street, W., Dr. G. H. Redman in the chair, and a flashlight photograph of the company present was taken during the evening.

THE CAMERA CLUB.

Mr. Arthur C. Banfield, on Monday evening last, read a paper on the Bromoil process, in which he put forward his views and experiences with a vigour and clearness which one expects from a technician of his calibre, and expert not only in his every-day profession of studio portraiture, but in mechanical and experimental work of many kinds. He boldly espoused the Bromoil process in declaring that if properly used and not abused it is one of the most beautiful processes which photographic science has given us. It depended upon the capacity of a moistened surface to absorb or repel a greasy ink as in lithography. A bromide print, which had been treated in a copper bleaching bath containing chromium, had its gelatine tanned in proportion to the amount of silver in the image, and, therefore, when a suitable ink was applied the original silver image could be built up again, if necessary, in absolute facsimile. But it was necessary that a reasonably perfect negative and a reasonably perfect print from it should be made. Mr. Banfield scouted what he thought was a common opinion, namely, if one had a "rotten" print, the best thing to do was to Bromoil it. Whatever developer was used, development should be fully carried out. A print or enlargement which had been over-exposed and the development of which had been stopped to prevent too great a density was useless for the process. He did not attempt to deal with the bewildering variety of bleaching formulæ. One which he had used exclusively for the past two years was:—

Copper sulphate	8 ozs.
Potass bromide	8 ozs.
Potass bichromate	200 grs.
Sulphuric acid	160 minims.
Water	100 ozs.

In making this stock solution the acid is first added to the water. His working bath was made by mixing 1 part of the stock solution with 5 parts of water, and bleached a print thoroughly in about 3 minutes. Used bleacher could be employed again by adding more stock solution to it so that its bleaching speed was maintained at the 3 minutes standard He found that the bleacher seemed to improve with age.

Prints were fixed after bleaching, and the washing before fixation required to be very thorough. for at least an hour in running water. Incomplete washing at this stage infallibly caused blotches and markings which could not be dodged in afterwards working-up. Mr. Banfield was strongly of the view that it was much better to bleach immediately after developing; there was a considerable saving of time, with a much smaller chance of getting stains. Each print, as soon as fully developed, was placed in a dish in running water, and the accumulated batch then washed for about a quarter of an hour. They could then be handled with safety by artificial light, bleached, fixed, and finally again washed for a quarter of an hour in a dozen changes of water before being hung up to dry The fixing bath should be 3 ozs. of hypo in 20 ozs. of water, in which the bleached print was turned over for 10 minutes. This method left no silver in the paper, so that the image was formed by a permanent ink on which any traces of hypo were without effect.

Mr. Banfield laid stress on safeguarding the gelatine surface from scratches, folds, kinks, or blisters. It was folly to hang prints over a line to dry. Also prints should be carefully freed from adhering globules of water by blotting off before drying. The best method of drying was to pin one corner of each print to the edge of a table or shelf so that the print hung freely suspended.

As regards the tools for pigmenting, Mr. Banfield again declared himself in favour of somewhat exceptional practice. The genuine fitch brushes were too expensive, and, moreover, were very liable to clog and to shed their hairs. He had found a serviceable alternative in the hog-hair brush, which was very cheap, a No. 4 of large size costing only 12s. 6d. and sufficing to ink up an 18 x 15 print in half an hour. Also the work kept beautifully clean, and the only disadvantage was the rather coarse grain. For large prints the open hog-hair grain was agreeable rather than otherwise, but for prints smaller than, say. 12 x 10, any coarseness could be easily removed by gently going over with a small dry fitch brush. The final effect was as if a fitch had been used throughout, except that there were no broken or strayed hair on the print.

For keeping the print moist during pigmenting he used a dozen

or so sheets of Fotonic or Robosal blotting paper, soaked in water and laid in a pile on a piece of slate. With a rolling pin as much as possible of the water was squeezed out. In summer it might be necessary to use the pad in a fully soaked condition, in which case a safe edge was provided under and along the edges of the print by laying down strips of old roll film (after removing the gelatine coatings) on the pad so as to overlap the print on each of the four sides by about half an inch.

The most important point of all was the soaking of the print before pigmenting. The key to this much discussed part of the process was that pigmenting was governed entirely by the amount of water which the print contained. The less water, the harder the ink must be, and *vice versa*. He found that the best practice was to soak for a minimum period at a constant temperature, e.g., 65 deg. F. After about three minutes the print would lie quite flat in the water, then holding the minimum amount of water With a very hard ink, the print was then in the best condition for pigmenting, and also the gelatine was in a better (harder) condition than if more soaked

In seeking to get over the troubles of pigmenting he had persuaded a friend to make for him a series of inks of two degrees of consistency, one extremely hard and the other very soft. By judicious use of these inks it was easy to suit the hardness of the ink to the amount of water held in the gelatine of the print.

Mr. Banfield described in detail his own practice in pigmenting A little hard ink was spread out thin on one corner of the palette, and a little of the soft ink on another corner. The hard ink was touched and worked out thin with a hog-hair brush, and then the print, after three minutes or so soaking at 65 deg. F., until it lay flat was put on the pad and free moisture removed with fuffless blotting paper The image should appear as a delicate matt when observed at a sharp angle. The brush charged with the hard ink was then applied firmly, when the image should appear very quickly and complete in all details at each stroke of the brush. This required a peculiar brush action only learnt by experience. It was difficult to describe, but the brush is held lightly, with the handle leaning in a forward direction, and is applied with a quick firm stroke, not exactly a dabbing action, but a quick firm pressure combined with a slight dragging action

If the paper, through having too soft a gelatine coating and therefore containing too much water for the hard ink, does not take the latter properly, the condition is evident at the first stroke of the brush, and the ink must then be softened, the brush is then very lightly applied to the patch of soft ink and then worked down on to the patch of hard ink already described. Only a minute incorporation of soft ink is required materially to affect the working. Mr. Banfield said little about methods of control in pigmenting, and in fact uttered the caution that excesses in this direction tend to cover a beautiful process with ridicule. A small still flat hog-hair brush was of great effect in touching, or even making, high-lights, but needed to be used sparingly. In portrait work it served for hatching a background. The brush required to be wiped after each stroke, or it would cause smudges. Vignetting could be done with a small sponge on the end of a glass tube, moistened with a mixture of petrol and water. Light accents might be put in on the dry print with soft rubber if broad, and with hard rubber if sharp, but such methods were easily abused.

In conclusion, Mr. Banfield referred to the extraordinary time sometimes required to dry a Bromoil print completely. Sometimes it required three months under ordinary atmospheric conditions. He had constucted a low temperature oven in which prints were held vertical at a temperature of about 100 deg. F. They dried within at most three days so completely that they could be dry-mounted without risk.

A VISIT FROM MR. J. J. ROUSE.—On Friday last we had the pleasure of a call from Mr. J. J. Rouse, Managing Director of Messrs. Kodak (Australasia) Proprietary, Ltd., who has been paying a short visit to this country, coming by way of the United States of America, and in the course of conversation we learned that he was one of the favoured few representatives from the Overseas Dominions who had the honour to receive an invitation to attend the wedding ceremony of H.R.H. Princess Mary on Tuesday last. By the time this note appears Mr. Rouse will be on his way back to Australia, viâ Paris and Marseilles.

News and Notes.

THE OPTICAL SOCIETY.—The next meeting of the Society will be held at the Imperial College of Science and Technology, South Kensington, at 7.30 p.m., on Thursday, March 9, 1922, when the following communications will be presented and discussed: "A Criticism of the Nodal Slide as an Aid in Testing Photographic Lenses." By T. Smith, M.A., F.Inst.P., and J. S. Anderson, M.A., D.Sc., Ph.D., F.Inst.P. "A Non-Polarising Spectrophotometer." By A. J. Bull, M.Sc., F.Inst.P. "The Photometry of Optical Instruments." By J. Guild, A.R.C.Sc., F.R.A.S., F.Inst.P. "A Projective Treatment of the Submarine Periscope." By T. Smith, M.A., F.Inst.P. "Some Measurements of the Stresses Produced at the Surfaces of Glass by Grinding with Loose Abrasives." By A. J. Dalladay, A.Inst.P.

KODAK DEMONSTRATIONS TO PROFESSIONALS.—Visitors to Messrs. Kodak's Liverpool depôt on Monday evening, February 20, were well rewarded with a capital demonstration by Mr. Lawrence. The large Church Street shop had been prepared for the evening, having the counter moved back, additions to the seating accommodation, and the installation of studio and dark-room necessities. The evening opened with a dissertation on the salient points of films this being followed up by the making of a number of film negatives. A couple of shielded and diffused ½-watt lamps supplied the light for the portraits, very keen interest being displayed in a spot-light lamp which the demonstrator used for additional effect. Brought into play on the shadow side of the face, the spot light gave a very noticeable addition of "live appearance" to some of the pictures. In one case, though, it appeared to approach opposition to the main lighting, thus neutralising somewhat the truth of delineation as given by a single light source. But, as Mr. Lawrence explained, spot lighting is a new thing, at present in the experimental stage. It was evident, however, that very effective results are to be got by its use and judicious control. A point worth notice is that better results seem to be got by a condensed or focussed beam than could be obtained with any kind of diffused or reflected light. The evening finished with the making of some prints on etching brown, and the ease with which these were done —under parlour conditions—was a convincing proof that there is nothing for anyone to be afraid of in this new and high-class paper. The demonstration was well attended, the available space being comfortably filled with Liverpool and other Lancashire photographers, and a welcome surprise was accorded the audience by a speech by the President of the Lancashire Master Photographers on the Society and its future aims and ambitions. Mr. Winter also added to the evening's success by posing for some of the pictures.

BRITISH INDUSTRIES FAIR.—The Eighth Annual British Industries Fair, under the Department of Overseas Trade, opened last Monday at the White City, Shepherd's Bush, London, W.12, and remains open until March 10. The industries represented here, apart from those at the Birmingham Fair, held concurrently, include paper and stationery, leather and fancy goods, toys and games, silver and electroplate, scientific and optical instruments, photographic and musical instruments, glass and china ware, etc., etc., and unusual efforts have been made by the organisers to ensure a large attendance of buyers. In all 48,000 invitations have been sent out to overseas buyers, and advertisements have also been inserted in foreign and overseas trade and daily journals. A new departure has also been made by our own post office in the fact that all outgoing mails have included in the cancellation stamp the words "Visit the British Industries Fair, 1922, February 27 to March 10," which is now familiar on inland letters. The number of exhibitors (1,400) this year is slightly less than last year, but the total space occupied is the same. Photography is not so well represented this year as one would wish to see it: the allied industries, however, are well to the fore, particularly cinematography. The well-known firms of Butcher, Dallmeyer, Ross, and Sinclair have very attractive exhibits of cameras, lenses, and lanterns, mainly cinematographic. Johnson & Sons Ltd., and Burroughs Wellcome & Co., exhibit their well-known chemicals, developers, etc.; the Westminster Engineering Co., Ltd., arc lamps and other specialties; and Ellis Grafer has on view an attractive selection of photographic enlarging, developing and other machinery. Photo-

graphic albums and frames there are galore by many firms in the stationery section, and an exhibit attracting considerable attention is that of E. B. Fry, Ltd., who have a special show of passe-partout materials, including a gauge for putting on binders—a distinct novelty, also a cleverly-designed printing box for films, and a new variety of celluloid masks. A truly wonderful exhibition when one realises that no exhibitor may exhibit articles other than those of his own—and of British—manufacture.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

IMPROVING CAMERA CASES.

To the Editors.

Gentlemen,—All the camera cases I have seen—even the more expensive hide—are lacking in one respect. They are not fitted with studs on the bottom corners such as are found on the cheapest suit case.

A useful little tip is : Procure two pairs of ladies' rubber revolving heels, and four bifurcated rivets about 1 or 1½ in. long, drill a hole in each corner and attach the rubbers, and finish by flattening down the rivet ends inside ; a washer is not necessary. Not only does this fitting prevent wear, but it keeps the case dry and clean in wet weather. There are four (costing 1d. each) on my case, and they have been there since 1911.

T. P. MacNally.

Tuam, Co. Galway.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. H.—(1) The best process for chocolate tones on bromide prints is the uranium toner, but it requires more than ordinary care in use, and even with the best attention is liable to give results which are not very permanent. Varnishing the prints with ordinary celluloid varnish is a very great means of improving permanency. (2) About the best imitation of P.O.P. is obtained by the hypo-alum bath.

C. H.—The little book, "Commercial Photography," issued by our publishers, contains quite a few hints on the photography of engineering subjects. So far as we know, there is not any other work on this subject except an American one, "The Commercial Photographer," by L. G. Rose, published by F. V. Chambers, 636, Franklin Square, Philadelphia, Pa., U.S.A., price $4. This is a very much larger and an excellent work.

M. P. T.—All processes of restoring a faded print are very risky, and it is quite possible to make the print worse than it is. A P.O.P. toning bath would not help matters. By far the best thing that you can do is to have a reproduced print made by a firm of experience in such work. Such a firm is Messrs. Jeffery and Boarder, 55-56, Mattock Lane, West Ealing, London, W.13, who, to our personal knowledge, are most successful in this specialty.

S. A. T.—You will do no good by raising your roof unless you raise the floor to a corresponding extent. Rolled (ribbed) plate glass would soften the light, but would not change its direction. Perhaps the best arrangement would be to instal a large cheval glass, about 40 × 30 inches, to serve as a side light. We have seen this used very effectively in a top-lighted studio. You could probably borrow such a glass from a tailor or dressmaker to make an experiment with.

J. R. S. —If you used the oil colours specially made by Winsor and Newton, 37-40, Rathbone Place, London, W.1, for transparency work you could easily get results as good as, or better than, the sample you send, and which arrived cracked. The sample, however, is evidently coloured with dyes, which are quite good enough for the purpose of advertisement transparencies. You should try the sets made up for this purpose by Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.2, or the Vanguard Manufacturing Co., Maidenhead.

L. E. A.—We are afraid it is not possible to discover a reason for the difference in tone from the particulars stated. Generally a great secret in getting uniform results by hypo-alum consists in having a large quantity of ripened bath in use, say not less than 4 or 5 gallons, strengthening this bath by moderate additions of freshly-prepared hypo-alum mixture as prints are toned in it. Another point is equal heating of the bath. The vessel containing the hypo-alum mixture should preferably not be heated directly by a gas ring, but be placed in a larger tank containing water kept at the required heat to produce a temperature of 120 deg. F. in the toning solution.

T. P. E.—The development of the cinema film was so gradual that it would require almost a short treatise to answer your questions, which, in fact, cannot be answered in the specific form in which you put them. If one defines the "invention" of the cinema film as a commercial introduction, then the year 1895 is the date, in which year MM. Lumière first made the cinematograph a practicable thing by the invention of an efficient projector. Really you should take the opportunity of looking at chapter 3 of "Living Pictures," by Hopwood and Foster, for an answer to your questions. You can see this book in the Library of the Patent Office, 25, Southampton Buildings, Chancery Lane, W.C.2.

C. G. B.—Assuming that the maximum dimension of the film picture is 1 inch, and that the available distance of 1 foot is the distance from the film to the screen, the focal length of projection lens required for a projected image 18 × 18 inches is 0.6 inch. We do not know that such a lens is obtainable, and do not think it is. We suggest that you write to Messrs. Taylor, Taylor and Hobson, who have recently been specialising in cinematograph projection lenses. If they cannot supply, they can perhaps refer you to makers of microscope lenses suitable for your purpose, although we fear the optical difficulties of definition and illumination are somewhat serious. As regards using a longer focus, you could perhaps get a 1-inch lens, the use of which under the conditions specified above would give you a picture 10 × 10 inches.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3227. Vol. LXIX. FRIDAY, MARCH 10, 1922. Price Fourpence.

Contents.

SUMMARY.

Many useful hints on manners, dress, the getting of orders, and others matters of particular interest to receptionists are dealt with on page 140.

In a leading article we deal with the status of the professional photographer, who, as we point out, should imbue his mind with the settled conviction that he belongs to a worthy profession, the dignity and credit of which he is bound to maintain and to augment in every possible way. (P. 134.)

A chart for finding the depth of focus, with given aperture and distance of object, for any photographic lens, is illustrated and described in a communication from Mr. H. W. Lee, B.A. (P. 135.)

A simply constructed apparatus for measuring the focal length of the lens by what is known as the Clay method is the subject of an article on page 137.

Although acid fixing baths for bromide papers are commonly recommended in preference to plain hypo solutions, the latter have certain advantages which it is advisable not to overlook. (P. 133.)

Many contradictory and erroneous statements have appeared in the lay Press concerning the making of the exposures in Westminster Abbey on the occasion of the Royal wedding. On page 141 will be found details of how the fortunate operators really did accomplish the task.

The use of an optical enlarging apparatus in a modern lithographic establishment where poster and large work is executed is described in an illustrated note on page 141.

A very slight trace of hypo in a persulphate bath is sufficient to prevent or delay its reducing action. (P. 134.)

Many excellent portraits and landscape prints, the work of Mr. Arthur C. Banfield, are now on view at the Camera Club. (P. 142.)

At home portraits are often too contrasty. It is advisable always to use backed plates or films, to screen the lens, and to expose fully. (P. 134.)

The greatest caution is necessary when attempting to loosen a stuck lens cell. On page 133 will be found particulars of a simple device for, and method of, doing the work in the safest manner.

A non-actinic hand-lamp is a useful thing to have in a badly illuminated dark-room. A pocket electric torch may be made to serve. (P. 143.)

Photographic trade in Java, Leuco-bases in colour photography, and several other subjects are dealt with by correspondents in our "Correspondence" columns. (P. 146.)

Mr. W. L. F. Wastell, F.R.P.S., is to be the new president of the Royal Photographic Society. (P. 145.)

Stereoscopic cinematography is again the subject of a patent (P. 143.)

EX CATHEDRA.

Stuck Lens Cells. The detachment of one or other of the separate cells of a doublet lens, which has been allowed to get into this condition through careless keeping or has been bought as such, is often not the easiest operation, owing to the difficulty of getting a strong grip of the small projecting surface. A method of dealing with these obstinate cases which, we think, originated from one of the mechanical geniuses included within the membership of the Croydon Camera Club, is to cut a piece of wood of about one-quarter inch thickness, of width about twice the diameter of the cell to be removed, and of length about four times this diameter. A little way from one end of the piece of wood a circular hole, of diameter a shade larger than the outside diameter of the cell, is cut with a fret-saw. The hole should be of such size that the cell can be just slipped tightly within it. Then, by means of two cuts with a saw a strip of wood about half an inch in width is cut away so as to leave an open space between the circular hole and the further end of the piece of wood. When thus completed, the appliance somewhat resembles the "button stick" largely sold during the war for slipping under the button of a soldier's tunic as a protection of the latter whilst the former was being polished. If now the lens cell be inserted in the circular aperture in the wood and the two separated ends of the piece strongly gripped in the hand, the cell is most firmly held and can be readily unscrewed.

* * *

Fixing Baths for Bromides. Fixing baths made up according to one or other of the "acid" formulæ have become so universally popular that it seems frequently to be taken for granted that a bath of this kind is the necessary practice in the making of bromide prints. Such, however, is not the case; and indeed it may be said that for more than one reason a plain solution of hypo is to be preferred to any acid fixing bath for the fixation of bromide prints. One reason is that hypo, when used by itself, without the addition of alum, sulphite, or any of the usual components of an acid bath, goes further so far as fixing is concerned. It is sometimes urged in favour of the acid type of bath that it does not become stained in use, and for that reason can be employed for a larger number of prints. But we believe that this is a fallacious argument, and that the use of an acid bath is one of the most common causes of incomplete fixation of prints on development papers. The bath keeps practically free from colour until it is exhausted, or at any rate has reached such a stage of exhaustion that fixing takes place very much more slowly. On the other hand, a plain hypo solution, from the fact that it becomes gradually darker in colour as prints are fixed in it, gives, so to speak, a warning signal that it is reaching a stage when it has done its work and requires renewing

Home Portraits. Many workers in this interesting branch are disappointed with their results, finding them hard; that is to say, lacking in detail in both high-lights and deep shadows. In such cases it is usual to blame the lighting, but it is quite wrong to do so. If the lighting appeared agreeable to the eye there should be little difficulty in rendering it correctly on the plate, and as a rule failures to do so are due to under-exposure. With plates and films of the rapidity now available there is no excuse for under-timed pictures if a lens of reasonably large aperture be used and development not carried too far. It is almost imperative that backed plates or films be used, as few unbacked plates will stand the necessary exposure without a loss of detail in the high-lights. Another precaution which is neeessary when working against the light is to screen the lens so that no light, except that coming from the sitter, enters the lens. This is easily accomplished by suspending in front of the lens, by any convenient means, a large dark card with a cut-out opening, at such a distance that it just fails to obscure the edges of the plate. It is suggested that for a trial two exposures should be made, one three times as long as the other, and the results compared. This will afford much information for future work.

* * *

Finding in the Dark-Room. One of the great advantages of the ceiling form of light in the dark-room is the facility with which things can be found in parts of the room outside the range of the direct illumination from a lamp placed on the working bench. The gloom in which most of the space of a room is enveloped when this latter form of lamp is the only one employed is replaced by a degree of visibility quite sufficient for finding anything in the room, such as boxes of plates, or bottles on shelving, while at the same time there is no risk of fogging plates which may be in course of development. Those who do not care to go to the trouble of fixing a ceiling lamp have a very good substitute in an ordinary carbon filament electric bulb mounted in one of the usual holders which in turn is attached to a convenient handle. To the handle is fixed any convenient container of the lamp—light-tight, except that the front open end is covered with yellow or orange fabric. Supplied with current by a few yards of flexible cable, a non-actinic hand-lamp of this kind serves for discovering anything which may be sought in the dark-room without interference with other operations. Even those who have not the convenience of electric supply may obtain the same facility by making use of one of the cylinder forms of pocket electric torch after fitting a disc of yellow or orange glass behind the bull's eye with which these torches are usually fitted.

* * *

Reduction with Persulphate. There are still many people who find it difficult to make the persulphate reducer work evenly. There are several reasons for this, the principal one being a desire to hasten the process by acidifying the solution too strongly. If this be done to excess there is a tendency to patchiness all over the film, with the result of practically ruining the image. Any good sample of persulphate will reduce without the addition of acid, and in such cases the result will almost certainly be satisfactory, although the process may be rather lengthy. If no action be observed in fifteen minutes a trace of sulphuric acid may be added, care being taken that it is thoroughly diffused through the solution and the dish well rocked for a minute or two. If the negatives have been fixed in an acid fixer or a hardening bath has been used reduction will take considerably longer. It will also be found that very rapid plates take much longer to reduce than slow ones, the length of time taken to develop being practically an index to the proportional time necessary for reduction. A very slight trace of hypo is sufficient to delay or prevent reduction, by decomposing the persulphate, so that if this be suspected the solution should be discarded, and a fresh one made, which will usually work satisfactorily. Dark patches at the edges or corners are usually due to handling the plates with hypo-contaminated fingers.

IMPROVING THE PHOTOGRAPHER'S STATUS.

DURING the present period of industrial and commercial depression the photographer may usefully take stock, not only of pecuniary profit or loss, but of the less directly felt, though in the end sometimes more important, question of status. Amid many unpromising signs, gleams of hope begin to be discerned. Chief of these is a growing interest in this subject among photographers themselves. There is much truth in the assertion of psychologists that both bodily and mental well-being are largely conditioned by the patient's own impressions, and this is even more applicable as a maxim for business and professional prosperity. "Think success and you will be successful," was the advice given recently by the originally poor founder of a now colossal stores; and this is but a variant of the new auto-suggestive incantation, "Every day, in every respect, I am getting better and better." Now, matters of prestige and status are precisely of that semi-intangible kind capable of being influenced, for good or ill, by the worker's own mental attitude. To a great extent, what he thinks of himself will give the cue to what others think of him. As Mr. Bernard Shaw has said, the best way to effect great changes is to act as if they were already made.

To begin with, then, the photographer must imbue his mind with the settled conviction that he belongs to a worthy profession, the dignity and credit of which he is bound to maintain and to augment in every possible way. He should decline to be slighted or treated in a manner inconsistent with that ideal, or to undertake any work derogatory to it. The tale is told of a well-known West End worker, who happened to call on a would-be lady of fashion to make some suggestions relating to a large portrait in carbon which had been commissioned. She received him in the drawing-room somewhat ungraciously, remarking, "I think there is a tradesman's entrance." To which he replied, "I see you do not recollect me, madam. I am the photographer." Few, on the spur of the moment, could have made answer so effectively, yet—as it turned out—so inoffensively.

It is distinctly a gain that greater stress is now being laid on the scientific aspects of photography, and that these are approached in a more exact, orderly and methodical way than was at one time the case. The claims of the camera craft as a science are stronger than its title to rank as an art, or, rather, are easier to drive into the average person's unimaginative mind. Photography has long been called the handmaid of science, but this is a grave under-statement. It is but bare justice to assert that many of to-day's chief scientific advances are mainly, if not solely, due to photographic aid.

As regards portraiture, there is no doubt the general level is rising. The unfortunate incompetent, who opened a studio simply because he was a failure at everything else, has been decimated by the war and its aftermath.

Public taste is better also, and the more extensive display of good-class specimens renders rivalry hopeless, save by those who can produce results reasonably equivalent. This, indeed, is one excellent method of assuring the photographer's status, to see that bad work is everywhere drowned by its opposite.

A much-disputed point is the relative advantage of a doorway or a shop-window. Some of the best and most select workers prefer the former, which unquestionably looks more professional and less tradesman-like if properly handled. But it must be a handsome doorway, smartly and effectively decorated, yet with a refined taste; while the shop, if any, that happens to be adjacent, ought not to be allowed to overshadow it. A photographer's doorway should not look like the barely tolerated poor relation of a well-to-do shop. Again, it is a help to insist on the word "Studio." This should be inscribed above the door, or shown on a plate in conspicuous letters, preferably preceded by the photographer's name, to give a personal, and therefore more professional, touch.

From the standpoint of status, outdoor work is a stumbling block. In these hard times it would, of course, be the height of folly to refuse it, or even not to seek it. Many photographers, however, consider that it has a rather detrimental effect on a portrait studio, and take care to keep it as inconspicuous as possible, by choosing the quietest hour, relegating the actual exposure to assistants or trade workers, and never exhibiting samples, unless inside.

Though some will differ, it is more conducive to dignity to keep aloof from merely sectional societies or bodies, whether political or social, except those one takes a genuine interest in. The "local bounder" type of man, who belongs to everything, no matter how mutually antagonistic or contradictory, and is the bosom friend of everybody, begins to be distrusted and out-of-date. As Mr. Pirie Macdonald piquantly put it a little while ago: "You have got to be awfully careful about deceiving the dog."

In conclusion, a discreet *esprit de corps* should be cultivated. It is folly to criticise other photographers or their work before sitters, or to attempt cutting them out. It always recoils. One never finds a doctor doing that kind of thing. And, on occasion, when there is something vital to be gained, or fought against, the doctors show an impressive unanimity and act *en masse*. Photographers must learn to speak and act with equal unity. When they do, they will be accepted at their own valuation.

CHART FOR FINDING THE DEPTH OF FOCUS, WITH GIVEN APERTURE AND DISTANCE OF OBJECT, FOR ANY PHOTOGRAPHIC LENS.

(A Communication from Taylor, Taylor & Hobson, Ltd., Leicester and London.)

In constructing a method for finding the depth of field for any set of conditions, it is necessary to settle first what shall be the standard of definition. A usual condition for hand camera lenses of 5 or 6-in. focus is that the circle of confusion shall not be greater than 1/100 in. If now, a photograph with this degree of diffusion is enlarged to double its size, there will be an amount of diffusion 1/50 in., which may be disagreeable. The criterion here adopted is to allow a confusion of 1/1200 of the focal length. Thus, if a picture taken with a lens of shorter focus is enlarged to the size it would have if taken with a 12-in. lens, the degree of diffusion will not be greater than 1/100 in. There is a reason for this standard. Ten to twelve inches is the correct reading distance, and at such a distance 1/100 in. of diffusion would not be noticeable. If the picture is further enlarged, the distance at which it is viewed should be correspondingly increased for correct perspective, so that the further enlarging of the confusion discs would not be noticeable. In fact, this standard gives a uniform tolerance at the correct viewing distance, which is the distance at which the image is formed from the lens.

This standard has the further advantage of being in accord with that tolerable in cinematography, which, according to Mr. A. Lockett, is 1/800 in. for sharpest definition, and 1/400 in. "tolerable." Now the focal length of cinematograph taking lenses varies from 1¼ in. to 3 in. On the above scale the allowance will be from 1/700 in. to 1/400 in., so that the criterion may fairly be considered universal.

Now as to the mode of construction. The usual formula connecting object and image distance is

$$1/v + 1/u = 1/f$$

u being the object distance and v the image distance for a lens of focal length f. For a second object

$$1/v' + 1/u' = 1/f$$

We write capitals for reciprocals so that

$$V - V' = U' - U$$

If the two images are to be "sharp" their separation must not be greater than the circle of confusion multiplied by the F/number, i.e., $eN/1200$ where f/N is the aperture.

i.e. $V - V' = U' - U = VN/1200$

For let P and P' (Fig. 1a) be the images of two points O and O', P being at a distance v and P' at v' from the lens. Light from O focussing at P will form a disc $Q\,Q'$ at P', and if O is to be considered as sharply imaged at P', $Q\,Q'$ must not be greater than the maximum circle of confusion. In the extreme case, when O is the furthest point from O', that is "sharp" at P', $O\,O'$ is equal to $f/1200$. It is obvious that a point O'', nearer the lens than O' will also form a circle of confusion

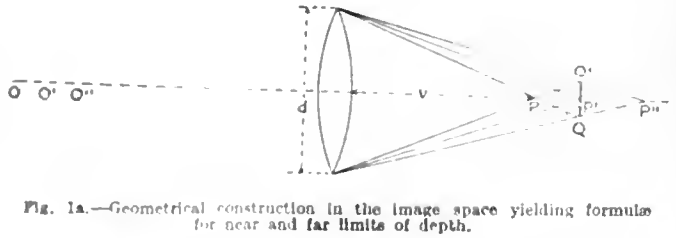

Fig. 1a.—Geometrical construction in the image space yielding formulæ for near and far limits of depth.

at P', focussing at P''. Then $O\,O''$ is the depth of field at O'. ($P\,P''$ is the depth of focus at P'.) From the drawing

$$\text{Circle of confusion } Q\,Q' = (v' - v) \times \frac{d}{v} = f/1200.$$

$$\text{Also } V - V' = \frac{1}{v} - \frac{1}{v'} = \frac{v' - v}{vv'} = \frac{f/d}{1200} \cdot \frac{1}{v'}$$

Now f/d is the F No., N

$$\text{so } V - V' = V'' - U = \frac{N\,V'}{1200}$$

$$\text{similarly } U' - V'' = \frac{N\,V'}{1200}.$$

In constructing the chart F (i.e., $1/f$) is marked off on the horizontal line OA and V on the vertical line OB. If a line OC at 45° to OB (fig. 1b) is drawn from the origin, horizontal distances from will represent $V - V'$, i.e., V. Now a line PN drawn from P

at a slope such that NQ/QP (= tangent of the slope of the line) = V/1200, then,

$$NQ = N/1200 \times PQ = VN/1200 = U' - U$$

and N gives U, i.e., the next distant point that is still in focus.

In constructing the chart it is convenient to use a table of reciprocals. The reciprocal of 10 is .1. Starting from the origin O a convenient distance is marked off, and the extremity marked 10, i.e., 10 in. focal length. The place for 12 will be 10/12 this distance from O, for 9, 10/9, and so on. The distances of the points 12, 10, 9, 8, 7, 6, being proportional to the reciprocals of those numbers. The same procedure

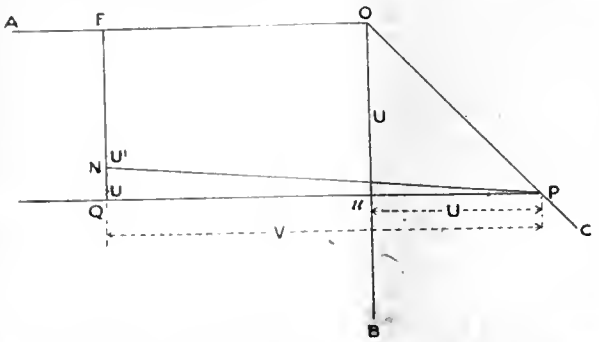

Fig. 1b.—Diagram of principle of constructing depth of focus chart in terms of reciprocals of object distances and focal length, and adopting a diameter of disc of confusion equal to 1/1200th of the focal length.

s made for object distance on the vertical line. Here it is convenient to work in feet, and any convenient scale can be chosen. To construct the line OC, a horizontal distance UP is marked off from OB (not shown in Fig. 2) equal to the reciprocal of the object distance *expressed in inches*, i.e. on the same scale as reciprocals of focal length have been drawn. Hence if object distances in feet have been drawn on the same scale as focal lengths in inches, the slope of OC against OB will be 1 in 12. In Fig. 2, focal lengths go from 6 in. to 12 in., and object distances from 8 ft. to infinity. Now the results will not change if both sets of figures are divided by any number, because the aperture

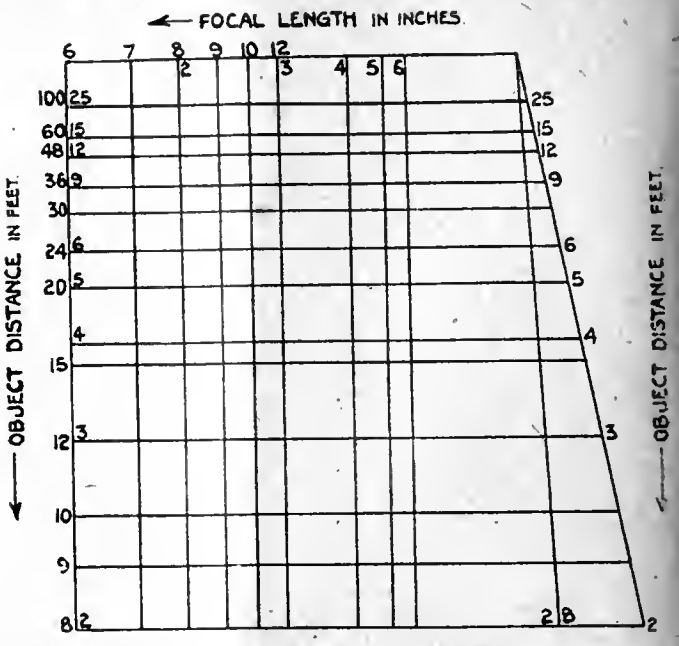

Fig. 2.—The chart—this part is the chart of distances and focal lengths plotted according to the rules explained by means of fig. 1b.

ratios are represented by angles, which will not change if Fig. 2 is reduced equally in both directions. Another set of figures is therefore shown representing focal lengths from 1½ to 6 in., and object distances from 2 ft.

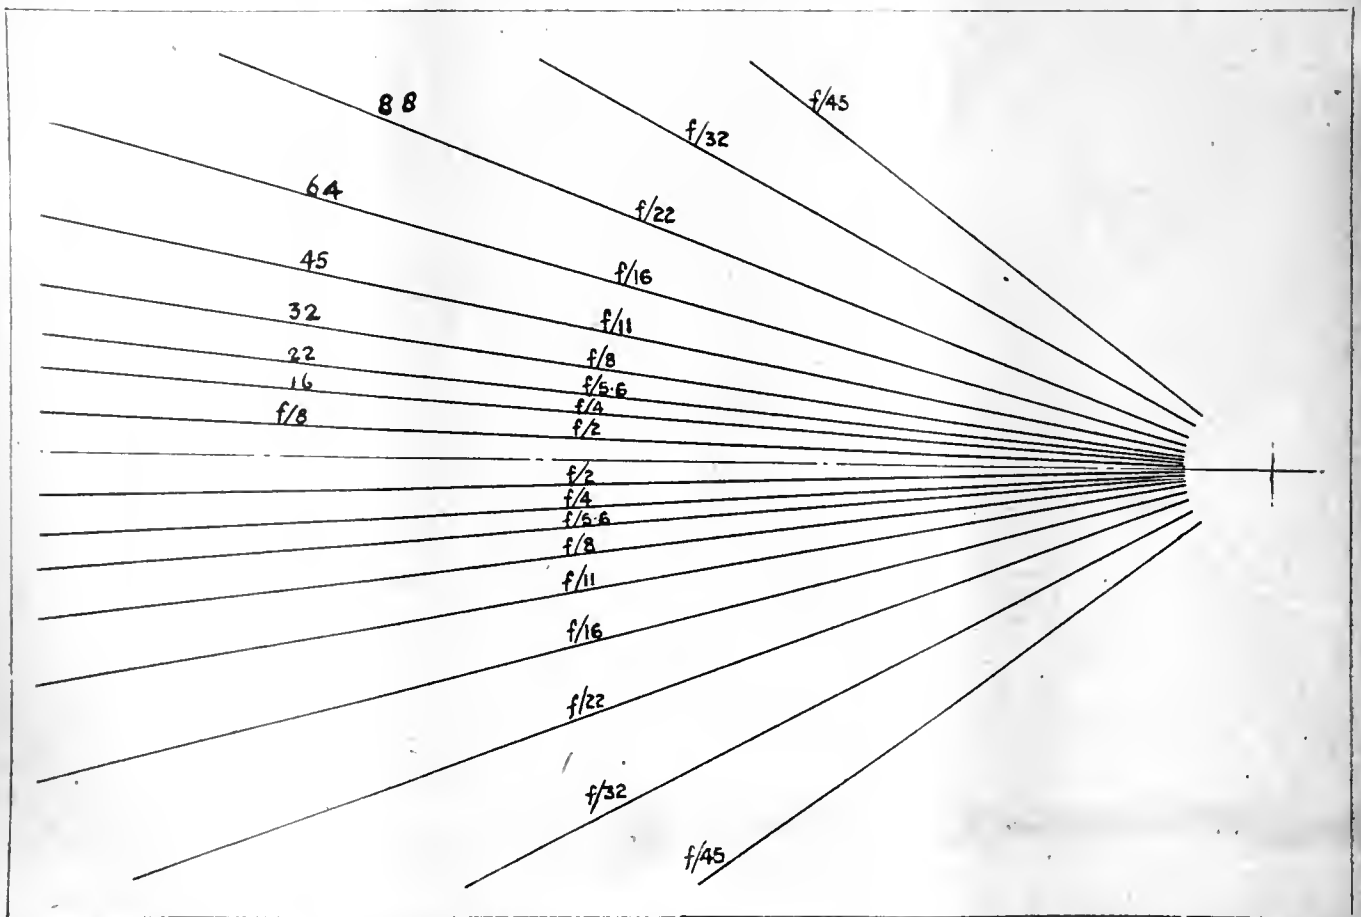

Fig. 3.—The chart—this diaphragm chart is drawn on transparent paper and in use is laid on fig. 2, as illustrated by the examples at the end of the article.

We must always remember to use *both* sets of inner figures, or both sets of outer figures, together. If we wish to use the outer set of focal lengths (i.e., 6 to 12 in.) with the inner set of object distances (i.e., down to 2 ft.), we have altered the relative scale of the figure and so require a new line, *OC*, which has a slope of 1 in 3 against the vertical, and we must use the *outer* set of figures on the aperture chart (fig. 3).

The construction of fig. 3 is perfectly simple, the line marked *f*/16 (e.g.), is drawn at a slope of 16/1200 to the horizontal line. In the case, however, above mentioned, of combining the outer set of focal lengths with the inner set of object distances, which is equivalent to increasing the vertical scale of fig. 2 four times, the vertical scale of fig. 3 must also be increased in this ratio so that *f*/8 becomes *f*/32, etc., according to the outer set of figures marked thereon. By combining these two scales the chart is diminished in size and works for *any* focal length (from 1½ in.), and aperture (from *f*/2) at *any* object distance (from 2 ft.). By the use of red and black ink, confusion between the two sets of figures is avoided.

The aperture diagram is drawn on transparent paper, so that it can be applied to fig. 2 for the solution of the problem under any set of conditions. Of course, it has to be seen that the central line *OA* (fig. 3), lies along a horizontal line of fig. 2. Corresponding to the two equidistant lines of fig. 3 bearing the same aperture number, are obtained two points that are in focus with the point focussed on, one nearer the lens and one more distant.

Let us consider a few examples that can be worked out by the chart. A group has to be photographed with a 10-in. lens, of which the nearest point is 20 ft. and the furthest 30 ft. What must be the aperture? Here, applying fig. 3, so that the centre travels along *OC*, and the axis keeps horizontal, it is seen that when the upper *f*/8 line cuts the 10-in. vertical at 30 ft. (both outer sets of figures), the lower *f*/8 line cuts it at 20 ft., the axis lying along 24 ft. Hence the lens should be focussed at 24 ft. and stopped down to *f*/8.

A 2½ in. *f*/4 cinematograph lens is working at 4 ft. What is the depth of field? Here we use both inner sets of figures and find a depth of focus from 3¾ ft. to 4¼ ft.

An object has to be photographed which is 2 ft. deep. At 5 ft. distance what must a 9½-in. lens be stopped down to? Here we use the outer line of focal lengths and the inner line of object distances, and consequently the outer *OC*. We see that the best place to focus on is at about 4 ft. 10 in., and the aperture must be *f*/32.

If a different degree of confusion is considered more suitable, the allowance is easily made, e.g., suppose a circle of confusion of 1/100 in. is considered passable, using a 6-in. lens. The latitude is here twice that allowed for in the chart. This means aperture numbers in fig. 3 may be divided by 2, i.e., *f*/8 considered as *f*/4, *f*/16 as *f*/8, etc. With this modification any desired degree of "sharpness" may be worked to

H. W. Lee, B.A.

CLAY'S METHOD OF MEASURING THE FOCAL LENGTH OF A LENS.

[The following description of an apparatus for measuring the focal length of a lens, which presents but little constructional difficulty, formed the concluding part of a lecture by Messrs. Vivian Jobling and E. A. Salt at the Croydon Camera Club, recently reported in these columns. Drawings have been made and text furnished to accompany them. They appear to cover fully all points likely to arise in the employment of this very ingenious and simple method.]

A highly ingenious and accurate method for determining the focal length of a lens, but now apparently but little used, was devised by Dr. R. S. Clay, and fully described by him in "Photography" of February 14, 1901. A subsequent lecture by him at the R.P.S. in 1904 is reported in the "B.J.," of August 25, pp. 748-749, and September 2, pp. 767-768, of that year.

The apparatus, as originally designed, was reduced to the simplest lecture-table form, and in reproducing it at the time the necessity of refinements became apparent for practical work. Accordingly we have modified the apparatus constructionally mainly on obvious lines, adopting a turntable capable of taking lenses large and small and of varying type, from a tiny R.R. to a large portrait lens. A centering arrangement among other minor, but essential, alterations has also been added.

The method depends upon the well-known fact that if a lens is turned, or swivelled, on a vertical axis which passes through the node of emergence, no movement on the focussing screen occurs when a distant object is focussed. The distance between the node and the focussing screen is then the focal length of the lens. A practical illustration of this principle is the panoram camera.

Difficulties arise, however, in applying the principle to determining the focal length of a lens. It is not easy to shield the screen from stray light; windows may not command a distant view, and if they do, atmospheric conditions are often not conducive to its sharp portrayal, especially if there be no clear-cut object included. A collimator can replace the distant object, but requires great accuracy in adjustment to avoid error, and is best left alone by the average man.

In the method devised and described by Dr. Clay a mirror replaces the distant object. Fig. 1 shows in rough sketch form the modified apparatus designed by us. A small hole illuminated from behind is fitted with cross-wires or equivalent. An adjustable turntable and superimposed carrier carry the lens (in error shown reversed in fig. 1, but correctly in fig. 4), and an adjustable mirror inclined at a slight angle is behind.

Light proceeding from the illuminated hole passes without deviation through the lens, and is reflected back by the mirror just above the hole, as shown by the lines A and B.

When a sharp image of the cross-wires is formed above the hole, and, *at the same time*, no movement of the image occurs when the turntable is swivelled on its pivot, then the horizontal distance between the cross-wires and a vertical line

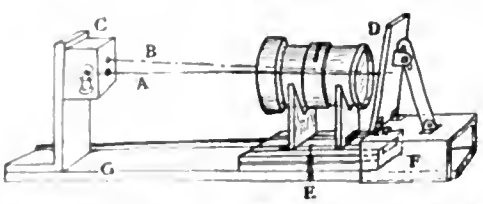

Fig. 1.—Diagrammatic sketch of apparatus for measuring focal lengths.

coinciding with the axis of the pivot is the focal-length of the lens under test, whose node of emergence is immediately over the axis of the pivot.

The cross-wires being at the principal focus of the lens, the light emerges from it, and is reflected back by the mirror in parallel rays, and thus a distant object is replaced in very ingenious way.

Moreover, as Dr. Clay pointed out, by employing a mirror in lieu of a collimator or distant object, adjustments are made with at least twice the accuracy. Firstly, as regards the displacement of the image when the lens is swivelled in any other position, and, secondly, as regards the image of the cross-wires coming in and out of focus when advanced or retreated.

By reversing the lens the other node is found, the distance between the two nodes (a minus quantity with "crossed nodes") being the optical "no man's land," with which we are not now concerned.

The Apparatus.

The apparatus in its essentials consists of a long baseboard with projecting pin towards one end; a turntable drilled to

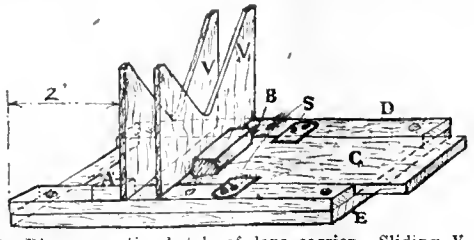

Fig. 2.—Diagrammatic sketch of lens carrier: Sliding V shown partially withdrawn as used with a small lens. Slide is held by pressure of the two metal springs S.
A.—Two stops fixing V to guides, ¾ x ¾ x ½ in. B.—Stop fixing V to slide, 1½ x ½ sq. C.—Slide, 7½ x 2¼ in. D.—Guide strips, 7½ x ¾ x ¼ in. E.—Base, 7½ x 3½ x ¼ in.

take the pin swivels on the baseboard. The turntable is provided with side-pieces or guides, between which the lens-carrier slides to and fro. The latter is also fitted with guides to take a sliding piece the whole length of the carrier, to

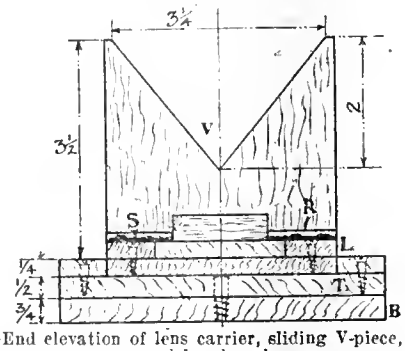

Fig. 3.—End elevation of lens carrier, sliding V-piece, turntable and baseboard.
B.—Baseboard. L.—Lens carrier. S.—Springs. T.—Turntable. R.—Sliding V cut away to clear springs.

which one V-support is fastened, as shown in figs. 2 and 3. The other is attached on each side to the guides on the lens-carrier, as shown in fig. 2. Behind it is an adjustable mirror supported by a bridge which spans the baseboard.

At the other end is the cross-wire carrier with rising and

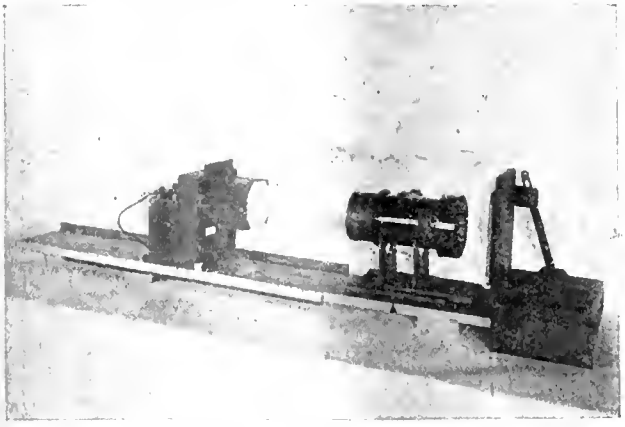

Fig 4.—Photograph of the apparatus.

falling front to permit of centering with the lens. The advanced position of the cross-wires is necessary if short foci lenses are to be tested; otherwise the carrier will foul the turntable. When advanced or retreated the carrier is pressed against a guide, shown in fig. 4, a graduated scale, and an index or pointer on the carrier being provided the other side. A clear glass "flashlight" bulb of 15 mm. diameter forms the illuminant run off an accumulator or dry-battery.

The apparatus has been designed to allow of plain-sailing construction by those least skilful with tools, who will find that by making exact paper patterns or drawings of the parts requiring them no real difficulties will arise. It may be modified in detail to any extent, provided essential features are retained. As a matter of fact, with the model illustrated in fig. 4 some oddments were pressed into service. The cross-wire carrier, for instance, was largely composed of a rising front taken from a Marion's "Radial" hand-camera to take 7 × 5 plates, quite a relic of the past. The photograph and sketches cover nearly all the ground as regards design and dimensions, but the following constructional notes may be of service to those glad of a little assistance at every step.

The Baseboard.

The length of the baseboard purely depends upon the focal lengths of the lenses to be tested, and is easily determined. Stout stuff should be employed, not less than ¾ in., and heavy cross pieces glued and screwed underneath. The board is then planed flat. If a carpenter is employed, test his work by laying a straight-edge across.

The Turntable.

The turntable (7½ in. × 5 in.) is of good ½ in. wood planed flat. A central line along its length is drawn and three holes bored, one central and two 1½ in. distant on each side. The latter will occasionally be found useful when respectively testing landscape lenses with the node behind and clear of the lens, and with lenses, like the Aldis and Cooke, which have their nodes well to the front.

The pivot is fashioned out of an engineer's brass screw about 1 in. × 3-16 in. The head is turned down to the diameter of the shank and rounded at the top. The baseboard is preferably "tapped" to receive it. It is necessary that the pivot be a close but not a jamming fit in the holes,

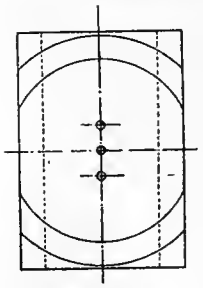

Fig. 5.—Sketch of turntable showing paper bearing strips on under side and alternate pivot holes.

for any play is almost fatal to accurate measurement. In the absence of a lathe any depôt undertaking repairs to motor cars will soon do the needful, and, having bench-drills, with screws, drills, and taps to gauge, a satisfactory job results.

Two pieces of thick smooth paper are glued or seccotined underneath the turntable, as shown in fig. 5, and any inequalities removed with fine glasspaper. The paper is given a coating of celluloid varnish, blackleaded, and polished.

The Lens-Carrier.

The lens-carrier must slide easily between the guides on the turntable, but without tendency to side-shake. It is to be noted that the two flat springs (fig. 2) bearing on the sliding-piece carrying one V-support must project but slightly, so as not to foul the block to which it is attached when drawn to the right. For the same reason this V-support is slightly undercut, as illustrated in fig. 3.

Should any difficulty be found in cutting the V's accurately they can be roughly done, and made larger. Protruding zinc strips can be cemented on (inside) and adjusted to correct position by laying on a paper pattern, and finally screwed down through holes previously drilled. For small lenses such a plan presents advantages, owing to the thinness

of the bearing surface. With a centre line drawn on the base and repeated on the sliding piece, with corresponding vertical lines on the V-supports, alignment is easy. The carrier, it may be remarked, is a slight modification of and an improvement on the one in the photograph.

The Bridge-Piece.

For a baseboard of 5 in. across the span of the bridge is about 7½ in. clear, the height just sufficient to clear the lens-carrier. The mirror is of ¼ in. plate, 6 in. long by 5 in. high, and, from a local dealer, cost 1s. cut to size. With a mirror of this thickness no trouble due to double reflection arises. The way in which it is held is obvious in the diagrams. In the photograph the mirror is shown on an independent support, which is unnecessary; the fitment happened to be at hand, and was utilised.

The Cross-Wire Carrier.

Any form of construction can be adopted for the cross-wire carrier, provided that the cross-wires have sufficient rise and fall to centre them vertically with the smallest and largest lenses likely to be tested. The protruding box is 3½ in. square, and faced with white paper or thin card on which a horizontal line is drawn midway. The projection of 3½ in. permits of focal lengths from 2 in. and under to be measured. Two slips of stout smooth paper are stuck under the base to act as runners, and one strip on the side next the guide, all three being treated in manner just mentioned.

If a small camera fitted with rising and falling front is available, its conversion may be easy if a sliding base with stop is employed, so that the camera can be replaced on the base in invariable position.

This is only necessary if a fixed graduated scale forms part of the apparatus. It can, however, be dispensed with, but in this case the turntable will probably have to be raised so that the top of the pivot be on the same level as the lowest limit of the cross-wires. A steel rule held horizontally will then read the distance between them and the pivot.

In any case the rising and falling front must operate truly at right-angles to the baseboard, which can be tested with a set-square.

Centering.

A lens is taken and both combinations removed, one being replaced with a card disc with small central hole. The lens barrel is placed on the V-grooves with the card towards the cross-wire carrier, which is brought up almost touching, taking care that both carriers are parallel with the baseboard. The front is either raised or lowered until the horizontal line drawn on the paper bisects the hole in the card, which is pricked through or otherwise marked, and the centre of the cross-wire aperture thus recorded. The front of the box is unscrewed, and, starting about 9/16 from the centre, circles are described in ink about ¼ in. apart to the edge of the box. A ¼ in. central hole is then drilled, and the inside cut away so as to permit the electric bulb to partly enter. It is screwed into a miniature barrel holder held by a thin brass strip forming a bridge-piece, and also one electrical contact.

The Cross-Wires.

A 1-in. square of acid-etched glass (or circle preferably, if it can be cut) is varnished, or retouching medium applied to the clear side. A mask of black paper, with a circular aperture of 3/16 in. (rather under than over), is seccotined to the etched side with the aperture central. Across it on the other side, in india-ink or "Photopake," bold lines and dots are made as indicated in fig. 6, and when dry fine lines and dots are scraped away with a needle for critical focussing. A small piece of very thin white paper exactly corresponding to the black mask is coated with celluloid varnish and stuck down on the clear side with its aperture coincident with that of the black mask. Just above the cross-lines a small area is coated with Chinese-white water-colour, quickly applied, which gives a nice surface for focussing upon. The square (or circle) of glass is then stuck to the front of the box *with the upright cross-line central*, centering being easy by inspection through the back. If a frosted electric bulb be used, or other means adopted for diffusion, a plain piece of glass can be employed in lieu of the etched.

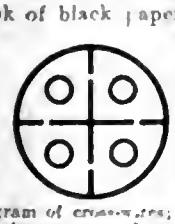

Fig. 6.—Enlarged diagram of cross-wires; the breaks in the lines and centres of dots are scraped away with a needle.

The Graduated Scale.

The graduated scale was constructed out of two 2d. wooden rules divided into inches and tenths, procurable anywhere. A paper band was stuck on throughout the combined length and the scale renumbered from 2 to 26 inches, as shown in fig. 4, with an index mark on a piece of white paper on the carrier above.

The scale can be accurately adjusted as follows:—With a carpenter's square and blade in contact with the pivot, rule a pencil line across the baseboard, and repeat the operation the other side of the pivot. Close to it make a pencil dot exactly midway between the drawn lines. Lay a steel rule down with any convenient division, say, 6 in., adjusted to the dot, and at the zero end of the rule bring a slip of card into contact, and temporarily secure it with two drawing-pins. Withdraw the rule and gently butt a set-square against the card, and bring the cross-wire carrier into contact with the set-square. If the index is now set to read 6 in. on the scale it will be accurately adjusted for all distances. With the two drawn lines as a guide, the position of the pivot can also be indicated on the edge of the baseboard, which will be found useful at times.

Making the Test.

The operation of the apparatus is exceedingly simple and quick. The lens is mounted on the V-supports, and the cross-wire carrier run up to its back and centered, the circles effecting this with ease. The cross-wire carrier is roughly set to the estimated focus of the lens under test, and the image of the cross-wires brought into the region of the illuminated hole by means of the mirror.

Should the node of the lens be other than over the axis of the pivot, swivelling the turntable will displace the image in amount dependent upon the distance between the two. If the direction of the image coincides with that of the turntable, the lens-carrier must be pushed towards the mirror; if in contrary direction, towards the cross-wires.

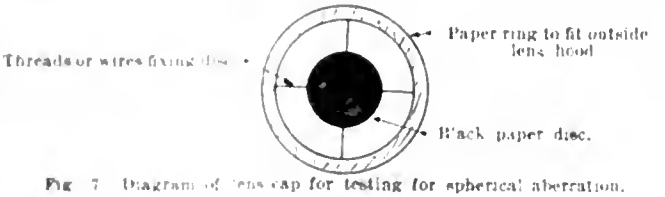

Fig. 7.—Diagram of lens cap for testing for spherical aberration.

In practice the lens-carrier is pushed well towards the cross-wires and gradually retreated until the movements of the image is reduced to small proportions. Frequent re-focussing at this stage is not required. Seeing that both carriers are parallel with the baseboard, the mirror is brought close up to the lens and adjusted so that the vertical cross-line and its reflected image are in the same straight line and almost overlapping. The image is sharply focussed, and the lens-carrier *gently and slowly* revolved through a moderate angle. When no displacement occurs final exact focussing is effected and the focal-length determined with exactitude. Dr. Clay says this may be done correctly within a few hundredths of an inch, but construction hardly admits of such precision; still it has been found that with well-corrected lenses measurements by different operators have agreed within 1/40th of an

inch, a degree of accuracy more than sufficient for all ordinary purposes.

With some objectives, such as portrait lenses, spurious images of the cross-wires may form, due to internal reflections, which come to a focus either behind or in front of the focal plane. Once recognised, they cannot be mistaken for the bright and sharply defined image afforded by the axial rays.

If spherical aberration is present in any degree the determination of the best average focus is a matter of some doubt. In such cases a medium stop should be employed.

Dr. Clay applied the apparatus to the measurement of the various errors existing in lenses, expressing their amounts by coefficients, but few will care to undertake this. Mostly, the presence or absence of aberrations can be determined in sufficient degree by inspection of the image on the focussing screen of a camera, but slight degradation of detail, due to want of aplanatism, is not so readily detected.

The well-known method of determining its presence or otherwise can be employed with the apparatus. Focus is respectively obtained with a medium stop, and with the special stop shown in fig. 7. If the readings coincide the lens is aplanatic; if not, spherical aberration is present.

VIVIAN JOBLING.
E. A. SALT.

CHATS TO A RECEPTIONIST.

FIRST of all, it is very desirable that your appearance should be smart and respectable, so that you can demand respect.

Showy dresses are against all business principles, black being the popular colour.

A successful assistant must have common sense and self-respect; it does not mean that you have to be a genius in order to use ordinary everyday common sense, yet common sense is the greatest money-maker in the market.

Always endeavour to be prompt at business, so that your employer will respect you. Remember, if you are late, he is entitled to an apology or an explanation, otherwise he will feel annoyed, though he may not show it.

There are only 60 minutes to an hour—no more. Forget private and home thoughts, and concentrate on the business and its welfare.

Relationship with Business.

Your position is a very important one—in fact, one of the main springs of the firm's clockwork, and on your ability rests to a great extent the success of the business. It is very essential that you should know all the business routine—in fact, as much as your employer knows about the salesmanship of photography. You are his mouthpiece; you are like the driver of a horse and vehicle, and hold the reins, can either let the horse wander its own way or direct it rightly, either let customers have what they ask for, or advise and lead them to something better.

You cannot expect your employer to look after *your* interests; you have got to rise or fall by your own personal efforts.

Fair Play for Both.

If your employer were not making a profit on your work, he would not be employing you. You will never be worth more money to yourself until you are worth more money to him. He is entitled to a fair profit on your services. He takes risks that you do not have to take. He supplies you with a place in which to work. He loses money when you make mistakes.

Be fair with him, as you expect him to be fair to you. The more money you can make for your employer, the more value you will have in his eyes. If you can show him that you are making more for him than his other employees, unless he is an idiot, he will pay you more.

Play as fair with your employer as you expect him to play fairly with you.

Manners.

Bad manners and treatment in the reception-room or shop often lead to a disappointing result. Assistants must always leave their tempers out of doors and must exercise the greatest power of self-control, remembering that soft words drive away wrath. When dealing with customers, try to listen to your own conversation, and consider if you think it sounds respectful and sympathetic.

Don't let people criticise you; criticise yourself. We are inclined to think that people have a warped judgment of our faults, whereas it is often ourselves.

One of the most important reasons why we must respect our patrons is because they provide for our daily bread.

To most people, having their photograph taken is a very distasteful occupation, and we cannot do too much to ameliorate their feelings.

Some people always expect many attentions, and are pleased to receive courtesies.

To be courteous shows good taste and is pleasing to all, but discretion and courteousness must go hand in hand. Sympathise with your clients and they will take your advice, especially those undecided. Begin well with a pleasant greeting; make them feel at home.

Get into the habit of sizing up your customers; try to read their character—at least, that part of their taste; try to imagine what they are likely to want and what suits them; it will require a certain amount of shrewdness, but it is easily acquired by practice. The bustling business man, the reserved old lady, the gushing maiden, and shy boy all require their various styles.

Customers object to a listless, apathetic assistant who makes no effort to realise the customers' wants.

Begin well; greet people with a smile and a pleasant expression; show an anxiety to serve them, and your success of a good order is assured.

Sitters expect a heap for their money—a smile of welcome tempered to an exact shade of deference, instantaneous attention, tireless courtesy, a vivid interest in their wants, all of which you can easily give them.

Most people think we run the show for their benefit, and we could not carry on without their patronage, which is quite true if we regard them as one of a thousand others thinking the same way.

Securing the Order.

Don't ram the prices down their throat.

Don't even mention the price, unless necessary, until the order is secured.

Always, where considered suitable, suggest the order to be one dozen, etc. Try to forget, or pretend, we don't do smaller amounts, unless circumstances require it.

It sometimes pays to be deaf to their inquiries. Climb down to the lower quantities or cheaper lines if the customer's position demands it. Don't rob them, but secure all you can; leave them with enough car money to get home with. Any fool can sell people what they want, but it takes a clever saleswoman to sell what they don't want.

Whether the style selected is a cheap one, or for a copy, always quote the extras inclusive, so that the customer is not aware of any extras

The reason why styles are published in 3's and 4's is to bring people in (otherwise the doorman), and then the firm relies on your skill and ability and make good on that. The better you know your business, the better your chance of success.

When a customer returns with proofs, always try to increase the order. This will benefit you as well as the firm; keep in your mind the various ideas of suggestive specialties which you can recommend for their consideration, enlargements, miniatures, etc., etc. A commission is given to encourage you to push these extras.

A knowledge of various technicalities is very useful when discussing complaints, or points of interest, such as how a negative is made, how and why it is retouched, the making of the print, etc.

Photographs Reproduced.

Bear in mind that photographs brought in to be reproduced or copied are generally of their *dear relatives*, and must be carefully handled, thoughtfully considered, and judiciously commended. If it is not exactly sharp and clear, don't say it will reproduce clearly, but that the best will be made of it, and that possibly in most cases it can be made to look better.

Delivery of Work.

Always be ready, if work is not complete, to express regret, and say you hope to have it ready in a few days. Don't give a definite time and commit yourself unless you know it will be ready. Always strive at keeping your customer in a good humour.

If we have a mount or frame that will suit the order in hand, make every effort to effect a sale; it is possible that every photograph taken will be framed eventually, and why shouldn't you sell that frame?

In some cases you might secure the order to have the photograph coloured.

If customers show disappointment in the results, use great tact and try to convince them otherwise, unless an improvement can be usefully applied. Be familiar with all prices. Knowledge, tact, and push must eventually lead to success. With good education, good disposition, and tact the receptionist could almost double an ordinary business as soon as she discovers the difference between opportunity and importunity.

The Reception Room.

Everything about the place should reflect order, thrift, cleanliness and system. Here all the honour (and profit) lies. There should be an atmosphere of cheerful refinement, and not that of a tuckshop.

All specimens to be kept in order and replaced when soiled, etc., or out of date; suggestions made for better appearance when conditions demand it.

J. F. SLACK.

HOW THE ROYAL WEDDING ABBEY PHOTOGRAPHS WERE TAKEN.

Some remarkable photographs were taken in Westminster Abbey on the occasion of the wedding of Princess Mary to Lord Lascelles, and in spite of the dim lighting which the Abbey affords the resulting pictures were as perfect as any studio or cinema producer could expect to secure.

Great difficulty had been experienced from the first in obtaining facilities and privileges to admit photographers to record this historic scene, but difficulties were at length overcome, and the Newspapers Proprietors' Association were able to appoint Mr G. Lymbery, of "Photopress," and Messrs. Neal and Console, of the "Daily Mail," to act as official photographers. It was also decided that the resulting negatives were to be pooled, so that one should cover the other in case of failure.

A special stand was erected in the Abbey, but not in a favourable position, because of a big chandelier carrying glaring lights coming almost over the heads of the Royal party. Fortunately, however, the backed plates used minimised halation. Imperial "Eclipse" and Ilford "Zenith" 650 H and D plates were chosen after exhaustive tests had been made, and the photographers nervously awaited the critical moment.

Immediately the bride with her Royal father arrived at the altar steps the photographers began exposing plates for all they were worth, and something like half a gross of plates in all were exposed on the subject. The light was extremely good, three seconds being the maximum exposure at *f*.4.5. The favourable light tempted Mr. Neal, who was using a Cooke-Aviar, to stop down to *f* 8, and give a longer exposure at a time in the ceremony when very little movement was happening, this produced a brilliant and well exposed negative, full of detail, which was the one from which prints were made for the general Press.

A special messenger service had been established, and the first batch of plates left the Abbey at 11.40, these plates were conveyed via Parliament Square to the House of Commons, where the Underground passage leading to Westminster Station was specially opened for the purpose, and at the other end of this passage further messengers were in readiness to convey the dark slides to Fleet Street. No time was lost in development, and prints were already on their way to the evening newspapers before the Abbey ceremony was finished, prints also being on the trains to provincial centres before the carriage conveying the couple had returned to Buckingham Palace. Aeroplanes were called into requisition to carry the photographs to Paris and Manchester. The results were a great achievement for British plates and lenses.

Photo-Mechanical Notes.

The Use of an Optical Enlarger to the Lithographer.

An optical enlarger is a necessary apparatus in a modern lithographic establishment where poster and large work is executed. One use to which it is employed is to obtain the key in chromelithography. This key enables the litho artist to place each colour in its correct position on the various stones used in the reproduction. The photographic method of obtaining the key is to photograph the original upon a plate which renders all detail. The intelligent use of panchromatic plates or film and filters is therefore essential in most cases. The negative obtained must be one that is not dense, but has the details in the colours well emphasised. This negative is enlarged to the required size upon a glossy bromide paper. Development and exposure of the bromide print must be so regulated that the result has no blacks in the shadows, but every detail must be well defined. It is generally advisable to dilute the developer with equal parts of water to obtain this effect. The enlargement, when dry, is passed on to the litho artist, who places a sheet of transparent tracing paper or gelatine over the image, and then proceeds to outline all the detail with a black transfer ink. It will now be seen that if the bromide print shows strong contrast it would be difficult for the artist to see and follow the detail. This outlining can be made upon the actual surface of the bromide print, and when finished is transferred to a litho stone in the usual way. Prints are made from this keystone upon a special paper, and then dusted with an offset powder which adheres to the ink image. This outline is laid on a damp litho stone and passed through the press, the result being a faint violet outline of the colours to be reproduced on the stone. This operation is repeated as many times as there are stones for the reproduction.

Another method is to make a small transparency from the negative, which is placed in the enlarger and projected to the required size on to a sheet of transfer paper. On this the artist outlines the detail. The Eastman Projection Printer is especially suited for this class of work, as it enables the artist to work in the accustomed position when drawing, which is not possible when using the ordinary form of enlarger. It is quite practical to make screen and grain negatives for poster work in this enlarger, the method of working being as follows: A small continuous tone negative is first made upon a small plate from the original. This negative must be of a good quality, and when dry, is placed in the holder of the enlarger and projected to a convenient size. No focussing is necessary when using a Kodak enlarger of this form, as the focussing is automatic and the image always sharp. Lay a process dry plate, which should have a backing of black or brown paper, upon the enlarging table, and over this plate bridge a half-tone screen, the ruling selected depending upon the size of the poster. The screen must be adjusted to a certain distance above the sensitive plate, which varies with the screen used. The following table will give the distance:

100 lines to the inch = 15 mm. distance.
120 lines to the inch = 12 mm. distance.
150 lines to the inch = 10 mm. distance.
170 lines to the inch = 8 mm. distance.

This screen distance can be maintained by supporting the screen on strips of wood cut to the above thickness. Fig. 1 shows an outline of the arrangement.

The stop to use for the shadow exposure is one having a diameter of 1/100 the distance of the lens from the sensitive plate, and that for the highlights 1/50. The exposure for the shadows is approximately 30 to 50 seconds, and that of the highlights 3 to 8 seconds, this being for an average negative. Develop for about 2 minutes at a temperature not lower than 65 deg. Fahr. in the usual hydroquinone-caustic. The result should be a screen positive, showing the high lights as small dots, or entire absence of the same, the middle tones as larger dots, the half-tones being joined together, and those

of the lowest almost overlapping or completely closed in. If the dots are too large they can be reduced by the usual methods, or if not dense enough be intensified, the silver cyanide intensifier being especially suited for the purpose. From this screen positive the enlarged screen negative is made to the size required on a well-drained wet-plate, which is laid on the enlarger table. Another method is to enlarge upon a sheet of Transferotype Bromide paper, and then transfer to a substratumed glass support. If a very large result is wanted two or three prints or even more can be joined together, the result being an enlarged screen negative, which is printed

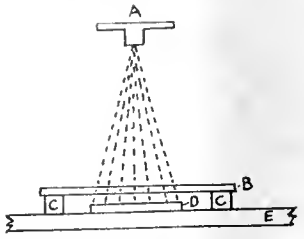

Fig. 1.—A. Lens of projector. B. Half-tone screen. C. Wood support for screen distance. D. Sensitive plate. E. Table of projector.

in the usual way either upon litho zinc, or if made for half-tone upon copper or zinc. To obtain a grain negative the positive is made by placing a metzograph screen of suitable grain in contact with the dry plate on which the positive is made, and exposing through a very small stop. It will be seen that by using this method there is no need to purchase large screens; one of moderate size is quite sufficient. The enlarger will also prove of great use when employed as an optical pantograph, and in many other ways supplies a long-felt want in the working of modern lithography.

W. J. Smith, F.R.P.S.

The following patents have been applied for:—

Cameras.—No. 5,602. Photographic cameras for process work. F. J. Connolly, Ltd., and F. H. Salisbury.

Intaglio Printing.—No. 5,566. Rotary intaglio or photogravure printing-machines. W. Gamble and A. W. Penrose & Co., Ltd.

Exhibitions.

MR. BANFIELD'S PICTURES AT THE CAMERA CLUB.

Mr. Banfield's exhibition at the Camera Club reveals him as a photographer with a keen landscape-sense. His taste is catholic. Some of the compositions are planned in the grand style and endowed with the magic of luminosity one experiences before a Claude or a Turner. Others, again, are quite modern in inception; one or two are suspiciously near being "beautiful facts." But even these have an idea in them; usually an idea of line-pattern. Perhaps the most forcible example of this variety of Mr. Banfield's work is his very queer "Towpath, Guildford," which seems to claim its place here on the strength of its great sweeping lines. But it is queerness alone, not beauty, upon which the thing sues for admiration.

Another work in which composition is obvious is "November Morning, Godalming." But this is not an aggressive design like the other; it is simply a well-behaved composition wherein everything falls happily; as everything likewise does in the highly-successful "Lincoln's Inn Fields."

From a long experience of photographic pictures I have come to believe that composition is the easiest part of the artistic equipment to acquire. The trick is quickly picked up, and once learned is never forgotten. But proper tone-relation is an accomplishment that comes much later and sometimes never. It is because these matters are so elusive that the average spectator, in such an exhibition as the present, cannot put his finger on faults; he only feels that something is not quite convincing. Thus the camera man escapes a good deal of censure in this department of artistic expression.

The works here are, with one exception, agreeably free from obvious wrong tone-relation; the exception being "Ludlow Castle," where the bridge forms a dividing line between two different keys of tone over the self-same objects. Almost every other picture offers some little solecism upon mature consideration; but in a general way, effects of light and atmosphere are rendered with an attractiveness above the common. Perhaps the finest result of this kind is seen in "Lincoln's Inn Fields," with its motive of sunbeams. In the rather anomalous "Piccadilly," what ought to have been a triumph of light-laden mist effect in an impressive scene is robbed of all naturalism by being in far too low a key—it is an impossible mixture of murky fog and slanting sunshine. However, as a piece of tone, considered apart from naturalism, it is delightful.

Most of the works are bromoils, and, as such, are highly accomplished works. They include a selection of heads and portraits which show originality of idea. The finest and most ambitious of these is certainly "Karsavina"—with its rich tones and sparkling accents. The pose and the face are both beautiful, although the left hand is unfortunate in its arrangement.

On the whole, the show is a display of sound technique and artistic feeling.

F. C. Tilney.

FORTHCOMING EXHIBITIONS.

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 14 to 16.—City of London and Cripplegate Photographic Society. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 15 to 26.—Welsh Salon of Photography. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 16 to 18.—Leytonstone and Wanstead Camera Club. Particulars from the Secretary, Charles Wormald, 1, Colworth Road, Leytonstone, London, E.11.

March 27 to April 8.—Dennistoun Amateur Photographic Association. Latest date for entries, March 14. Particulars from the Exhibition Secretary, Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 5 to 8.—Faversham Institute Photographic Society. Latest date for entries, March 31. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Mary Pickford's Camera Man.—A daily paper, speaking of Miss Mary Pickford, and her methods of producing pictures, says:—"Mary is very proud of her camera man, who is said to be the best man at his job in America. He is Charles Rosher, an Englishman, and he was with a well-known Bond Street firm of photographers before he took to moving-pictures."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications February 20 to 25:—

REFLEX CAMERA.—No. 4,917. Collapsible photographic reflex camera. B. Foulkes-Winks.

CAMERAS.—No. 5,554. Photographic cameras. F. L. Burger.

DRY-MOUNTING.—No. 5,506. Press for dry-mounting photographs, etc. P. J. Burrell and R. W. Homewood.

PRINTING FRAMES.—No. 5,316. Photo-printing frames. E. W. Davies.

TRIMMING-GUIDES.—No. 5,538. Trimming-guide for photographic printing-masks. E. B. Fry and E. B. Fry, Ltd.

PASSE-PARTOUT BINDINGS.—No. 5,539. Passe-partout edge bindings. E. B. Fry and E. B. Fry, Ltd.

PRINTING BOXES.—No. 5,540. Printing-boxes for photographic films. E. B. Fry, E. B. Fry, Ltd., and R. Sutton.

PROJECTION METHOD.—No. 5,601. Projection of photographic and photo-mechanical images. A. Hamburger.

VERTICAL ENLARGING.—No. 4,939. Vertical enlarging photographic apparatus. F. Overton.

SHUTTERS.—No. 5,397. Photographic shutters. F. A. G. Pirwitz and A. Wollensak.

PRINTING-MACHINES.—No. 5,650. Photographic printing machines. E. Sankey.

IMAGE TRANSFORMING METHOD.—No. 5,256. Method of transforming photographic silver images into tanned gelatine images. P. Schrott.

MOUNTING.—No. 5,163. Means for mounting photographs, etc. J. C. Suddards.

SENSITIVE PAPER.—No. 4,957. Photographically-sensitive paper. A. R. Trist.

PROJECTION SCREENS.—No. 5,084. Optical projection screens. A. Blaut.

CINEMATOGRAPHY.—No. 5,324. Apparatus for cinematographic photography. F. E. Cadett.

CINEMATOGRAPHS.—No. 5,407. Cinematographs. B. Gwozdz.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STEREOSCOPIC CINEMATOGRAPHY.—No. 173,833 (September 25, 1920). The two members of each stereoscopic pair of pictures are simultaneously superimposed on the screen, the pair following each other in the same rapid succession as is required in the projection of cinematograph film of normal width.

A cinematograph lantern may be used, having two internal sections fitted with twin lenses, with their centres spaced apart so as to coincide with the respective centres of the pairs of stereoscopic photographs on the film.

The extra-wide gate is constructed in two sections and hinged at the centre, each section corresponding to each member of a stereoscopic pair of photographs. The central hinge enables each section of the gate to assume the angular position for each member of a stereoscopic pair to be refracted in an oblique direction capable of bringing it on the same centre of the screen, i.e., each superposed on the other. Fig. 1 is a diagram of the gate in plan, and fig. 2 is a front elevation. In these diagrams D is the guide groove, D^1 is the gate frame, D^3 is the central hinge, D^4 is a slot in the thickness of the frame constituting the gate which allows the hinge to work so that the two halves of the gate may be inclined towards each other and thus produce the slight angle at the centre of the film above referred to, the natural elasticity of the film automatically restoring it to its flat condition as it leaves the gate and is wound on the receiving reel; K^2 are the axle of spring rollers (not shown in fig. 1) which are in adjustable contact with the film to minimise friction and generally regulate its motion in passing through the gate.

An illuminant and condenser are fitted for each half of the gate, and each set of these is mounted on a platform B B (fig. 3), to which is connected a corresponding section of the gate so that the latter can, by virtue of its central hinge, freely assume the angle necessary for the convergence of the two projected rays from the twin lenses without interference with the sprocket (shown on dotted lines at S^1, fig. 3) or the other mechanism of the projector. Fig. 3 is a diagram of the general arrangement as described. A A are the twin lenses, D^1 D^1 are the two

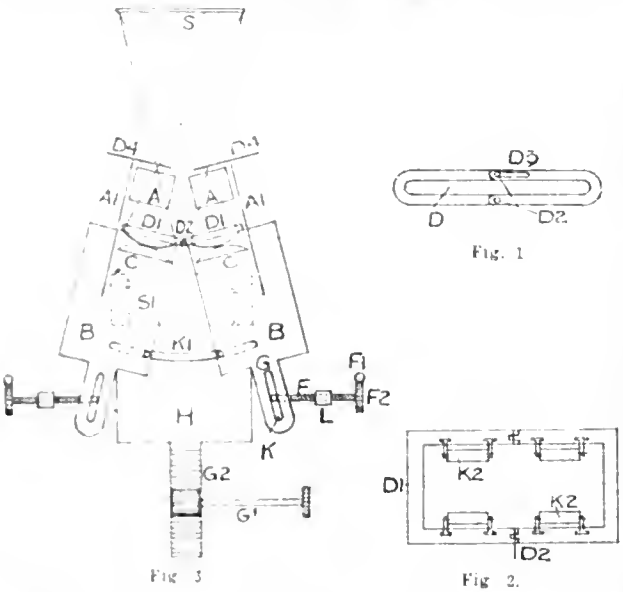

Fig. 3. Fig. 1. Fig. 2.

sections of the gate, D^3 being the hinge at the centre. A rotating shutter D^5 of the usual type to each lens is mounted on a shaft A^1 and is connected with the continuous moving mechanism which controls the Maltese cross, or "dog" movement of the sprocket, by suitable bevel gearing the teeth of which are of such an angle and depth as to allow a slight margin of play in order to give the small travel of the lenses towards each other which is required to produce convergence on the screen.

Fig. 3 shows on the rear of each platform B an extended bar or lug bearing a slot K in which works a stud on a loose collar at end of shaft F which has a screwed part working in a fixed nut L, F^1 and F^2 being a worm and worm-wheel respectively. This arrangement is designed to give a maximum of delicate adjustment of the twin lenses, combined with a locking effect in any position of the lenses which may be determined upon. The base H has a semi-circular slot K^1 and the platforms are connected movably thereto by pins taking into the slot; the platforms are also connected to the base by the pins of the central hinge of the gate continuing down and into a socket in the base. A rack and pinion movement, as shown at G^2 and G^1, enables the desired focus of the two halves of the images to be obtained on the screen S. The two sets of condensers are indicated at C C.

The screen S is a sheet of ground glass with the plain side nearest to the lenses. A mirror or other reflecting surface of

Fig. 4.

equal angular dimensions to those of the screen is placed behind it and above it at such a height (about equal to the depth of the screen) and at such an angle thereto as to collect the image from the ground glass screen and allow it to be seen easily by inspection from the front. Fig. 4 shows this arrangement, and L^1 is the lantern, S the ground glass screen, and M^1 the reflecting mirror. An alternative plan dispenses with the reflecting mirror:

the ground glass screen only is used with the ground side towards the lantern and the plain side backed with a rough, white surface such as white blotting paper. In this arrangement also the screen is to be viewed from the front, *viz.*, looking from the lantern The image on the ground glass screen itself (omitting the mirror) can also be viewed effectively directly at the back of the screen—*viz.*, looking towards the lantern.—Samuel Dickinson Williams, 8, Faulkner Road, Newport, Mon.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, MARCH 12.

United Stereoscopic Society. 1920 Competition Slides.

MONDAY, MARCH 13.

Bradford Phot. Soc. Members' Print Night.
Dewsbury Phot. Soc. "Wentbridge." W. E. Gundill.
Kidderminster P.S "Cornwall and the Lyonesse." F. W. Pilditch.
Nottingham P.S. "Fair Lusitania."
Southampton Camera Club. Ladies' Evening.
South London P.S. "Composition in Landscape." R. H. Lawton.
Wallasey A.P.S. "Through the Grecian Archipelago and Near East." W. Butcher & Sons.
Walthamstow P.S. "A Further Chat on Pictorial Composition' S. Brigden.

TUESDAY, MARCH 14.

R.P.S. Annual General Meeting.
Belfast C.P.A. Camera Club. "Art as Applied to Photography." S. Leighton.
Bournemouth C.C. Instructional Evening for Beginners. J. Thomas.
Cambridge Phot. Club. "Picture Making in Northern Italy." G. H. Dannatt.
City of London and Cripplegate P.S. "The Glory that was Rheims." E. W. Harvey Piper.
Exeter Camera Club. "Mespot and Persia." A. O. Rowden
Hackney P.S. "Lantern Manipulation." J. Williams.
Leeds Phototgraphic Society. Members' Lantern Evening.
Nelson Photographic Society. Members' Exhibition.
South Glasgow C.C. "Camps and Camping." Thos. Lochhead.
South Shields P.S. "Cloud Formation." John Heys
Stalybridge P.S. "The Hand Camera in Use." T. A. Greenall.

WEDNESDAY, MARCH 15.

Borough Poly. P.S. "Pictorial Work in Great Cities." A. H. Blake.
Catford Camera Club. "Colour Photography." W. E. Unwin.
City of London and Cripplegate P.S. "Ely Cathedral." H. W. Fincham.
Croydon Camera Club. "Southern Italy." W. Sanderson, J.P.
Dennistoun Amateur Phot. Assoc. Prize Slides.
Edinburgh P.S. "Bromoil Process." G. H. Hanlin.. And Lantern Slide Competition.
Forest Hill and Sydenham P.S. "Retouching."
Ilford P.S. "Simple Portraiture." C. R. Wormald.
Partick Camera Club. Third Lantern Slide Competition.
South Suburban P.S. "Bromide Enlarging." A. G. Buckham.

THURSDAY, MARCH 16.

Camera Club. "Portraiture in Colour." C. Pollard Crowther.
City of London and Cripplegate P.S. "Wonderlands of the Western World." J. Dudley Johnston.
Gateshead C.C. "Bromide Toning." J. T. Carnaby.
Letchworth C.C. Lecture. J. W. Swan.
Liverpool Amateur P.A. "In the Shires of the Sea Kings." Rev. S. R. Laundy
North Middlesex P.S. Visit to Bolt Court School of Engraving and *Daily Mirror* Offices.
Rochdale Amateur P.S. "Bromoil." F. Greenwood.
South Glasgow Camera Club. Whist Drive.
Tunbridge Wells Amateur P.S. "What to Take" and "What not to." H. Wild.
Welfare C.C. "Art in Relation to Photography." James Huck.
Wimbledon C.C. Lecturette Competition.

FRIDAY, MARCH 17.

R.P.S. Pictorial Group. Criticism of the Affiliation Competition Prints by J. Dudley Johnston (in conjunction with the Affiliation of Photographic Societies).
Wombwell P.S. Kodak Lecture.

SATURDAY, MARCH 18.

Leeds Camera Club. Exhibition of Members' Work.
Walthamstow P.S. Visit to a London Picture Gallery.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, March 7. The president, Dr. G. H. Rodman, in the chair.

The programme was arranged by the Scientific and Technical Group, and included the following subjects.

A paper was read by Mr. Howard Farmer on "Direct Photography." After pointing out that his method is a triumph over the ordinary negative method, which is a complete and absolute wash-out, Mr. Farmer informed his audience that he was not giving his secret away. Although the lecturer was listened to for an hour, during which he gave some delightful talk, and exhibited some excellent results achieved by himself, his hearers were left little or no wiser.

The next paper, by Mr. H. W. Lee, B.A., upon a "Chart for Finding the Depth of Focus with given Aperture and Distance of Object for any Photographic Lens," was read by Mr. F. Simeon. The gist of this communication will be found on another page, the paper having already been communicated to the "British Journal" by Mr. Lee.

Mr. H. Flower then read the third paper, one by Dr. W. E. Bradley, entitled "The Carbonisation of Bromides (a simplified Ozobrome Process)."

The sensitising solution is made up as follows :—Take, of a 5 per cent. solution : Potassium ferricyanide, 6 ozs. ; potassium bromide, 6 ozs. ; potassium bichromate, 4 ozs. ; water, 5 ozs.

The unsensitised tissue is immersed in this solution until limp. It is then drained and rinsed in clean, cold water, and transferred to a neutralising acid bath consisting of 1¼ oz. of a 10 per cent. solution of hydro-bromic acid in 80 ozs. of water for about 60 or 80 seconds. The tissue and bromide print are brought into contact under water, and after being squeegeed are put under pressure for about 30 minutes.

To carbonise the bromide picture direct, transfer the sandwich to warm water, as in carbon printing, and wash off the soluble pigment. On the other hand, to make a transfer place the sandwich in cold water, and separate the prints. Squeegee the carbon tissue to the transfer paper, and place under pressure for half an hour, and carry on the process as before and in hot water. The bromide print will be bleached and can be re-developed. Alum, citric acid, etc., are not required in this process. Good results are, of course, only obtained by using good bromide prints.

A hearty vote of thanks was accorded to the authors and readers of the papers in the usual way.

CROYDON CAMERA CLUB.

It has been the custom for Mr. F. Ackroyd once a year to favour the club with a lantern-lecture entitled "Travellers' Samples," and although the material sometimes has been slender, often a mere record of a short holiday, yet he always succeeds in interesting his audience with a combination of humour and wide general information

Nothing compels an accurate description of the quality of the slides usually produced, and the admiration induced by the cast-iron nerve required to show them in some subtle way eventually extended to the pictures on the screen. Possibly because they so consistently came up to expectation.

Last week "More Samples" provided a rude shock, primarily due to the misplaced zeal of the secretary, Mr. Sellors. Being possessed of a Sanger Shepherd density meter, he fatuously and foolishly lends it to Mr. Ackroyd, together with home-made slide-rules and photometric scales, and instructs him in their use. And with dire results, for gone, probably never to return, were all the dear old characteristics. Certainty replaced speculation as to what any particular slide was intended to represent, and in general quality the slides might have been the work of any ordinary skilled worker. They owed their origin to a tiny V.P. Kodak fitted with anastigmatic lens He made good with a highly interesting travel lecture, and was accorded a hearty vote of thanks.

THE SUPPLY OF RADIUM.—In a lecture on Radio-Activity, at the Royal Institution last Saturday, Sir Ernest Rutherford stated that the total amount of radium in existence at present was about 160 grammes. The commercial price was £20 per milligramme.

Commercial & Legal Intelligence.

LEGAL NOTE.—Notice is given, pursuant to Section 242 (5) of the Companies (Consolidation) Act, 1908, that the names of Sheffield's Studios, Ltd., and Photographic Art Development Co., Ltd., have been struck off the Register of Joint Stock Companies, and that the companies are dissolved.

NEW COMPANIES.

E. G. FILM PRODUCTIONS, LTD.—This private company was registered on March 1 with a capital of £1,000 in £1 shares. Objects: To carry on the business of photographers, opticians, manufacturers of and dealers in photographic apparatus, etc. The subscribers (each with one share) are: W. S. Blandford, Sarre House, East Finchley, N.2; E. W. E. Blandford, 227-8, Gresham House, E.C.2. The first directors are not named. Registered office: 227, Gresham House, E.C.2.

O. RUHL (1922), LTD., has been registered as a private company, with a nominal capital of £10,000 in £1 shares (5,000 8 per cent. cum. pref.), to carry on the business of manufacturers of and dealers in cameras, photographic materials and appliances, etc. The directors are: Friedrich Otto Ruhl, 50, Roxburgh Park, Harrow; Edgar Oscar Sommerfeld, Uplands Road, Hornsey. Solicitors: Albert M. Oppenheimer, 31, Queen Victoria Street, E.C. The registered office is at 15-17, Middle Street, Aldersgate, E.C.1. File number 180,054.

News and Notes.

"THE CLUB PHOTOGRAPHER."—The editorial offices of this well-known monthly have been removed to 81, Dale Street, Liverpool, to which address all communications should now be sent.

"THE PHOTOGRAPHIC JOURNAL."—The advertisement department of the Royal Photographic Society's "Journal" has been transferred from 63, Ludgate Hill, E.C.4, to the Society's house, 35, Russell Square, W.C.1.

CARBRO DEMONSTRATIONS.—A series of half-hourly demonstrations of the Carbro process will be given at the offices of the Autotype Company (74, New Oxford Street, London, W.C.1.) between 3 and 5 o'clock on the afternoons of Thursdays, the 16th and 30th inst.

THE NEW PRESIDENT of the Royal Photographic Society will be Mr. W. L. F. Wastell, whose name stands alone (under the heading of President) on the balloting paper. Mr. Wastell, who is now one of the Society's Vice-Presidents, has been an active and popular member of the Council for many years.

FALLOWFIELD'S CLEARANCE SALE of surplus stock commences on Monday, 20th inst. Many bargains in all types of cameras, lenses, enlarging apparatus, etc., will be obtainable, and a special sale list will be sent free to any of our readers who write for it; address, Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.2.

ROYAL INSTITUTION.—On Thursday next, March 16, at 3 o'clock, Dr. P. Chalmers Mitchell begins a course of two lectures at the Royal Institution on "The Cinema as a Zoological Method." The Friday Evening Discourse on March 17 will be delivered by Professor A. P. Laurie on "The Pigments and Mediums of Old Masters," and on March 24 by Professor F. G. Donnan on "Auxiliary International Languages."

NEW ZEALAND CUSTOMS TARIFF.—The revised customs tariff of New Zealand contains many items of photographic interest. A preferential rate is accorded to goods produced or manufactured in any part of the British Dominions, including British Protectorates. Under this British Preferential Tariff photographic chemicals are dutiable 20 per cent. ad val.; lenses, unmounted and without attachments, free; cameras, free; camera covers, and cases, 20 per cent. ad val.; sensitised surfaces and albumenised paper, free; albums, cinematograph films, and other photographic goods, 20 per cent. ad. val.

AERIAL PHOTOGRAPHY. We learn from an American contemporary that aerial photography has been developed by the army air service to a point where the 3,026,789 square miles comprising the continental United States could be photographed in a comparatively short time. Secretary Weeks, of the War Department, announced recently that one airplane had succeeded in making a composite picture of 150 square miles of land in nine days. With the use of other machines, equipped with devices developed by the air service, he said it would be a simple task to picture the United States as a whole. An interesting feature of the work, he added, was the fact that the pictures were made by photographers flying at a speed of from 125 to 150 miles an hour.

THE FIRST PORTRAIT. A writer in the "Daily Chronicle" states that the first photograph of a living person was that of an Englishman, a well-known civil engineer named Shanks, who, while visiting Daguerre, in Paris, in 1839, suggested to the inventor the possibility of portraiture by means of his process. Daguerre thereupon experimented on Mr. Shanks, and produced the first portrait after the subject had sat still for an hour in full sunshine. Shortly afterwards Daguerre came to England as a guest of the late Lord Avebury's father, and took his first English portrait—a picture of the future peer, then a child of five.

GLASGOW AND WEST OF SCOTLAND SOCIETY OF PROFESSIONAL PHOTOGRAPHERS. The monthly meeting of this Society was held on February 24. Mr. J. R. Brinkley, President of the Society, occupied the chair. The evening was devoted to the discussion of difficulties arising in the course of professional work generally, particularly in the everyday work of the studio. It was open to members to raise any points which they considered to be of interest. The subjects discussed covered a very wide field, and included such divergent topics as professional charges, the preparation of income-tax returns, and dull trade. A committee was appointed to co-operate with the Edinburgh Society in the arrangements for a suggested Scottish Congress to be held in Edinburgh in 1923.

ROYAL WEDDING PHOTOGRAPHS FOR THE U.S.A.—On board the White Star liner "Olympic," which left Southampton for New York on the day after the Royal wedding, was a small barrel, the contents of which were eagerly awaited on the other side of the Atlantic. Specially constructed to float, this cask was packed with films and photographs of the wedding. Off Nantucket the barrel was flung overboard, and picked up by a U.S.A. destroyer, which met the "Olympic" there. The destroyer then made for Boston, and from there the films and photographs were distributed throughout America. By this scheme the cinemas and illustrated Press on the other side were able to present pictures of the ceremony and street scenes a day earlier than would have been possible otherwise.

THE SLUMP IN POSTCARDS. How dearer postage is damaging the hitherto lucrative business of mail carrying is shown in an official statement issued by the Post Office last week. Compared with the year 1920-21 there has been the following falling-off:—Letters, 110,000,000; postcards, 77,000,000; printed papers, 190,000,000; newspapers, 12,000,000. The returns on which these figures are based, however, do not distinguish between picture postcards and other postcards. Compared with 1913-14, before the abolition of the "penny post" and the halfpenny postcard, the falling-off during the present year is estimated at:—Letters, 127,800,000; postcards, 420,500,000; printed papers, 22,300,000; newspapers, 17,100,000. In raising the rates last year the Post Office allowed for a certain falling-off in traffic, but their estimate of an increased yield of £2,500,000 has fallen short by £600,000.

THE METRIC SYSTEM BY EASY STAGES.—With the object of accelerating the introduction of the international metric system, the Decimal Association recommends gradual modification of the existing Imperial system of weights and measures. For instance, it is proposed that the existing table of avoirdupois weights would be greatly simplified, and that closer co-ordination with the metric system would be secured by the present adoption of the following interim table:—7,000 new grains = 1 metric lb.; 16 new drachms = 1 new oz.; 16 new ounces = 1 metric lb.; 2,000 metric lbs. = 1 metric ton. The metric lb. and its parts would weigh about 10 per cent. more than the Imperial lb., and 2 such metric lb. would be exactly equal to 1 kilogram. The suggested abandonment of all the present confusing intermediate denominations of weight between the lb. and the ton simply follow the practice already successfully established in the United States of America and also in some of the British Colonies.

FLEET PHOTOGRAPHIC BRANCH.—The creation of "Fleet photographic officer" and "sloop photographic officer" for the Atlantic and Mediterranean Fleets was announced in "The Times" on January 27, 1920, and officers have since been selected for these appointments. Information is now given in Fleet Orders as to the qualifications for candidates in the photographic branch. Naval ratings and Marines are both eligible. They must have previous experience in photography. Candidates must be recommended by their commanding officers as competent photographers, and must hold no higher non-substantive rating than gunlayer, 2nd class, at the date of application. In the Atlantic and Mediterranean Fleets examinations will be held every six months by the photographic officers, and on other stations names of candidates will be sent home to the captain of the "Excellent," who will arrange for their examinations and will nominate men to fill vacancies as they occur. It is particularly noted that previous experience should include Fleet work, such as triangulation of fall of shot.

DENNISTOUN AMATEUR PHOTOGRAPHIC ASSOCIATION.—The annual general meeting was held in the Club Rooms on the 1st inst. The secretary submitted a very full report of the year's work of the Club, dealing with the enthusiasm of the members, referring to the improved working facilities, and especially to the splendid work of the Rooms Committee, who have been untiring in their efforts to keep the rooms in perfect order for the comfort and well-being of the members. Both the secretary's and the treasurer's report showed the Club to be in a very satisfactory financial condition. On the motion of the retiring president it was agreed that the valuable services rendered to the Club by the hon. secretary be recognised in a tangible form. The principal officers for the coming year are:—President, Mr. James Reid; Vice-President, Mr. A. Robertson; Hon. Secretary, Mr. John Macdonald; Hon. Treasurer, Mr. Wm. F. MacPherson; Librarian, Mr. Wm. Johnston; Lanternist, Mr. A. Shepherd; Exhibition Secretary, Mr. C. Graham.

A NEWSPAPER PRINTED BY A PHOTO-OFFSET PROCESS.—The "Blackpool Times," printed by Messrs. J. Robertson & Co., Ltd., of St. Anne's-on-Sea, was referred to in these columns recently in connection with the printing of the paper by a photo-offset process, which has not previously been done in this country. Two further developments have now taken place which deserve to be recorded. The wedding of Princess Mary was made the occasion for printing in the issue of February 28 two full page illustrations in colour, by a photo-offset process, of the bride and bridegroom. The result is excellent for newspaper work, especially as this is the first time such a thing has been attempted, and no doubt next time colour work is printed a great improvement in the colour rendering will be possible. The illustrations are on the two centre pages, and are bound together by a border across the pages without any joining up. Apparently, three colours and a grey have been used. The issue of March 3 contained a full two-page illustration in black of the wedding ceremony at Westminster Abbey, and the result is eminently satisfactory.

JEFFERY & BOARDER.—A new joining of forces among the firms undertaking photographic and artistic service for photographers has come into operation on the first of the present month in the re-establishment of the firm formerly well known as Jeffery & McLeod as Jeffery & Boarder. Mr. Jeffery, who is fortunate in having had a very wide experience in all branches of photographic work, and who established the present firm more than twenty years ago, makes himself personally responsible for the production of every enlargement or print, and brings to this work the knowledge of many years in the making of the highest grades of bromide and carbon enlargements. Mr. Boarder, an exhibitor at the Royal Academy and formerly the chief artist for Messrs. Illingworth & Co. at Willesden, takes charge of the artists' department, contributing to this side of the business his own skill and taste as a draughtsman, colourist and miniature painter both executively and in the supervision of the firm's staff of artists. We were very interested in recently having the opportunity of examining a large collection of the firm's latest styles in monochrome and coloured enlargements. It would take too long to attempt to describe these in detail, but we may refer in particular to the series to which the title "Dorothy" has been applied. These are enlargements in monochrome, semi-tint, or water-colours, ranging in size from 13½ by 10 inches to 21 by 13 inches, and produced with a die-sunk impression of rectangular, circle, or oval shape, which greatly adds to their distinctive qualities. These enlargements are priced from 30s. down to figures which seem to us astonishingly moderate. The styles are specially designed for portraits of women or children, full length or head and shoulders, taken against light backgrounds. We could not but admire the very high standard of the colouring, and especially noticed the technique of the artists' work in dealing with the dresses of full-length portraits. Choosing only from this series of specimens, any photographer can provide his window at relatively small expense with a display of work which, we venture to think, would inevitably attract a great deal of custom to his studio. We were not surprised to find that Messrs. Jeffery & Boarder constantly receive the thanks of leading London and provincial portrait photographers for the care and skill with which commissions have been carried out. Another most artistic style of enlargement, in crayon and water-colour, is the "Lancaster," also for light background portraits and supplied at the price of 25s. It must not be thought, however, that work in a colour or monochrome finish is exclusively the specialty of the firm. Mr. Jeffery's department sets great store by its work in pure photographic enlarging, and in particular by the remarkable richness of its sepia toned prints and enlargements. Sepia toning has been a special study of the firm from the early days of this process, and certainly the specimens that we saw exhibit the process at its best. We can cordially recommend the newly re-organised firm to those requiring really high-class work.

PHOTOGRAPHERS IN JAVA.

To the Editors.

Gentlemen,—You may be interested to learn that photography as a hobby has during the last few years become extremely popular in this country. Amateur workers are now to be met with in all parts of Java and in the big cities, such as Soerabaia, Batavia, Semarang, Bandoeng and Djocjacarta, the professional photographers themselves do well with their amateur developing and printing departments.

The photographic trade of Java, however, is in the hands of American and German manufacturers. Their goods found their way into this island very soon after the cessation of the war, and an amateur with a British-made camera is very rarely met with.

I have been a traveller in the photographic trade for the past three years, and so far I do not know of any British firm having either a branch or a specially appointed agent to push their goods here.

According to the last census (November, 1920) Java has a population of over 35,000,000, and if the British firms in photographic industry will place their goods in this country I have no doubt that they will find a ready market.—Yours faithfully,

T. H. TAN.

C/o Hotel Sing An Kie, Soerabaia, Java, January 28, 1922.

LEUCO-BASES IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—On p. 16 of the "B.J." of January 13 M. Clerc briefly describes as a "New Process of Colour Photography" (F. P. 524,143, 1919, L. Didier) the use of the leuco compounds of certain dyes.

It would be interesting if your valued correspondent would point out the particular novelty in this process, and wherein it differs from the pinachromy process of Meister, Lucins and Brüning (D. R. P. 160.772, 1904; E. P. 4,994, 1904; "B.J.," 1904, Vol. 51, 886, 908: abst. 1905, 73).

M. Didier would use an autochrome negative, thus making use of the principle discovered by O. Gros (Zeits. f. phys. Chem., 1901, 57), that the leuco-bases are specially acted upon by those rays complementary to the colour of the dyes formed.

In the pinachromy process the patentees describe the production of separate constituent images with subsequent superposition, and the production of the one image on a single support, the use of an insulating coat and superposition of the succeeding images in a similar manner. Nitro-cellulose was chosen as the vehicle, as it furnished NO or NO_2. Nitroglycerine, nitrosamine, urea, citric acid, turpentine, anethol, and quinolin are also indicated as sensitisers. Leuco-setocyanin was suggested for the blue image, leuco-rhodamin for the red, and leuco-flavinilin for the yellow. Fixation could be effected with hydrochloric acid plus the sulphocyanides, or monochloracetic or other acids, alum, tartar emetic, benzol, or chloroform, etc.

E. König ("Photochemie," 1906, 60) says:—"Die Pinachromie hat keine praktische Bedeutung erlangt, da die Leukobasen meist zu wenig beständig, die erhaltenen Bilder nicht genügend lichtecht sind. Immerhin ist dieses Verfahren von grossem Interesse, weil es das einzige ist, welches photographische Bilder in verschiedensten Farben durch direkte Beleuchtung herzustellen gestattet." Or, "Pinachromy has no practical importance, since the leuco-bases are generally too unstable, the images obtained are not sufficiently fast to light. Nevertheless, this process is of considerable interest because it is the only one which enables photographic pictures to be prepared direct in the most varied colours."

The process was withdrawn from the market because of the instability of the results.—Yours faithfully. E. J. Wall.

Wollaston, Mass.

ROTARY PRINT-DRYING MACHINES.

To the Editors.

Gentlemen,—We have had our notice drawn to your issue of December 2, wherein you describe and illustrate a rapid print dryer. It is there stated that as far as your knowledge extends print drying machines hitherto on the market are of American manufacture. May we be allowed to draw your attention to the fact that our "Ensign" rotary print drying machine was the first entirely British-made machine, and has been used most satisfactorily for several years.—Yours faithfully,

Houghtons, Ltd.,
A. Catford, Publicity Manager.

February 28.

PRESS PHOTOGRAPHY.

To the Editors.

Gentlemen,—Having a keen interest in Press photography and journalism, and an experience of some 20 years and more in Fleet Street, the quotation you give from "The Journalist" on page 119 of last week's "B.J." calls for some comment.

One is rather surprised at the language used, especially when the writer claims that etiquette (with education) is part of the equipment of Press photographers. The writer is evidently lacking in this, as his expression, "hordes of young duds," etc., is, undoubtedly, devoid of polish and can only be classed as vulgarism. In any case, it is what one would expect to hear at a street-corner meeting and not in the columns of "The Journalist." Now, my experience is that there are plenty of Press photographers in Fleet Street who are well educated and fully equipped with their share of etiquette, and among these a good few juniors.

As one who is keenly interested in Trade Unionism, not sectional but universal, it is very hard exactly to find out what the writer is actually driving at. What does he really want? Has he got the support of the whole of his fellow members? Surely not. It strikes one that he is just a bothead with a sudden spasm of revolt. He tells us the top minimum for Press photographers is £8 8s., and at present there are a goodly number getting this wage. What is wrong, then? We assume some do not get this wage. Has he asked himself the question, "Are they worth it?" We cannot expect any man who has a sense of justice to expect top fees for men that are not competent. The statement that fully-trained men are expected to show a turnover of £120 per month, if correct, proves that things must be booming in Fleet Street, as one can number a good few of the competent sort.

Now, as to the "work-shy" men in Fleet Street—and by the phrasing one is led to assume it means the proprietors. I know most of these gentlemen, and fail to placate one who tallies with this description. Taking the staffs of the agencies all round, workers and principals, I have found most of them keen, alert, and always ready to keep up the status of the profession of Press photography. Of course, there is always one or two exceptions, and I am sorry to say they have been among the workers.

Re the "fifty-fifty" plaint, let me state at once that there are members of the National Union of Journalists who have been glad to avail themselves of working this system when they have been temporarily out of employment, and not new comers to Fleet Street by a long way. No doubt they would again be glad of the opportunity if necessary.

By all means let the Press photographers close up their ranks, but let them be level headed, and state clearly what really are their objects in view.—Your faithfully, "A Worker"

THREE COLOUR CAMERAS.

To the Editors.

Gentlemen,—I should be glad if you would give publicity in your columns to the enclosed copy of letter I have to-day addressed to the editor of the book, entitled "Byepaths of Colour Photography." I think this will cover some of the points raised by Commander Rendall in his review of this publication in to-day's "Colour Supplement" of the "British Journal of Photography."—Faithfully yours,

Aron Hamburger

51, Warwick Street, Regent Street, London, W.1, March 3.

March 3, 1922

Wm. Gamble, Esq.,

Editor, "Byepaths of Colour Photography."

Dear Sir,—I must protest against the further circulation of sundry statements made by the author of the booklet entitled "Byepaths of Colour Photography," as they are calculated to damage me and my associates.

For instance, on p. 33, the author permits himself to remark with reference to compensating devices for colour filters, the following: "The English patent 3872-13 is for 'ether pressure' device' granted to the Dover Street Studios, no application being made for same in the States."

No patent of such number, date and authorship has ever existed. Perhaps the compiler of this extraordinary work refers to British patent in the joint names of Prof. A. E. Conrady and myself, No. 28,722, 1912, to patent No. 1,140,576 granted in 1913 by the United States Patent Office, and the same patent granted at about the same time in Germany, France, Belgium, Switzerland, etc.

Again, on p. 34 the author's comment on the Hamburger-Coston patent of 1903 (for obtaining distorted photographic images) displays truly amazing acumen.

Permit me to inform you that this patent referred merely to a method of preparing photographic prints on fabric, of humans, and other animals, which when stuffed with a suitable stuffing would become available for use by children for rag dolls.

As there was no other or hidden meaning in the specifications than this, I cannot conjecture why it is dragged into what purports to be a dissertation on colour photography.

Furthermore, I find this book "stuffed" with other irresponsible and inaccurate statements.

Page 38, for instance, talks of a "curious but scientifically correct self-compensating action," etc., patented by O. Pfenninger.

Had not the book gone on to say "it is interesting to know that this is the camera which Dover Street Studios used in 1911-13 in taking successfully by instantaneous exposures three correct colour negatives, etc.," and had he not described a Polychromide printing process which I, the inventor of the Polychromide process, cannot recognise as anything like work of mine, I could have passed over the description of the Pfenninger camera without comment. The facts are as follows: When the Dover Street Studios were under my control we spent time and a considerable amount of money in many utterly fruitless attempts to take photographs in natural colours with O. Pfenninger's soi-disant colour camera. Before we discarded it, it certainly proved to be "curious, even

if we could not see visible evidence of scientific correctness" in any of its performances.

It is, therefore, indeed interesting to know that this is the camera which Dover Street Studios used in 1911-13.

As it certainly is not the camera used at the Dover Street Studios, where the Hamburger-Conrady instrument (which I still use) made every photograph in colour on paper which was ever shown by the Dover Street Studios, this statement might be accepted seriously by readers of the booklet who do not know Mr. Pfenninger and his camera.

I must, therefore, request that a correction of this and of the other inaccuracies previously pointed out to you, be attached to such copies of this volume as may be further offered for sale, and also, as far as possible, sent to previous purchasers..—I beg to remain, faithfully yours,

ARON HAMBURGER.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

M. G.—As you state that an improvement in covering power resulted from turning the lens round we must accept it as a fact which is, however, very difficult to explain. It might be due to a loose glass falling into position when the tube was turned, or to some want of accuracy in the camera which was corrected unknowingly in the process.

W. G. R.—Small plaques can be made from ordinary negatives by sensitising a thick film of gelatine with bichromate of potash, printing in the ordinary way and swelling the gelatine until the maximum relief is obtained. A plaster mould is made from the wet gelatine, and in this a plaster or metal plaque may be cast. So far the results obtained have had no commercial value, only profiles being at all satisfactory.

S. G. E.—It would seem to us that you can easily ascertain whether you have enough light for your purpose by the simple process of taking a negative. From our own experience we should imagine that at least double the candle-power would be necessary to give a properly exposed negative in one-tenth second. You do not mention diffusers or reflectors; these, of course, would have an important effect upon time of exposure.

S. J. A.—"The Air-Brush in Photography," by G. F. Stine, is published by the Abel Publishing Co., 421, Caxton Building, Cleveland, Ohio, U.S.A. We do not think the other book to which you refer is published in English, but No. 181 of the "Photo-Miniature" is devoted to "Air-Brush Technique," and if still in print can be obtained from Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, price 1s. 8d.

W. R.—Nothing is better to soften the light than starch made as for mounting with a little whiting mixed in. This is laid on thinly and stippled with a dry brush till even. The thin tracing paper, called papier mineral or waxed paper, as used for wrapping plates and paper, will answer the purpose well. Use casement cloth for dark curtains and nainsook or madapolam for the white ones. For roller blinds you must use the proper blind holland in suitable colours.

S. J. P.—So far as we know, materials for making bas-relief photographs are not on the market, nor have instructions been published outside of the many now somewhat old patent specifications for the production of this effect. As you say, most of these processes consist in taking a print on a pure, strong paper, such as platinotype, and pressing it from the back either with a blunt tool by hand, or by making some kind of die in lead or plaster of Paris, the pressed-out print being afterwards filled up from the back with a plastic mixture so as to cause it to retain its shape.

B. F. E.—Practically every operator has his own ideas as to spot lighting, but, as a general rule, it is obtained by placing a small arc or a 500-c.p. half-watt lamp fitted on a suitable shade where it will produce the desired effect, the lamp itself being, of course, concealed. You can get a lamp ready fitted up from Marion and Co. In the U.S.A. a half-watt lamp is often used fitted into a metal box with a condenser, like the ordinary limelight box on the stage, but much smaller. This enables a beam of light to be thrown in any direction from some distance. Little can be done with daylight, although an ordinary mirror can sometimes be used effectively to produce a small, bright light.

A. W. S.—If your inclinations are to the artistic rather than to the scientific aspect of photography, there seems no reason why you should not succeed as a portraitist. At your age it is not likely that any photographer would take you as a pupil. Probably your best plan would be to get in touch with the Polytechnic School of Photography, Regent Street, London, W.1, where you could receive a thorough training in every detail of professional work. It is just possible that you could obtain a grant in aid of your training from the Government. There was a scheme known as O.13, under which a number of ex-officers have been trained there. The complete course is 39 weeks, daily from 10 to 4.

A. G. W.—The arrangement used for photograph No. 2 is quite correct. That in No. 1 is wrong, as you are too far from the light, and the lighting is necessarily flat. There are many points at which you could place the sitter between position 2 and the window, and also many positions for the camera. In such a room you could get good fancy lighting and Rembrandt effects by placing the sitter so that the profile or narrow side of the face is illuminated directly, and the shadow side by a reflector. If you instal half-watt lamps, three of 1,000 c.p., fixed just above the window, about 2 ft. into the room, would be useful. These could be used with daylight for full lengths, or lowered to about 6 ft. for sitting figures at night.

M. W.—You seem to have acted in a very unbusinesslike way in refusing to send proof. It is an arguable point whether the customer is justified in cancelling the order because you refused to send him proof but insisted on his coming to your premises to see the proof. Although the point is a little doubtful, we are inclined to think that a County Court Judge would very likely say that the customer was perfectly justified in cancelling the order in view of such an unreasonable attitude on your part. However, that is somewhat beside the mark. Having received the order and accepted it from the customer, you have no right whatever to print post-cards for yourself, whilst, on the other hand, the customer has every right to have the photograph copied, sell copies to his pupils—in fact, to do just what he likes with them. Your remedy is to sue him for the amount of the order, but we are afraid that, in view of the peculiar policy you have thought it fit to follow, you stand a poor chance of getting ordinary justice.

JOURNAL OF PHOTOGRAPHY.

No. 3228. Vol. LXIX. FRIDAY, MARCH 17, 1922. Price Fourpence.

Contents.

SUMMARY.

Blocking out can be protected against scraping by covering with thin gummed paper or varnishing. This is but one of the many useful hints given by a contributor, who deals fully with the subject of blocking-out negatives in a practical article on page 151.

In a leading article we discuss the use of various reducers for remedying over-printed bromides, and describe the method of using the most satisfactory of them. (P. 150.)

Dr. B. T. J. Glover's valuable contribution on the contrast rating of bromide and gaslight papers, which attracted so much attention at a recent meeting of the Royal Photographic Society, will be found on page 156.

One of the many problems assigned to the photographic department of the Eastman Kodak Company's Research Laboratory is the working out and testing developing formulæ. Some methods of testing adopted by the Laboratory are given in a communication from the company on page 153.

Users of tanks for the development of the ultra-rapid grades of plates now coming into general use would do well to bear in mind that such plates need longer development (or stronger tank developing solutions) than the slower varieties. (P. 150.)

Mr. W. L. F. Wastell was duly elected President of the Royal Photographic Society on Tuesday last. A brief report of the annual meeting, with the names of the newly elected Vice-Presidents and Council, and a portrait of the new President, will be found on page 160.

The Council of the Professional Photographers' Association report a very successful year of working. The new members number 126, and there have been few resignations. (P. 159.)

The death is announced of Mr. Alexander Cowan, once a well-known worker in the world of photographic chemistry, and for many years connected with the house of Messrs. Marion. (P. 159.)

Ladder tripods are not used in this country to the extent their usefulness deserves. A very simple and portable pattern, devised by an American worker, is described on page 150.

Professor R. Namias, of Milan, recommends a method of intensification designed to produce a degree of density much greater than is commonly required. (P. 149.)

The South London Photographic Society have revived their "annual" exhibition after an interval of eight years. (P. 161.)

Mr. Marcus Adams and Mr. A. C. Banfield, both professional photographers, are two of the six new members elected to the Council of the Royal Photographic Society. (P. 163.)

EX CATHEDRA.

Dr. Rodman. While making, as we do on another page, a but little-needed introduction of Mr. Wastell as the newly-elected president of the Royal Photographic Society, we must take the opportunity of paying a tribute to his predecessor who retires after two years of undivided service. Among his many qualities, Dr. Rodman has that of optimism. Like Mr. Arnold Bennett's "card," he is "identified with the great cause of cheering us all up." This gift has been liberally bestowed in the public and private meetings of the Society, and has certainly been effective in dispelling what Mr. Wratten once called the "cathedral atmosphere" of the Royal. Moreover, to the conduct of the Society's affairs Dr. Rodman has applied a constant and tireless energy, witnessed, for example, in the consecutive series of house exhibitions, in the linking of the Society with allied Associations, no less than in minor matters of furnishing and equipment. He has, in short, got many things of advantage to the members accomplished by his individual effort and undeniable solicitation. The vociferous character of the vote of thanks at Tuesday's annual meeting did not unduly emphasize the appreciation of these labours and the personal esteem which Dr. Rodman carries with him on his laying down the cares of office.

* * *

Extreme Intensification Professor R. Namias has recommended a process of intensification suitable for the utmost degree of intensification and contrast such as is required in rendering visible traces of impressions obtained in the photography of suspected documents. The negative is first bleached in a bath of two parts potass permanganate and 20 parts hydrochloric acid in 1,000 parts of water, rinsed and developed in ordinary M.Q. The object of this treatment is to yield an image specially susceptible to intensification. The negative is then bleached in the usual bath of mercury bichloride and darkened with a developer. Next follows treatment with a bath of mercuric iodide compounded from two stock solutions:—(a) Mercury bichloride, 3 parts; hydrochloric acid, 1 part; water, 100 parts; and (b) potass iodide 5 parts; water, 100 parts. Solution (b) is added little by little to solution (a). A red deposit of mercuric iodide is first formed, the addition of (b) being continued until the mixture just becomes clear. On treating the negative, which has been intensified with mercury and well washed in this mixture, the progress of further intensification can be followed by transmitted light. The action of the bath is stopped as soon as it is seen that no further increase in density is taking place. If a still greater degree of intensification is desired, the negative may be subjected twice in succession to the treatment with the plain mercury bleach and re-development, but once the plate has been acted on by the mercury iodide mixture it is not susceptible to further chemical treat-

ment. It may reasonably be thought that it has not done so badly as intensifiers go, in this respect; but Professor Namias explains that the process is designed for a degree of intensification greater than is commonly required. Moreover, as the intensified image is a brown colour, still further contrast may be obtained from the negative by printing it through a violet screen such as may be made by soaking a fixed and washed plate in 1 per cent. methyl blue solution.

* * *

Wasted Retouching. The modern practice of sub-dividing labour in the production of portrait work often causes a serious waste of time, by reason of the workers in one department not understanding the requirements of those in another. Nowhere is this so apparent as in retouching, the retoucher, who has usually learned no other branch of the craft, having little idea as to the printing value of his, or her, work. This can be remedied to a great extent by taking a rough proof of the negative, and judging from it what retouching is really necessary, instead of working up to a uniform standard of smoothness. We have noticed that single-handed workers who carry the whole production through put very much less work upon their negatives than is found upon those retouched in the ordinary way. It is not suggested that it would be necessary to continue the practice of working from proofs after the retoucher was trained to see what was really necessary. There is, of course, the natural instinct of self-preservation on the part of the retoucher to be considered, but, as a rule, the time saved could be usefully employed in other ways, so that no immediate reduction of staff would be necessary. Another point worth considering is that the loss of likeness, so often due to over-touching, is practically eliminated.

* * *

Ladder Tripods. There are few outdoor photographers who have not felt the necessity for a very high tripod stand, by which they would be enabled to clear the top of foreground objects, such as walls, garden hedges, and the like, or to get more comprehensive views of factories and church interiors. So far, the only arrangement available has been made on the model of a pair of household steps, and this is too heavy to be transported, except by a special vehicle. An American photographer has devised a much more portable and simple stand, which many of our readers might be glad to copy. It consists of a tripod between seven and eight feet in height, of which the back leg is a light ladder, the other two being of the ordinary pattern, or even single poles. All the legs are made to fold, and the whole can be packed in a bag and carried either in a cab or, for shorter distances, by hand. It is, of course, necessary to provide a tilting top, so that the camera can be adjusted while the operator is upon the ladder, and it is also well to have stops or discs to prevent the legs sinking into soft ground. The top should be of generous dimensions, so that the operator can stand in a position to focus and insert his slide safely and conveniently.

* * *

Tanks for Rapid Plates. An idea, common to many operators, is that extremely rapid plates must of necessity give thin negatives. This is quite erroneous, as it is possible to obtain extreme density if the development be thorough. Using what may be termed a normal developer, it will be found that nearly twice the time necessary for a slow plate must be given for the ultra rapid grades now coming into general use. Development may be expedited by increasing the quantity of alkali or by raising the temperature of the solution, but these courses are not to be recommended, as there is then a tendency to block up detail in the high lights. As the prolonged development necessary with a normal developer means a serious loss of time when a large number of exposures have to be dealt with, it is advisable to adopt the tank system, by which a couple of dozen plates can be developed in the time necessary for a quarter the number done in dishes. It is not necessary to use extremely dilute solutions for tank development, a strength which necessitates an immersion of twenty minutes being most convenient. Most tanks are rather wasteful of solution, the grooves being too wide, and there being space wasted at the ends and sides. The racks should fit the tank, and each groove should hold two plates back to back, thus allowing ample room for solution between the film sides. It must not be forgotten that pyro soda is as good in a tank as in a dish.

OVER-PRINTED BROMIDES.

THE best way to deal with over-printed bromides is to consign them at once to the waste box and correct the error by a fresh exposure. But it is not always convenient to do this, the fault only being discovered when the prints are dry, and then at a time when printing or enlarging is not practicable. Moreover, if the print is fairly large, the cost of the paper is a consideration, and it is worth while trying to save it.

The most obvious way of doing this is to employ one of the standard reducing solutions, as used for negatives, of course in a highly-diluted state, as the delicate image of the print would be quickly dissolved if a strong solution, as is used for negatives, were applied. Bleaching-out the image and re-developing has found some advocates, but in our experience the results so obtained have not been comparable with a print properly exposed in the first place, the effect being that of an over-exposed and under-developed print, if the development has been cut short, while practically a return to the original state comes with full development. A process of reduction, if carefully carried out, offers the best chance of success, and should not affect the colour of the deposit.

There are several formulæ which are suitable, but none which will bring very dark prints to a normal depth, as these are apt to become harsh under treatment. We therefore assume that only a moderate degree of reduction is necessary.

Before going farther it is worth remembering that a strongly-acid fixing bath, especially one fairly charged with amidol developer, has a considerable power of reduction, so that if dark prints are left in it for half an hour or more they may be lightened to the desired degree. This action is not equally strong upon all brands of paper, so that experiment is necessary before relying upon it.

Of the standard reducers there is none so satisfactory as a mixture of iodine and cyanide, which works evenly and does not affect the colour of the image. In deciding upon a working strength, we have here also to study the nature of our paper, or we may find that our image is damaged beyond reparation before we can stop the action. Two stock solutions should be prepared, one being a ten per cent. solution of iodine in iodide of potassium and the other a ten per cent. solution of potassium cyanide. The normal reducer for negatives is made by adding thirty minims of the iodine solution and five minims of the cyanide to each ounce of water. At this strength it may be used for cleaning up margins, or for quickly removing any unwanted portions of the image; for general reduction it should be diluted with two or three volumes of water. It should be noted that the energy of this

reducer depends upon the iodine which converts the metallic silver forming the image into a salt which is readily soluble in the cyanide, so that increasing the strength of the cyanide has little effect. The solution may be used in a dish, but in practice it is more convenient and economical to lay the print upon a glass plate or the upturned bottom of a porcelain dish, and to apply the reducer with a swab of cotton wool. By so doing, not only can a certain amount of local control be exercised, but, as only a small quantity of solution is present, there is little risk of running over the desired point. Five minutes' washing is ample after using this intensifier.

The well-known ferricyanide and hypo solution may be used in the same way, care being taken that only enough ferricyanide be used to give a very pale yellow colour to the mixture. The hypo may be rather stronger than is sometimes recommended, a ten per cent. solution being a good working strength. A plain, non-acid hypo bath must be used, and the ferricyanide should be freshly dissolved. These precautions will obviate the stains which sometimes occur. If used in a strong light the mixed solutions rapidly become decolourised and inert.

A convenient method for use with large prints is that of successive immersion in a weak solution of iodine and hypo solution. To enough water to cover the print well is added the aqueous solution of iodine, previously mentioned, until a deep straw tint is obtained. The print is laid in this, and the dish rocked until the blue colour, which immediately appears on the back, is visible in the high-lights of the picture. After rinsing, a twenty per cent. hypo bath is applied, and allowed to remain for at least ten minutes. If the reduction be insufficient, the whole process may be repeated, after thoroughly washing, any trace of hypo being sufficient to stop the action of the iodine.

Prints which have been toned by bleaching and sulphiding, or which have been thoroughly toned with hypo-alum or liver of sulphur, can be reduced with the iodine-cyanide solution, but as a rule the tone will be rendered rather warmer. A much stronger solution may be used than is permissible with black-and-white prints.

The semi-mechanical reducers which act by dissolving a portion of the gelatine film, such as eau-de-javelle or Milton, do not work well upon bromide prints, no matter how weak they may be. They have a tendency to remove the deposit entirely from the high-lights, and to give a harsh, patchy effect.

When contrasty effects are desired from thin negatives, it is sometimes advisable to over-expose deliberately, to over-develop, and then to "clean up" by one of the methods given. This is especially valuable with line subjects which have a tendency to print through. Quite a deep grey tint may be removed and the lines still left of greater depth than would be possible with simple exposure and development.

We have lately handled some samples of paper which did not allow of the film being rubbed with cotton wool while wet. If such are encountered, the reduction must, of course, be carried out by immersing the print and keeping the dish well rocked.

BLOCKING OUT NEGATIVES.

Blocking out is not so difficult an art as retouching, yet really good hands at blocking out are not often met with, even expert retouchers sometimes being unable to block out a negative in a convincing manner.

A negative that has been correctly blocked out will print as though it had been taken against a white ground, and will deceive the uninitiated always and sometimes the expert also, and this kind of blocking out is the only kind that matters.

The essential tools for this work are a couple of good sables, some water colour, a knife, and some cottonwool or washleather. A common mistake is to choose a very fine brush. A stout short-haired sable is essential, and its size should depend on the detail of the negative. For a half-plate head a No. 3 or 4 sable will not be too large if the point is good. For machine studies, smaller brushes may be needed for very fine detail, but should not be used otherwise. For filling up, a large camel-hair mop will save time, while a stencil brush is useful for softening outlines of hair, etc. Indian red paint and Payne's grey or neutral tint are very useful, though Photopake can be used instead of the red if desired. For commercial negatives a short steel straight-edge, a draughtsman's "curve," and a ruling pen are also wanted.

The first thing to do is to see that brushes are clean and in condition, that the paint is mixed well and of a good consistency, and that the negative is clean. It is always a sound plan to go carefully over the surface to be painted on with a damp leather or swab of wool, as the slightest trace of grease or other foreign matter may spoil the job completely. With glass negatives it is usually best and easiest to work on the glass side (this does not apply to commercial photographs), as this side will always clean quickly and take paint well, besides giving diffusion in printing. Exceptions are large negatives of "indented" subjects, such as full-length groups. Blocking out on the glass side of such pictures may prove difficult, if not impossible, to do in such a way that it will everywhere print in correct register with the image. With single figures it very seldom happens that this difficulty crops up provided the work is done with the eye directly over the centre of the figure all the time, and the negative is kept flat on the desk. This latter, by the way, is as well lowered rather more than is usual for retouching, though that may be a matter of taste. When the rule and pen are used, however, the more the desk approaches to the horizontal the better.

Having decided which side of the negative to work on, the brush is loaded and brought to a point. For all definite outlines red paint is the best. For hair and other soft lines blue or grey is better. With the negative on the desk a line can be started off at any point on the side against the brush hand. In the illustration the first operation is marked out in black with arrows showing the direction of the different strokes used. With this negative glass side up, and right way up on the desk, a convenient point for a right-handed worker to start would be where the hair joins the neck. From there a bold sweeping line is drawn downwards, following the outline of the neck, beads and blouse. Had the latter two been prominent breaks in the flow of the line, one sweep would not have served. The procedure then would have been more like that for the bottom line of the back hair, which was done with a number of distinct strokes; in this case, back-hand ones. Turning the negative half round to the right, so that the top comes against the brush, the stroke A is put in back-hand, and the various top curves with separate up-and-down strokes, following the direction that is most convenient in each case. Wherever there is a definite corner, it is always

best to start outwards from it. Don't run into it, and, above all, don't run over it and continue without a break. Outlines like these are best done in definite sections, each section meeting its neighbours in a clean join. Turning the negative upside down, the tip of the nose offers a good starting place. From there, working downwards, three decided sweeps will join up with the part just done. But they must be decided sweeps, particularly the line on the nose. Any hesitating, creeping, niggledy line here would ruin the resemblance, the blocking out, and the photograph. With the negative turned yet a little more, the mouth is covered with three short curves, done backward in this case, though downward strokes might be easier at first. The line between the chin and shoulder is composed of two lines, one done with the face of the picture looking down, and the other with the negative turned the other way up. The heavy sweep on the arm is started from

Print from partially blocked-out negative illustrating method of working.

the margin and run to the bend of the shoulder, where a backhand stroke, which could also have been done in the other direction, joins it to the line from under the chin.

Having completed the outline, it is examined for inaccuracies, any small deflections from the truth, unless done deliberately with the object of improving the shape of the head or features, may possibly be remedied without washing out and re-doing. A raggy outline of hair may be improved with a smudge of blue or grey paint well stippled with the stencil brush, though it is difficult to do this so as to get a good effect on the print. If the paint has gone too close anywhere, it can be eased away with a clean damp brush if on the film side, or a sharp knife if on the glass. With the outline correct, it is a simple matter to fill up with a large brush or mop, but the paint should be fairly thick, and a coat on each side will do no harm. If drying is required to be quick, spirit should be added to the paint instead of water when mixing for use.

Commercial negatives, of furniture, machinery, etc., are best done on the film side, as it is easier to rule clean straight lines on this side. A little practice may be necessary to get into the way of handling a ruling pen, but it is not at all difficult. A good load of paint should be taken up between the points, and its consistency is important. If it is thick, the extreme point will soon clog. If it is thin there will be a danger of blotting from the edge of the rule. A common trick with draughtsmen is to draw the pen over the back of the hand, the skin being able to start the flow more readily than even paper will, and much more readily than gelatine often does. Once started, the paint will flow until the pen is empty, provided it is not put down for long enough to let the point dry. In drawing a line with the pen, one should aim at starting and finishing one-sixteenth of an inch short. In this way the complete line is cleanly covered, as a rule. If there is anything short, it can be easily filled in after; but an over-run is hard and messy to clean out. When it is necessary to clean off a line, it should be done with a clean, sharp "swipe," with a wet leather or swab, starting from inside and clearing the paint over the unwanted part of the negative. Curves are often done freehand, but wheels are rather hard to do cleanly without guides, and the "draughtsman's curve" will assist very often in getting a more definite line. These "curves" can be bought in an endless variety of shapes, and a good one will provide guidance for a large number of bends and corners. A little practice is necessary before one can use a curve with confidence; it is rather hard to keep the pen point parallel to the curve all the way round, the resulting line often being clean enough but not exactly in register.

To finish off a blocked-out negative, it is necessary to make some allowance for the base of the picture. A blocked-out figure cannot be left to stand on nothing, neither can a blocked-out railway engine. The former can be put right by scraping away some of the paint round the shadow side of the feet, preferably in zig-zag lines. The engine would look all right if a length of line were left under each side of wheels, and a stationary machine or piece of furniture should have a little flooring left in the form of a square, not forgetting the perspective when designing the square. Of course, if an air-brush is in use, grounds can be put in on each separate print, but when the photograph can be taken on a clean and light floor, the original ground has advantages, and should be partially included, leaving just enough to give stability to the picture. For block-making purposes, a photograph can be completely blocked out and the ground left to the fancy of the block-maker's artist if desired.

Forethought helps a lot with machine and furniture photographs, and if a sheet is stretched behind the object before photographing, the subsequent work will be easier. A print made previous to blocking out will also help. It is almost essential in the case of a machine photographed with other machinery behind it. Very fine detail, such as electric wires, is very difficult to block out, and very often it is best to paint it over entirely and restore it with a sharp knife when the paint is quite dry. The most difficult thing I have ever struck of this kind, is the wiring of an O.E.T. crane, it being impossible to block it out or to recut it decently. In this case, I think the most satisfactory way is to paint over all the wires, leaving the insulators distinct, and to draw in the wires with a retouching pencil on the prints. If technical accuracy is necessary, a blue print of the wiring can be requisitioned to make things clear and prevent a wrong number of wires being added. Another dodge which has proved useful is to do any long straight lines with strips of lantern-slide binding, instead of using the pen. In the case of a piano

this may prove quicker and easier, if the round corners are carefully tackled with the brush.

Blocking out can be protected against scraping by covering with thin gummed paper, or varnishing. Without either of these coverings a negative must be kept in a tissue envelope or it may soon meet with damage or else damage other negatives with which it comes in contact.

THERMIT.

PHOTOGRAPHIC METHODS OF TESTING DEVELOPERS

[A communication from the Research Laboratory of the Eastman Kodak Company, reprinted from the "American Annual of Photography." The Elon mentioned, it may be stated, is metol (monomethyl paramidophenol sulphate) of Eastman manufacture.]

One of the many problems assigned to the Photographic Department of the Research Laboratory of the Eastman Kodak Company is the working out of better developing formulæ, which involves the testing of developers submitted from outside sources. Years of experience in this connection has shown that only a surprisingly small number of different developing formulæ are necessary to develop every type of emulsion successfully, and that in spite of the numerous developing agents of varying chemical composition at present available, pyro, Elon, and hydroquinone still remain unequalled, though para-amidophenol, glycin, methyl-o-amidophenol, and diamidophenol are useful for special purposes.

Instead of adhering strictly to the manufacturers' published formulæ, almost every photographer has his own pet formula with a reputation in many cases entirely undeserved, because the formula was not compared with the manufacturer's formula under equally favourable conditions. These remarks apply also with regard to developing agents. Some photographers use developing agents of unknown composition with supposedly mysterious properties, although careful comparative tests would undoubtedly prove that the developing agents in question are no better than the standard known developers.

In this article it is the object of the author to explain how by simple tests the photographer may judge the merits of any developing agent or developing formula with accuracy.

Two methods of testing are possible:

1. The absolute method, by means of which the various properties of a developer are expressed numerically, and

2. The comparative method, whereby the developer to be tested is compared side by side and under identical conditions with a standard developer.

The first method is obviously the ideal one, because if we can measure the properties of a substance and express them in numbers, then we really know something about that substance. Without the necessary apparatus, however, it is not possible for the photographer to express his various tests numerically, but by comparing a developer side by side with a standard, he is usually in a position to judge the merits of the developer with sufficient accuracy for all practical purposes.[1]

Classification of Developers.

In photographic practice, the word "developer" is used synonymously with a developing agent, a complete developing solution ready for use, and a developing formula, so that developers may be classified as follows:

1. Developing agents.
   - *a.* Composition known.
   - *b.* Composition unknown.
2. Developers ready for use.
   - *a.* Composition known.
   - *b.* Composition unknown.
3. Developing formulæ.

1-*a*. In order to test a developing agent of known composition, say hydroquinone, it should be compared with a known pure sample of the same developing agent by compounding a standard developing formula with both chemicals and then comparing the two developers so obtained.

A suitable standard developer formula is the following:—

	Metric.	*Avoirdupois*
Developing agent	5 gms.	75 grs.
Sodium sulphite (E.K. Co.)	50 gms.	1¾ ozs.
Sodium carbonate (E.K. Co.)	25 gms.	375 grs.
Potassium bromide	1.5 gms.	20 grs.
Water to	1 litre	32 ozs.

1-*b*. A developing agent of unknown composition is compounded according to the above formula and compared with a known developing formula used for average work. Such a developer, known as MQ-25,[2] is prepared according to the above formula, using 1.25 gms. of Elon and 3.75 gms. of hydroquinone as the developing agent.

2. A ready-made developer is compared with MQ-25 or with a known satisfactory developer.

3. The behaviour of a developer prepared according to a new formula is compared with that of the best previously known formula for the particular purpose in question.

The Emulsion to be Tested.

Since the behaviour of a photographic material towards developers is usually independent of the support on which the sensitive emulsion is coated, we will refer only to the action of developers on emulsions.

We cannot comprehensively speak of the properties of a developer without referring to the emulsion which is developed, and, *vice versâ*, when speaking of the properties of an emulsion, we refer to them in connection with a particular developer.

Most developing formulæ are particularly adapted for particular classes of emulsions, and should be compared on representative emulsions in such classes as follows:—

Negative emulsions	NC film. Commercial film. Process film.
Positive emulsions	Positive motion picture film. Seed Lantern plates.
Paper emulsions	Velox. Bromide and Artura Iris.

Mixing the Developer.

When compounding test developers from the solid developing agent, it is important to weigh out the various ingredients very carefully in order to insure an accurate comparison. Instead of weighing out small quantities of potassium bromide it is more accurate to measure out the required volume of a 10 per cent. solution.

Since a developer which gives bad chemical fog is useless, and since more developers are rejected on account of fog than for any other defect, it is important that the rules of mixing developers be carefully observed so that no fogging agents are produced during mixing. As a general rule, the sulphite should be dissolved first, each chemical thoroughly dissolved before the next one is added, and the developer mixed at as low a temperature as possible, otherwise the developer will give fog even if prepared from the purest chemicals. A report on a developer incorrectly mixed is absolutely worthless, because there is no way of telling whether the fog was inherent in the developer or was a result of incorrect mixing.

To mix the above test formula given above proceed as follows:—

Dissolve the sulphite in about 300 ccs. or 10 ozs. of luke-warm water; then add the developer hydroquinone or both, and allow to cool. Meanwhile dissolve the carbonate in 300 ccs. of luke-warm water, add the bromide and cool. Now add the carbonate solution to the sulphite solution and add cold water to make 32 ozs. or 1 litre.[3]

1. Chemical methods of testing developing agents have been fully described by H. T. Clarke ("Jour. Ind. Eng. Chem.," Nov., 1918

2 The suffix ... per cent. of the total developing agent consists of ... Simplified Method of Writing Developing Formulæ ... K. Metol ... "B.J.," 1917, p. 535.

3. See "How to Prevent Photographic Solutions," by J. I. Crabtree ("B.J." ... Chemical Fog" ("Amer. Ann.," 1919, p. 20).

Sensitometric Methods.

When we expose a plate or film in a camera focussed on a landscape, we impress upon the emulsion areas of light of varying sizes and of varying brightness. After development the negative consists of areas of varying sizes and varying opacity or density, the relation of the density of a given area to the intensity of the light producing it for the particular emulsion depending upon the developer and the time of development.

The density of any particular portion of a negative is a measure of its capacity for stopping light and is proportional to the total mass of silver comprising that portion. It can be measured by chemical analysis, but much more readily by an optical instrument by comparison with a standard density. In the case of an average amateur negative the density of the shadows will average 0.25 to .04 and the density of the high-lights from 1.2 to 1.8. One way of comparing the behaviour of two developers is to expose two films in a camera on the same subject, giving the same exposure, develop them side by side and compare the densities of corresponding areas of the shadows, middle tones and high lights of the resultant negatives. This method is not entirely satisfactory because very few areas of uniform density are large enough to permit of measurement, and it is not possible to place any two areas which received the same exposures side by side so as to compare the densities visually.

It is much more simple, therefore, to expose a negative in steps of gradually increasing exposures so as to correspond with the shadows, middle tones and high-lights of a subject and use these graded test strips in place of actual camera-exposed films because the developed strips may be placed side by side and a comparison made of the densities of steps which received identical exposures.

How to Expose a Step Negative.

When measuring the characteristics of a developer in absolute units, it is necessary to use a standard light-source and a special rotating disc or drop shutter for obtaining the graded exposures, but for comparison purposes it is simply necessary to give the test emulsion about six different steps in exposure, the lowest step being given such an exposure that after development the step will be just visible. The exact ratio of the exposures of the various steps is not important but should be of the order 1, 2, 4, 8, and 16.

To prepare a number of test strips, proceed as follows:

Take a 7×5 or 10×8 sheet of the film coated with the particular emulsion to be tested, place in a printing frame, and cover with an opaque card. Now, make a preliminary test to ascertain the distance from the exposing light so that an exposure, say of two seconds, is required to produce a just visible deposit on the film when developed in the standard developer for an average time. Then place the frame containing the sheet of film to be exposed at this determined distance from the light source, and shift the card so as to expose a strip of the film in the frame for 16 seconds. Then expose new steps after the expiration of 8, 4, 2,

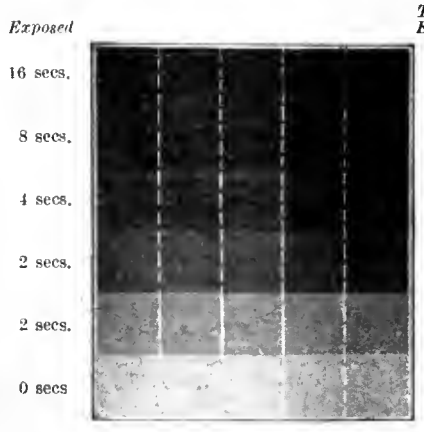

Fig. 1.—Method of exposing test film and cutting into graded test strips.

and 1 seconds respectively. The last step should be unexposed so as to serve as a fog test strip. The various steps have, therefore, received exposures of 0, 2, 4, 8, 12, and 32 seconds respectively (fig. 1). Now, cut the film lengthwise along the dotted lines so as to give a number of graded test strips.

A quicker method than the above, if a large number of test strips have to be prepared, is to expose a 10×8 or 7×5 sheet of film as above, and develop this without cutting along the dotted lines. This graded strip negative can then be used as a master negative for printing test strips, the printing exposure being so adjusted, as described above, that the least exposed step is just visible after development.

For purposes of comparing developers, the exact ratio of the exposures for the various steps is unimportant, though it is not advisable to make the ratio of successive exposure steps greater than the power of 2.

In some cases it is sufficient to make comparative tests on strips of film which received only one step in exposure, which are known as "flashed strips." To prepare a number of flashed strips expose one half of a large sheet of film so that after development the density will be a little less than unity. This would correspond to a middle tone of an average negative, and objects should be just visible on looking through the flashed half of the developed film. The unexposed half serves for the fog test. The large sheet should then be cut lengthwise so as to give a number of test strips which all received the same exposure.

The Use of Graded and Flashed Test Strips.

Flashed strips give only a comparative measure of the maximum density produced by the developers. When comparing two similar developing agents for purity or when comparing contrast developers, flashed strip tests usually supply all of the information required. If developers are to be compared for detail rendering power and for contrast, then graded strips should always be used.

How to Interpret Test Strips After Development.

After development the graded test strips will appear as in fig. 2. The lowest step, *a*, is a measure of the fog produced by development, since this step did not receive any exposure.

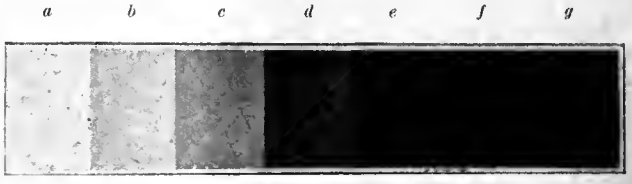

Fig. 2.—A step negative as it appears after development.

Always think of the first step, *b*, and the last step say, *g*, as corresponding to the shadows and high-lights in the subject photographed, the intermediate steps corresponding to the various tones of the subject. The density of *b* is a measure of the detail-giving power of the developer, while the difference between *g* and *b* gives the density contrast. In the case of developers required to render a minimum exposure, say for high speed photography, the difference in density between *a* and *b* should be as great as possible with enough difference between *b* and *g* to give a sufficiently contrasty print, but with a developer intended for, say, line work, the density of *a* should be as low as possible; that is, the developer should be free from fog, while that of *b* and *g* should be as great as possible.

Factors to be Considered when Comparing Developers.

An ideal developer is one which will develop rapidly, give good contrast and shadow detail without producing chemical fog, and which will deteriorate only slowly; that is, if it has good keeping qualities. Other factors are of less importance. The specifications of ideal developers for various purposes, of course, differ. For instance, if the most is to be secured from an under-exposed negative, it should be developed in a tray with a developer containing caustic alkali, this developer keeping active for only a very short time. In the case of amateur finishers' and motion picture film laboratories, a developer is required which will develop a normally exposed negative in from 5 to 15 minutes, but the developer must also keep in active condition for two or three weeks.

In order, therefore, to enable the reader to interpret the results of his tests, it is necessary first to study the various characteristics of a developer.

The Developing Power.

When we speak of "developing power," we are using a somewhat vague term in an attempt to sum up several characteristics of the developer in one word. An accurate description of a developer cannot be given briefly, because one developer may be very powerful as regards giving extreme contrast regardless of time, while another may be very energetic and give a normal negative quickly, but is incapable of giving extreme contrast. We may consider "developing power," therefore, as being made up of the following factors:—

(a). Time of Appearance of the Image.

Every photographer has observed that after placing the negative in the developer, the time required for the first signs of the image to appear varies with different developers. The time of appearance is not an exact measure of the speed of development, because this depends also on the rate of diffusion of the developer and reaction products in and out of the gelatine film, though as a rule with a rapid working developer the time of appearance is short.

With a developer of the Elon type, the time of appearance is very short, but the image subsequently builds up slowly. With hydroquinone the time of appearance is much longer, but the image then builds up rapidly. The difference in behaviour of these two developers is illustrated in fig. 3.

Graded strips which had received the same exposure were developed in an all Elon developer (MQ-100) and in an all hydroquinone (MQ-0) developer side by side and a strip removed from each developer at regular time intervals. After one minute all the steps were visible on the Elon strip, but only the heavier exposures or high-lights were visible on the hydroquinone strip. At the end of two minutes the lower tones corresponding to the shadows in a photograph were just visible on the hydroquinone strip, but at the end of four minutes both strips looked almost alike.

When using developers of the Elon type, if the image is examined by inspection, the photographer is apt to remove the film from the developer too soon, because he is misled by the rapid appearance of the image, though from the above it is seen that to secure the same density contrast it is necessary to develop for almost the same time. We say, therefore, that Elon has a high development factor and hydroquinone a low one the development factor, or Watkins factor, being equal to the total time of development divided by the time of appearance of the image.

When comparing two developer samples, say hydroquinone, by testing developers prepared from them according to the same

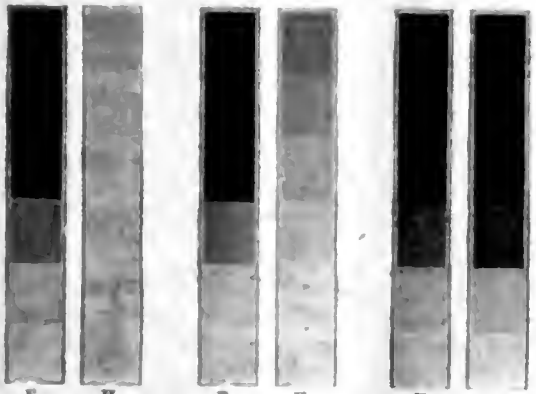

Fig 3.—Developed graded strips showing the difference in behaviour between Elon and hydroquinone.

formula, the time of appearance of the image is inversely proportional to the percentage of pure developing agent in the samples. With other developers it is a rough measure of the detail-rendering power; that is, if the image flashes up quickly and the negative is not over-exposed, then we are reasonably sure that all the shadow tones will be developed out.

(b). The Rate of Development after the Image Appears

Development consists in reducing the exposed grains of silver bromide contained in the emulsion to metallic silver. All the grains do not commence to develop at the same time, because they are distributed throughout a more or less thick layer of gelatine, but the rate at which the grains develop as a whole depends on the number of unexposed grains remaining to be developed. Therefore, as development proceeds and the number of undeveloped grains remaining becomes smaller, a fewer number of grains

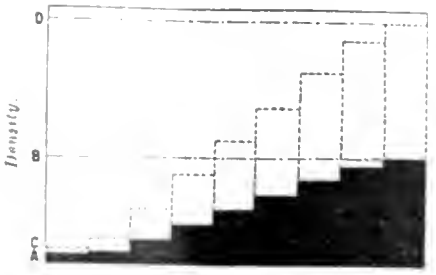

Fig. 4.—Showing the growth of density of the image during development

develops in each minute until finally it is not worth while to prolong development, because the unexposed grains then commence to be reduced to silver at a greater rate than the remaining exposed grains.

The growth of the image as a result of the development of the silver bromide grains is referred to as the growth of density, and in the case of a graded strip negative the density of the middle steps increases in the same proportion, but the lower and higher steps do not grow quite so fast. Fig. 4 represents a cross section of a strip negative developed for, say, one minute. The difference between the lowest and highest steps (*ab*) or density contrast is very small. On prolonged development each step has increased in density, and the density contrast (*cd*) is much greater than (*ab*).

The density contrast of a negative is governed both by the difference in brightness between the high-lights and shadows of the subject and by the degree of development of the negative. In order therefore to maintain the density contrast of a batch of negatives as constant as possible, films exposed on a flatly lighted subject should be fully developed, but those exposed on a contrasty subject should be developed to a less extent.

Density contrast should be carefully differentiated from *general density*. An over-exposed and under-developed negative will have good density in the shadows, but the high-lights will not be much more dense; that is, the negative as a whole will look dense but the density contrast will be small. The *maximum density contrast* is the greatest density contrast obtainable by prolonged development until fog begins to form at a greater rate than the image.

As regards maximum density contrast and speed of development, developers fall into four classes as follows:—

(a) High maximum contrast and high speed of development; that is, the negative rapidly obtains great general density and contrast. In terms of the step negative (fig. 2), the density of *b* is fairly high and the density difference *g b* is great also. Developers of this type are Elon-hydroquinone or pyro developers in combination with a caustic alkali.

(b) Low maximum contrast and high speed of development. Elon developers are of this type; that is, the image flashes up but fails to build up great density. In terms of the step negative, the density of *b* is fairly high, but the difference *g b* is comparatively small.

(c) High maximum contrast and low speed of development. Hydroquinone is a typical developer in this class; that is, the image appears slowly, but good density and contrast are finally obtained.

(d) Low maximum contrast and low speed of development; that is, the image appears slowly and development proceeds slowly, so that good contrast is not obtained.

(c) The Power of a Developer to Render Visible a Minimum Exposure.

For most photographic work this property of the developer is perhaps the most important. Contrast in a negative is not so important owing to the use of the large variety of printing media of varying contrast which take care of negatives of varying contrast. Referring to the step negative (Fig. 2), the detail giving power of the developer is measured by the difference between the density

steps *a* and *b*. This is obviously the greater the less the fogging power of the developer. The detail-giving power is usually lowered by the addition of potassium bromide, which addition is analogous to cutting off the same amount of density from each step.

The relative effect of bromide on density is greater on the first step than on the last, and this is why when testing a developer it is advisable to omit the bromide from the test formula. With some very energetic developers, however, it is advantageous to add a certain amount of bromide, because in some cases bromide restrains fog more than the image. In other words, suppose that in five minutes without bromide step *b* had a density of 0.4 and then fog commenced to form. In the next five minutes, suppose a fog density of 0.2 was formed and the total density of *b* only grew to 0.5. The effective density contrast is, therefore, 0.3. Now suppose the addition of potassium bromide cut down the density of step *b* to 0.45 and cut the fog down to 0.05. Then the density contrast or effective density of *b* is 0.4, showing the advantage of adding bromide.

J. I. CRABTREE.

(To be continued.)

THE CONTRAST RATING OF GASLIGHT AND BROMIDE PAPERS.

(A paper read at a recent meeting under the control of the Scientific and Technical Group of the Royal Photographic Society.)

THERE is a legitimate desire on the part of photographers to be provided by the manufacturers of photographic materials with as much reliable information concerning them as possible. A demand has arisen of late for the publication of some measure of the contrast-giving quality of various printing papers in place of the vague descriptions, such as "hard" and "soft," etc., which prevail at present.

The subject can be profitably discussed under the following headings, namely:—

(*a*) Whether the contrast quality of a paper can be described by one or more numerical constants of the emulsion, and if so,

(*b*) Whether there are difficulties which prevent the publication of these constants being of real value in practical photography, and

(*c*) Whether there is any alternative scheme.

In considering this matter, we are dealing with the objective phase of tone reproduction alone, and we are not concerned with the conditions which must be fulfilled to ensure exact tone reproduction involving the subjective phase as well. A complete picture of the capacity of any one printing paper to render tones is given by the characteristic curve. If two printing papers yield identical characteristic curves, they will produce similar prints from the same negative, and their respective contrast qualities will be identical. It is equally true that any lack of coincidence of the course of the characteristic curves of two papers will indicate that prints from the same negative on these papers will differ to some degree. The first part of the problem resolves itself, therefore, into a description of the paper curve if possible in a simple manner, so that the description shall be useful in practical photography. A typical paper characteristic curve (ABCD) is depicted in Fig. 1.

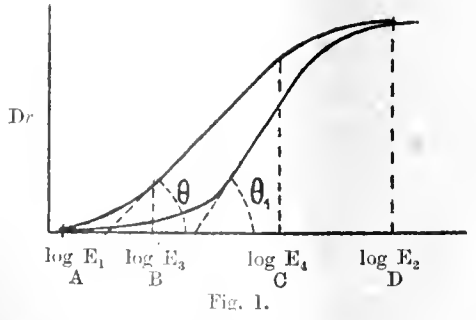

Fig. 1.

This curve is obtained by plotting the reflexion densities of the paper obtained by full development against the logarithm of the exposures that give rise to them. The reflexion densities of a paper are measurements fulfilling the equation

$Dr = \log \frac{1}{R}$, where R is the reflecting power measured decimally when the silver deposit on the paper is illuminated by a narrow pencil of light at an angle of 45° and viewed at an angle of 90°. The measurement is analogous to the H. and D. density measurement in the case of plates where $D = \log \frac{1}{T}$, T being the transparency of the silver deposit under measurement. A paper density reflecting 5 per cent. of the light reflected by the white paper base is a density of 1.3, since

$$Dr = \log \frac{1}{R} = \frac{1}{.05} = \log 20 = 1.3.$$

The characteristic curve of the paper derived in this manner exhibits the following features:—

Total Scale (Exposure Range or Exposure Scale).—In Fig. 1 an exposure E_1 gives rise to the faintest discernible tone upon the paper and E_2 gives rise to the deepest black. The ratio $\frac{E_1}{E_2}$ gives the total scale of the paper. It is that range of exposure which enables the paper to record all possible tones from the faintest grey to the deepest black

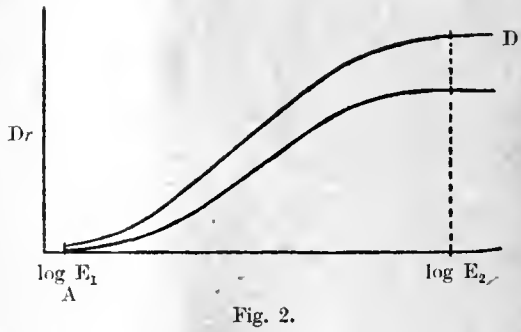

Fig. 2.

upon full development. *In practical printing this measurement is subject to a modification mentioned later.* Roughly speaking the total scale of vigorous gaslight paper is 1 to 10 and that of a soft bromide paper 1 to 50. Soft gaslight papers and hard bromide papers occupy intermediate positions. The usual condition of successful printing is that the total scale of the paper in logarithmic units should be equal to or slightly greater than the density scale of the negative. Whereas two papers with the same total scale may yield similar prints from the same negative, two papers with different total scales can never yield prints of the same appearance from the same negative. The total scale is, therefore, an important measurement descriptive of one feature of the characteristic curve of the paper. Recently this measurement alone has been suggested as a measure of the contrast quality of a paper. Alone it would be inadequate.

Gamma.—As in the case of plates, so in the case of papers, the straight line portion of the characteristic curve (BC in Fig. 1) when produced downwards will intersect the exposure axis at an angle (θ in Fig. 1). The tangent of this angle is the gamma of the paper. It is the recognised practice of skilled photographers to develop gaslight and bromide papers fully. It is known that whereas the gamma of a paper increases as development progresses in just the same manner as it does in the case of plates, yet after a comparatively short time of development, considerably short in fact of the development time used by good workers, the gamma obtained is the maximum gamma of the

paper and further development occasions no further increase. The gamma of a paper is therefore the gamma infinity (γ_∞) of that paper. A vigorous gaslight paper yields a gamma infinity of 2.0 or somewhat over, and a soft bromide paper may yield a gamma of about 1.3 approximately.

In Fig. 1 are depicted the characteristic curves of two papers with the same total scale but different values for gamma (θ and θ_1). They would yield different prints from the same negative. The characteristic curves of two papers cannot coincide unless both the exposure scale and gamma measurements are equal respectively. It is therefore necessary to know both these measurements if the contrast quality of the paper is to be defined.

Maximum Density.—The maximum density of the paper (D in Fig. 2) is a measurement of great practical importance. Other things being equal, the deeper the black that a paper will yield, the more it is esteemed for practical print production. The surface of the paper has a marked influence upon this measurement. With similar emulsions the depth of black is determined by the "glossiness" of the paper surface: the more glossy it is the deeper the black recorded. With similar paper surfaces the depth of the black is determined by the nature of the emulsion: the deeper the black the better the emulsion. In Fig. 2 are depicted two paper curves with similar total scale measurements, but different measurements for the maximum density (D and D_1). These papers would yield prints of a different character from the same negative. It is necessary, therefore, to add the measure of the maximum density (black) to the constants total scale and gamma already described.

Rendering Power.—By this term is meant the capacity of a paper to reproduce the negative gradations with relative fidelity. Relatively true reproduction is confined to the tones which lie upon the straight line portion of the paper curve. Other things being equal, the paper with the longer straight line portion of the characteristic curve in comparison with the total length of the curve is the better paper. In Fig. 1 the whole curve *AD* subtends an exposure scale from E_1 to E_2. Of this whole curve the portion *BC* is straight, and subtends an exposure scale from E_3 to E_4. The rendering power is $\frac{\log E_4 - \log E_3}{\log E_2 - \log E_1}$ and, being a fraction, it is usual to multiply it by 10 for convenience. Very few papers have more than half their total curve straight equivalent to a rendering power of 5. A poor paper may have a rendering power of less than 2, indicating that it is capable

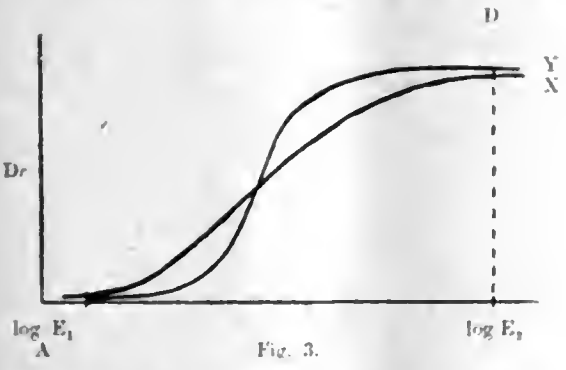

Fig. 3.

of rendering but few tones with truth at one and the same time. Papers of good and bad rendering powers (X and Y) are depicted in Fig. 3.

They possess the same total scale and the same maximum density, but the lack of coincidence of the curves indicates to what extent prints upon them from the same negative would differ.

The four constants described would by their equality indicate with a fair degree of precision that the paper curves were identical and that similar prints could be expected from the same negative.

Summarised, they are measurements of—(1) Gamma infinity. (2) Total scale. (3) Maximum density. (4) Rendering power.

No one of these constants is sufficiently descriptive of the contrast quality of the paper to be a reliable indication of the character of the print that it would yield, but it would be as well to consider whether their number can be reduced without making the information conveyed by the reduced number practically useless

In the first place, however, I will consider some of the difficulties, if any, which may prevent all or any of these measurements being of real practical value in photography.

Age of the Printing Paper.—It is an unfortunate fact that with age and the influence of storage conditions the emulsion constants change. Granting their truth when computed by the paper manufacturer, the paper when it reaches the user may have changed sufficiently to negative the value of the measurements. When perfectly fresh paper can be obtained this objection vanishes.

The Measurement of the Total Scale and of the Maximum Black.—It might at first sight be considered that the total scale should be the range of exposures embraced by the whole characteristic curve from the foot to the summit (PM in Fig. 4.) In ordinary printing this is not practicable, and the total scale which can be utilised at any one time

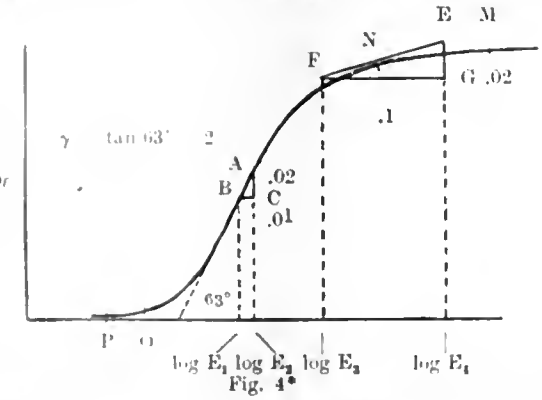

Fig. 4*

is considerably short of this. The extent to which modification of the total scale and maximum black is needed in practice is illustrated in Fig. 4.

Let the gamma of this paper be 2, so that the angle made by the straight line portion with the log exposure axis is 63°. Choose two points A and B on the straight line portion of the paper curves so that density A is just perceptibly darker than density B. The difference between A and B will be about 0.02. Construct the right-angled triangle ABC so that AC = 0.02. Then from tangent ABC = $\frac{AC}{BC}$ we have 2 = $\frac{.02}{BC}$ ∴ BC = .01. But BC = $\log E_2 - \log E_1$, therefore the exposure increase required to give the least perceptible difference in paper densities lying upon the straight line portion of the curve is 0.01 in log units, or an increase in exposure of 2½ per cent. in ordinary units.

Now consider the "shoulder" of the paper curve. Choose a point N and draw FE as a tangent. Complete the right-angled triangle FEG so that EG = 0.02 and represents the smallest perceptible paper density difference. Just as BC represented an exposure required to register a paper density difference lower down in the curve, so does FG represent another exposure difference necessary to record the least perceptible paper density difference at N. Obviously FG is greater than BC, and the higher the point N is placed the greater FG becomes. If the angle EFG be 11° then as tangent 11° is $\frac{1}{5}$, FG must equal 0.1. An exposure difference ($\log E_4 - \log E_3$) of 0.1 is equivalent to a 25 per cent. increase in exposure in order to record a least perceptible paper tone difference. A fundamental difference between the paper densities lying on the straight line portion and those on the curved portions of the paper characteristic curve is that the latter require very much greater exposure differences, and hence greater negative density differences, to bring out the paper tones, and the matter becomes worse the higher the point N be taken or the lower the point O. No negatives made will comply with these paper requirements driven to extremes. It has been considered by Mees, Nutting and Jones that when it takes more than 25 per cent. increase in exposure to register a separate paper tone, the useful limit of the paper in practical printing has been reached. Practically speaking, then, the total scale is represented by the exposure range required to give O N and not P M and the maximum black in practice is N and not M. The points N and O are such that the gradient of the curve at those points $\left(\frac{d D}{d \log E}\right) = 0.2$. It remains for this

* This figure is purely diagrammatic, and is exaggerated for the sake of clearness.

meeting to decide whether manufacturers can agree to such a standard for total scale and maximum black. It is to be feared that both these measurements may become the butt of competitive advertising, and that the larger they are the better they will be considered by the public. It is almost certain that the scale PM will be chosen by some manufacturers, and also M as a measure of black. If that be so, the utility of the measurements in practical work will be largely nullified.

The Measurement of Gamma.—This should present little difficulty. The gamma required is that attained on full development (γ_∞). The prevalence of under-development on the part of paper-users will tend to prevent them from deriving the full benefit from the information that a γ_∞ measurement gives. However, that will be the fault of the users.

The Measurement of Rendering Power.—The need for a conventional measurement of total scale has been mentioned. As the rendering power is a relationship between that portion of the characteristic curve which is straight and the total scale, and as the length of the straight line portion is occasionally a matter of opinion, I can see but little hope that manufacturers' figures will be comparable. It is also extremely unlikely that papermakers are going to advertise a low rendering power when they happen to be so unfortunate as to make a batch of paper less good than usual. I am convinced that this difficulty will exist and that it is a very real one. It is equally applicable to all sensitometric measurements indicative of quality.

It would appear, therefore, that there are a considerable number of difficulties to overcome in order that the four constants described can be published and serve as a measure of the contrast-giving qualities of a printing paper. These difficulties diminish if we can decide to discard some of the constants and regard one, or possibly two, of them as sufficiently descriptive to serve our present purpose. I regard the measurement of the gamma infinity as absolutely essential. I would like to retain the measurement of the total scale if possible, and thus make the gamma and total scale the minimum requirement of a statement as to contrast quality. I think that the maximum density and the rendering power could be discarded, although to those who appreciate their significance these constants convey eloquent information as to the quality of the paper. It seems to me that this meeting might consider to what extent the gamma infinity alone would constitute a satisfactory measure of the paper contrast. In my experience it is seldom that a developing out paper when fully developed yields a characteristic curve with an angle of less than 50° to the exposure axis, nor is it usual for the slope of a vigorous paper to be more than 70°. The tangent of the former (gamma) is 1.2 and that of the latter about 2.6. I can see no objection to the use of the actual gamma figures on the paper package, though some manufacturers may prefer to use letters or marks synonymous therewith.

So far as we have gone, therefore, I am of the opinion that—(1) The contrast quality of a paper can be fully described by the measurement of:—(*a*) Gamma infinity. (*b*) Total scale. (*c*) Maximum density. (*d*) Rendering power.

(2) Of these four constants the gamma infinity measurement is essential, the total scale very desirable, and the remaining two are probably optional so far as an approximate contrast description is concerned.

(3) A stale or semi-stale paper cannot be relied upon to behave in accordance with its description when freshly made.

(4) The measurement of these constants presents difficulties, particularly in regard to total scale and rendering power. It is unlikely that various manufacturers' figures will be comparable.

(5) There is danger that competitive advertising will impair the accuracy of any measurements.

An Alternative Scheme.

Let us consider whether there is any alternative scheme which will do away with the necessity of publishing the emulsion constants. A finished print owes its appearance to the collective action of the emulsion properties, of which the more important have been described in this paper. Prints upon different papers from the same test negative would indicate by their similarity in general appearance that for practical print production the papers had similar properties. On the other hand, marked dissimilarity between the prints would indicate that one or more of the emulsion constants of one paper differed from those of another. It might be possible for manufacturers to adopt about six standards of contrast, ranging from the present-day vigorous gaslight paper standard to that of a soft bromide paper. Using a test negative kept for the purpose, a set of prints illustrating each of these broad contrast classifications would enable further batches of paper to be classified by visual comparison. The eye is able to judge print differences and print similarities tolerably well when the prints compared are of the same size and the same depth and are made from the same negative. The six degrees of contrast could be labelled by the manufacturer in an appropriate manner (A to F or 1 to 6), so that the user could order a similar stock of paper by quoting the maker's classification. Such a scheme is, of course, merely an advance in point of fine classification over the present system of descriptive words, viz., hard and soft, etc.

I am not in the position to venture an opinion as to the feasibility of this alternative scheme or otherwise. If it be a fact that the present-day manufacture of developing out papers is so advanced in control that manufacturers can turn out papers of different degrees of contrast at will, then there should be no difficulty in adopting a scheme of classification similar to the one described, to the material advantage of photographers. The effect of age upon the classification would remain a disability and various makers would probably have different standards and classification marks. In the course of time, however, the big user might learn that Messrs. X's paper classified as 3 was equivalent to Messrs. Y's paper classified as B, and so on. If, on the other hand, the degree of contrast exhibited by an emulsion be not completely under the manufacturer's control, then difficulties are apparent at once. If, for example, a manufacturer supplies a paper, and subsequently fails to repeat the manufacturing conditions with sufficient exactitude to renew that emulsion, there will be immediate dissatisfaction with the scheme. An admission of inability to repeat a paper whenever required would be exceedingly damaging to any firm that adopted a policy so honest. It must be confessed that the ignorance displayed by the average photographer concerning the fundamental properties of the materials at his disposal practically compels manufacturers to describe their products in the way that photographers find most pleasing, whether that description be strictly truthful or not. It would be futile to consider any scheme of contrast rating without bearing in mind the possibility of false description. The well-known mis-statements of H. and D. speed numbers in the case of plates are an eloquent object-lesson in this respect.

There is a remaining point of considerable importance. As the development of a paper proceeds there is an increase in gamma, an increase in the black attained, and a decrease in the total scale. When gamma infinity is reached by a sufficiently full development, these measurements reach their final values and remain constant during further development. Whatever the manufacturer publishes, whether emulsion constants or a classification mark, the information should be that obtained by development to the gamma infinity of the paper. It is an unfortunate fact that few workers develop bromide paper to gamma infinity, and few who attempt to do so are frequently deceived when unexpectedly they obtain a batch of paper particularly slow in development. In order that the makers' classification should bear fruit in practice, it is essential for photographers to develop their prints fully. I have indicated elsewhere that factorial development enables this to be done with certainty, but this method appears to remain neglected, particularly by professional photographers. It appears to me, therefore, that it will be necessary for paper manufacturers to give some indication as to whether the user is dealing with a paper of quick or slow developing properties, in order that the under-development of the latter type may be avoided, and so that the paper may yield a finished print in accordance with its specification.

B. T. J. Glover.

Change of Business Name.—Mrs. Beatrice Cundy, of 12 (late 6), Baker Street, Portman Square, London, W.1, writes:—"Owing to family reasons, as from March 7, 1922, I am closing down the business which has been run in my maiden name of Lena Connell. After that date I intend professionally specialising in at-home portraiture in my married name, Beatrice Cundy. Sittings can still be arranged for, and particulars given at the above address."

DEATH OF MR. ALEXANDER COWAN.

We greatly regret to record the death on March 3, in his eighty-sixth year, of Mr. Alexander Cowan, one of the veterans of photography, and for many years head of Messrs. Marion's dry-plate factory at New Southgate. Mr. Cowan, who had been living in retirement for some years past, first at Wembley and latterly at Letchworth, preserved remarkable mental and physical vitality. He had exceeded the age of seventy by some years when he retired from the active supervision of the manufacture of plates and papers for Messrs. Marion, with which he had been associated from almost the outset of the dry-plate process. Yet at that time he had the appearance and activity of a man in the mid-fifties. Throughout his career, Mr. Cowan made and published many contributions to the technical processes of photography. In the early days of the dry-plate process, when methods and formulæ were the subject of

Alexander Cowan

free discussion, he was among the leading experimenters by whom the common stock of knowledge was enriched. And his mechanical aptitude was evidenced in the design of many appliances for adapting the practice of photography to the different conditions imposed by the change from wet collodion to dry plates. We believe that he was among the first in this country to see the possibilities in a self-toning paper, and that he made emulsion paper answering to this description. His death removes one of those who have witnessed the development of photography to its present industrial importance, and have taken an important share in that development. Before joining Marions Mr. Cowan was for many years manager of Hills & Saunders' studio at Porchester Terrace; he was a first class portraitist. In his early youth he was engaged at Paul Pretsch's photo-galvanographic works at Holloway.

Photographs in Guide-Books.—Last Monday's "Times" contained a pithy leaderette on the truthfulness of pictures in guide-books, publications in which "ever truthful" photographs are not employed to the extent they deserve to be. "A truthful guide-book, if it could circumvent the vigilance of the local mayor and corporation and the hotel-keepers, would be an invaluable compilation. Too often (said the writer) it is, at its truthfullest, only a compromise, as when a place is said to 'cater for all tastes.' Illustrators, again, whose skilful brushes adorn the pages of many a guide-book, are apt, through a fault presumably of the artistic temperament, to mislead as much as the writers. Only once do we remember having seen in a guide-book the picture of a town on a wet day. The artist could depict rain very well, and that was, perhaps, why he did it; but he did not do it so beguilingly as to create an illusion in favour of a wet day at that particular town; yet the idea is suggestive, and if it were consistently carried out, as the obverse of the fine weather picture, it would help us materially to make up our minds before setting out."

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Report of the Council.

Your Council are gratified to record that during the year 1921 the influx of new subscribers has been fully maintained—126 being an advance upon the past average. Resignations have been few, and in most cases were attributed to unavoidable causes.

The year has been productive of pronounced advancement in up-to-date methods and policy, culminating :—

(1) In a change of date and headquarters of the 1922 Congress.

(2) In the important steps taken by your Council in regard to the incorporation of the Association, and it is satisfactory to note the unanimity that prevailed when the whole scheme was laid before the members at the Special General Meeting held December 1, when it was moved and carried unanimously "that the Council of the Association do continue and act upon the resolution passed at the Annual General Meeting held April 22 (Congress week)" etc., etc.

Incorporation has proved a tiresome and tedious procedure, but owing to the patience and skill of the honorary solicitor (Mr. Reginald Vaughan of the firm of Stone's Morris and Stone), the registration of the Association is now an accomplished fact.

The 7th Congress was held April 18-22, and though the whole of the arrangements were made during the time of strikes and the uncomfortable threat of a general railway stoppage, everything fixed was successfully carried out.

The programme of lectures and demonstrations, covering a wide range of subjects, was a full one. The contributors included : Mr. H. W. Bennett, F.R.P.S., Madame Yevonde, Mr. N. E. Luboshey, Mr. C. P. Crowther, F.R.P.S., Mr. A. C. Braham (Autotype Co.), and Mr. S. H. Greenway.

The visit to the Guildhall, the Courts and Museum, and the kindly welcome extended by Sir Louis Alfred Newton on behalf of the Rt. Hon. the Lord Mayor, was characteristic of the world-famed hospitality of the City of London Corporation, and was greatly appreciated by the visitors.

The invitation extended by Sir William Jury to witness at his private theatre a demonstration of Prizma motion colour photography was largely attended.

A special feature of the week's entertainments was the invitation visit to the works of Kodak, Limited, at Harrow. The plans made were at the last moment upset (owing to Government restrictions) and the railway company telegraphed their inability to fulfil the contract with Messrs. Kodak to supply a special train, but with commendable promptitude a fleet of motor char-a-bancs was obtained and the large party of guests (conveyed to their destination by that means) spent a most interesting and enjoyable afternoon and evening.

The picture exhibition at the Royal Horticultural Hall—designed to illustrate and advertise the present position of professional photography, was another step in advance of former efforts, but owing to the lack of wall space it was only possible to accommodate a limited number of the pictures sent in. There was a notable increase of technical and commercial exhibits.

A happy termination of the Congress proceedings was the annual dinner, held at Gatti's Restaurant, Strand, on the evening of Friday, 22nd, when a large company assembled to do honour to the outgoing and incoming presidents—Messrs. Frank Brown, Leicester, and A. Swan Watson, Edinburgh.

The 1922 Congress is arranged to take place at Princes Galleries, Piccadilly, W., September 11-15 inclusive.

Your Council have pleasure in referring to the visit paid in July to America by Mr. Reginald Haines, who, at his own expense, represented this Association at the Buffalo Photographic Convention, where he was most kindly received and officially welcomed. At the October meeting of the Council Mr. Haines described his experiences, and announced that the happy thought of presenting in the name of the P.P.A. a miniature replica of the British national flag was received with great enthusiasm, and added that it was immediately decided to return the compliment.

On the evening of September 14 the Council entertained to dinner the world-renowned men's photographer, Mr. Pirie MacDonald, of New York. The opportunity was taken by the guest to convey in glowing terms the appreciation felt by the American photographers of the brotherly message of goodwill brought to them from England by Mr. Haines. Mr. Macdonald expressed the opinion that a bond of fellowship was now established that would be good and useful to both countries.

It is in sad remembrance that the death of Mr. S. H. Fry has to be recorded. He passed away on July 8. One of the first subscribing

members, he lived to do good work for the P.P.A.; was many years a member of the Council, and filled the posts of honorary treasurer, secretary and trustee. At the invitation of the Council Mr. George Hana accepted the vacant trusteeship.

The advantages in the reduction of premiums offered by the British Dominions Fire Co. have been largely accepted—the sum represented being £41,844. The probable stocking of celluloid flat films and the attitude to be adopted towards members by this Company, have been fully discussed in conference, and a satisfactory understanding come to, whereby no extra premium will be charged.

After a series of deputations and discussions with the Westminster Electric Light Co your Council have been successful in obtaining a reduced rate of 4d. per unit for studio arc lamps and special lighting equipment.

At the request for professional portrait exhibits by the Canadian Government, your Council authorised the Sub-Committee to collect and send some pictures to the Vancouver Exhibition. A collection was forwarded and much appreciated, and it is pleasing to note that two of our members, viz., Messrs. Herbert Lambert and William Crooke, were each awarded a silver cup. Exhibits were also forwarded to the South African and Copenhagen Exhibitions.

It is gratifying to record that cordial relations are still maintained between ourselves and kindred societies in other lands.

In the course of the year your Council has dealt with requests for guidance and advice upon a wide range of professional subjects, including:—Damage of goods by rail and post; Rent Restrictions Act; assistants' wages; early closing; ancient lights; visits of travelling photographers to a town, and how to frustrate their methods; income tax; exchange and sale; apprenticeship; difficulties with the Press; infringement of copyright; employers' liability; ownership of negatives; general insurance, etc.

Many letters of thanks, and in some cases thank-offerings, have been received.

Two cases were of outstanding interest, clearly illustrating the influence of the Association when used in support of a member:—

(1) The premises of a country member were burnt out, but the settlement of the claim was held up owing to a disagreement between the opposing fire assessors over the amount to be allowed for salvage. The aid of the Association was sought, and a meeting of the parties was arranged in London, resulting in a satisfactory settlement of the dispute.

(2) Early in September a member complained that after his camera had been placed in the luggage van of a Great Western train, he was charged for its transit, and was unsuccessful in getting the money refunded. The matter was laid before the Council, and the General Manager written to, and on September 28 a deputation waited upon him at Paddington Station. After some discussion a promise was given that the matter should have consideration. It has since transpired that cameras carried as personal luggage will not be charged for.

The scale of Press minimum reproduction fees arranged and fixed by your Association is working satisfactorily. A copy of the agreed scale may be obtained by application to the secretary.

The attendance record is as follows—the number of Council meetings held being 11, and Finance meetings 11.

The thanks of the Association are hereby tendered to the editors of the "British Journal of Photography," "Amateur Photographer," Houghton's "Bulletin," the "Photographic Dealer," and the Kodak "Professional Photographer," for publishing reports and helpful reference to the Association's work. The Council also desires to place on record its thanks to Mr. Reginald Vaughan, the honorary solicitor, for his continued assistance and guidance

On behalf of the Council,

LANG SIMS,
Secretary.

ROYAL PHOTOGRAPHIC SOCIETY.

THE NEW PRESIDENT.

IN electing to the Presidency of the Society Mr. W. L. F. Wastell, the members have paid a deserved tribute to one who has identified himself with the practice of photography for many years, and by contributions, which for the most part have been anonymous, has done a very great deal to promote a sound knowledge of photographic technique. These writings of Mr. Wastell's are thus much

Portrait by] [*George Hawkings.*

MR. W. L. F. WASTELL,
Elected President of the Royal Photographic Society, March 14, 1922.

less widely known than the weekly page of humour, often embodying much sound sense, which for nineteen years past he has written in "Photography," now the "Amateur Photographer." As the author of "Piffle" "The Walrus" has become a celebrity, enjoying the affections of photographers to a degree which is certainly not equalled by any of those whose work for the photographic press has dealt with the severe technics of the subject, or even in the endless discussions of pictorial questions. These chapters of wit and nonsense now number nearly 1,000. Some day, perhaps, Mr. Wastell may collect them in book form, endowing the craft, so to speak, with a comic history of photography in the style of Gilbert à Beckett. To what extent he will be able to import a humorous flavour at Russell Square into discussions of halide grains or gamma infinity remains to be seen, but we have our hopes for the best. By profession a school-master, whose scholastic work has been chiefly in mathematics and English, Mr. Wastell brings to the affairs of the Royal a trained and logical mind, and we have confidence that under his guidance the Society will progress on sound lines. His photographic interests are broad, and, outside photography, his amateur pursuits include water-colour painting, the violin, wood-working, books, and, as we have heard him remark, influenza in all its varieties.

MESSRS. J. H. DALLMEYER, LTD., are issuing an attractive shelf slip to dealers. The words "Insist on a Dallmeyer Lens" appear in white ivory-like letters on an imitation red plush ground.

Exhibitions.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The twenty-seventh annual exhibition of the society was opened last week at the South London Art Gallery, Peckham, and will remain open until the 25th inst. Although called the twenty-seventh annual exhibition it is eight years since the last one was held. The society, which is now one of the foremost in London, has been famous for its exhibitions for many years, and their revival is an event of some considerable importance.

Mr. C. Pollard Crowther gave on the opening evening an entertaining lecture on "Portraiture and Colour," the exhibition being officially opened by Dr. G. H. Rodman, President of the Royal Photographic Society. Dr. Rodman, in declaring the exhibition open, said he was very pleased with the high standard of work. He was also pleased to see the South London Society resuscitated after a lapse of some years, and it was more pleasing to know that it was affiliated with the Royal Photographic Society since 1889—which meant that it was about the oldest society affiliated with the parent body. South London always had a reputation for good exhibitions—exhibitions that commanded a deal of attention generally, and he congratulated the members on their progress.

Mr. Bertram Cox acted as judge, and made the following awards:—Class A.: Bronze Plaque, Herbert Lambert; Bronze Medals, Hugo van Wadenoynen and J. Arthur Lomax; Hon. Mention, H. W. Stowe, Herbert Felton, Miss Dora Head, Harry Abbott, junior, M. O. Dell and W. R. Fernley. Class B: Bronze Plaque, C. J. Unsworth; Hon. Mention, E. Tinker, W. Selfe, Louis J. Steele, H. Pickwell, Harry Abbott, junior, A. O. Forder, C. W. Colthrup and Herbert Felton. Class C: Bronze Plaque, C. W. Colthrup; Hon. Mention, Captain J. W. Bamfylde. Class D: (Members only), Bronze Plaque, W. B. Ashmole; Hon. Mention, Harry Abbott, junior, W. H. Howard, Herbert Pickwell, L. Clampch, Mrs. C. Nunn. Class E: (Members only), Bronze Plaque, Harry Abbott, junior, for the subject "The Monkey"; Bronze Medal, Captain J. H. Jennings, "Victorian Memorial"; Hon Mention, R. C. Snell and E. R. Bull.

The collection of pictures on loan, and not for competition, includes some excellent studies in child life by Mr. Marcus Adams, and a series of landscapes, of perfect pictorial and technical qualities, by Mr. Arthur C. Banfield

FORTHCOMING EXHIBITIONS

March 4 to 25.—South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Peaoval Road, East Dulwich London, S.E.22

March 15 to 26.—Welsh Salon of Photography. Particulars from the Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

March 16 to 18.—Leytonstone and Wanstead Camera Club. Particulars from the Secretary, Charles Wormald, 1, Colworth Road, Leytonstone, London, E.11

March 27 to April 8.—Dennistoun Amateur Photographic Association. Particulars from the Exhibition Secretary, Colin Graham, 448 Duke Street, Dennistoun, Glasgow.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E 5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Latest date for entries, March 22 Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 5 to 8.—Faversham Institute Photographic Society Latest date for entries, March 31. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair Horticultural Hall, Westminster Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patent applications and specifications—are treated in "Photo-Mechanical Notes."

Applications February 27 to March 4:—

Developing Tank.—No. 5,971. Tank for developing and fixing photographic films. Amalgamated Photographic Manufacturers, Ltd., and M. Rycott

Colour Photography.—No. 6,099. Apparatus for reproduction on paper of Autochrome, etc., plates in colours. E. Bueno.

Colour Photography.—No. 6,253. Colour photography. Sir C. S. Forbes.

Developing Apparatus.—No. 6,292. Apparatus for developing photographic films. L. M. Ellis.

Printing Apparatus.—No. 6,115. Photographic printing apparatus.—J. Evans

Finishing Prints.—No. 5,785. Production and finishing of photographic prints. G. E. Hadley.

Colour Photography.—No. 6,291. Apparatus for multi-colour photography. J. Mroz

Reversal Processes.—No. 5,873. Photographic reversal processes. Kodak, Ltd

Photographing Sound Waves.—No. 5,960. Production of sound-wave photograms. R. Mylo.

Cinematography.—No. 6,471. Projection of moving pictures. Bardy Motion Picture Machine Co.

Cinematography.—No. 6,325. Automatic picture projection. W. C. Chamberlain.

Cinematography.—No. 6,408. Records for cinematography. W. Gowlland.

Cinematography.—No. 6,11b. Cinematographic screens. A. V. F. Marion.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention

Metallic Lantern Screens.—No. 174,957 (May 17, 1921). This invention relates to opaque screens for use in connection with cinematograph lanterns and like projection apparatus, of the kind having a metallic surface formed of powdered aluminium, silver, bronze, etc. The invention consists in an opaque screen having a metallic surface formed of powdered aluminium or the like upon a coloured background and matted by means of barium sulphate.

The object of the invention is to make such screens capable of producing a colour effect instead of the usual black and white effect produced by the present screens of this type, and to reduce as far as possible the shadow effect which is rather pronounced with metallic or metalised screens when viewed from acute angles and to obtain an even diffusion of light at all angles of observation. Whilst any colours except black and white may be used, the colours preferably used are orange, or red, as being most suitable for general use. Green and blue backgrounds may be suitable for reproduction of wooded and like scenery and of seascapes.

Whilst the metalised surface of the screen has generally the effect of reflecting the light and of producing a very clear reproduction of fine detail, the coloured background has the effect of giving a certain tone to the picture.

For reducing the shadow effect and for matting the brilliant metallic surface barium sulphate is used as a final coating, which is applied to the metallic coating. The barium sulphate may also be mixed with the metallic powder.

The coloured background for the metallic surface may be produced in any suitable manner, but it is preferred to prepare this background in such a manner as to enable the metallic surface to be formed thereon in the usual manner.

A screen embodying the features of the invention may be prepared in the following manner. A canvas or cotton fabric in one seamless sheet is prepared in the usual way for painting. One or more coats of paint containing each white lead, red lead (or orange powder or other colouring matter), genuine linseed oil and liquid dryers, are then applied either by means of a brush or of a hand-spraying machine. If hand-painting is used the surface should be carefully stippled. A final coat is then applied which contains, in addition to the above-mentioned ingredients, heavy stand oil. A metallic powder, for instance aluminium powder, is then thrown by hand upon the final coating, which should be in a suitable condition, *i.e.*, nearly dry, but should have sufficient tackiness to hold the powder. The metallic powder is gently brushed all over the surface and is finally, after a suitable interval, brushed off. The powder may, of course, be applied in any other suitable manner, for instance, it may be sprayed on. The sheet is then sprayed with a mixture of highly refined barium sulphate and glue dissolved in water. Instead of spraying the barium sulphate on to the aluminium, the barium sulphate may be mixed with the aluminium.

The combination of a coloured background with a metallic surface consisting of powdered metal and matted by means of barium sulphate is the main feature of the invention, the object of the coloured background being to soften the hard effect produced by the metallic surface and to give a definite tone to the picture. —Julian Macartney Ogilvie, 24, Nevern Square, Earls Court, London.

The following complete specifications are open to public inspection before acceptance :—

Cinematography.—No. 175,968. Motion-picture projection apparatus. Pathé Cinema Anciens Etablissements Pathé Frères.

Image Transforming Method.—No. 175,988. Method of transforming photographic silver images into tanned gelatine images. P. Schrott.

Shutters.—No. 175,991. Photographic shutters. A. Wollensak and F. A. G. Pirwitz.

Photographing Mount Everest.—Describing the preparations for this year's Mount Everest Expedition "The Times" gives the name of Capt. J. B. L. Noel, M.G.C., as the photographic officer, and says that the photographic outfit is very complete. The apparatus includes three cinematograph cameras, of which one is equipped with a battery of lenses up to 20-in. focal length; two panoramic cameras, of which one rotates through the complete circle; four cameras for glass plates, including one 7½ in. by 5 in., all fitted with telephoto lenses; one stereoscopic camera, and five Kodaks, besides a variety of private cameras belonging to different members of the party. The dark-room equipment includes all that is required for developing cinematograph films in the field.

The American Rush for Royal Wedding Pictures.—The "Star" gives further details of the extraordinary scrimmage for films and prints of the Royal wedding. It is stated that when the "Olympic" reached New York she was besieged by a horde of photographers' assistants trying to secure the photographs which were in charge of the purser. Eight tugs lined up alongside the ship the moment she dropped anchor, and as soon as the liner was cleared by the doctors the photographers scrambled aboard and charged for the purser's room. There was a howl of dismay when the purser announced that he could not deliver the films until the ship had docked. Pleas and protests were unavailing until a committee of the photographers sought out Captain Hambleton, who gave instructions to the purser to hand over the pictures to those having orders to receive them. Then another merry battle ensued, the photographers' assistants rushing back to the dock, knocking passengers right and left in their frantic efforts to save precious minutes. One man had his films in a waterproof cylinder, to which several toy balloons were attached, in order to give the cylinder buoyancy.

THE ROYAL PHOTOGRAPHIC SOCIETY.

The annual general meeting held on Tuesday evening last, with the President, Dr. G. H. Rodman, in the chair, was opened by a discussion as to whether smoking should be allowed at the meetings. The conclusion arrived at was to allow smoking at any meeting except those at which lantern slides were to be shown. The President then suggested that the report of the Council should be taken as read and discussed paragraph by paragraph.

One member very kindly suggested that the salaries of the secretary and his staff should be increased, but as there was a slight deficit on the balance-sheet, owing to a large number of members having not paid their subscriptions, this suggestion was said to be rather difficult to carry out.

It is gratifying to note from the report that the Journal is now being published in eleven monthly issues instead of eight, and that the advertising department has been transferred to the Society's

house. Many thanks are due to Mr. George E. Brown for his many valuable suggestions and advice.

With regard to the annual Exhibition, it was announced that it was hoped to have an improved method for showing lantern slides and Autochromes at the next Exhibition.

A vote of thanks was passed to Miss M. Talbot for the addition of many interesting pieces of apparatus to the Fox-Talbot collection. Referring to the Fox-Talbot Memorial, Dr. Rodman said that he thought it might take the form of a lecture or scholarship open to members of the Society, and that further contributions would still be very welcome.

A very valuable contribution to students of photography has been the production by the Scientific and Technical Group of "Photographic Abstracts," under the able editorship of Mr. B. V. Storr, M.S.C., F.I.C.

The Pictorial Group which was formed during the year is also going strong.

Votes of thanks to the officers and staff followed, and Mr. J. B. Portway then read the report of the scrutineers of the ballot for the election of members, which had resulted as follows:—

President

Mr. W. L. F. Wastell.

Vice-Presidents.

Mr. J. Dudley Johnston.
Mr. F. F. Renwick, F.I.C., F.C.S

Hon. Treasurer.

Mr. E. W. Mellor, F.R.G.S.

Ordinary Members of Council

Marcus Adams	Thomas Illingworth, J.P.
A. C. Banfield	Ernest Marriage.
A. J. Ball.	F. Martin-Duncan, F.R.M.S.
Capt. D. Cameron-Swan, F.S.A.	C. H. Oakden, F.R.M.S.
G. Bellamy Clifton.	T. Slater Price, D.Sc., F.I.C.
Bertram Cox.	T. H. B. Scott.
C. Pollard Crowther.	W. F. Slater, F.R.G.S.
W. B. Ferguson, K.C., F.I.C., M.A.	J. C. Warburg.
G. I. Higson, D.Sc., F.I.C.	G. C. Weston.

The retiring president, Dr. G. H. Rodman, then introduced the new president, Mr. W. L. F. Wastell. As Mr. Wastell is a well known member of the Society, he did not, as Dr. Rodman said, require any introduction to the Society. Mr. Wastell then called upon Mr. T. H. B. Scott to propose, and Mr. G. C. Weston to second, a vote of thanks to the scrutineers, which was carried unanimously. Messrs. Calder, Marshall and Ibotson were re-appointed auditors, and are to receive an honorarium of eight guineas instead of five for their services, and with this business the president declared the meeting closed.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on Monday, March 6. Present: Mrs. MacKay, Miss Bertram, and Messrs. J. Campbell Harper, John Thomson, E. D. Young, William Fergusson, W. B. Hislop, George Balmain, W. J. Hutcheson, P. S. Moffat, Aikman, Johnston, Bambrick, and Swan Watson. Mr. J. Campbell Harper (President) in the chair.

The meeting unanimously appointed Messrs. Balmain and Fergusson as members of the Committee to conduct Class Examination at the College of Art. The Secretary read a letter from Mr. George J. Hughes, photographer, of Bridge-of-Allan, requesting to know if he would be eligible for membership of the Society. It was pointed out that by the present constitution he was not eligible for membership, but the Society would be delighted to admit him as a member as soon as the constitution was altered at a general meeting to be held in May.

Mr. Swan Watson reported the result of his visit to the College of Art, and gave the impressions he had received from his visit there. In his opinion the training which the pupils were receiving at the hands of Mr. E. D. Young was excellent. Mr. Campbell Harper also expressed himself as being favourably impressed by his visit to the College, and spoke of the benefits which the pupils were receiving from the tuition at these classes, giving as an example work done by an assistant the previous week. A photograph of a gentleman, deceased, was brought in for enlarging, with alterations. The original photograph showed the gentleman with a hat on and in shirt sleeves, in a garden. A copy negative was made, the hat blocked out and a small enlargement made, and from another snap showing the hair, the assistant drew on the hair, and put a coat on, the result being most successful. This young assistant had less than two winters at Mr. Young's drawing and retouching classes.

A long discussion then took place as to the desirability of holding a Congress and extending the membership. Several members gave their views on the matter, and ultimately it was resolved to extend the membership to those carrying on business in the country, and that when the constitution of the Society fell to be altered a rule would be added accordingly, whereby the area would be extended and country members admitted to the Society. It was resolved to take the opinion of the Glasgow Society on this matter, and Messrs. Harper and Young were appointed to go to Glasgow on an early date and discuss the whole matter with the Society there.

With regard to holding a Congress, Mr. Moffat stated that the idea was that a hall should be rented where an exhibition of professional work would be held. Photographers would also be able to take space and show their work separately. Several of the large dealers had intimated their intention of taking stands. The question was discussed as to the exclusion of amateurs from the lectures and demonstrations, and the general opinion of the meeting was that these should be only for members of the Congress, who would be admitted on showing their badges. Further information was necessary, however, before the Society could decide as to how the Congress should run, and it was resolved to continue the discussion at a subsequent meeting.

News and Notes.

Portraits on Travellers' Advices.—A writer in one of the evening papers says that travellers' advices should not be complete without a photograph depicting "our representative who will have the pleasure of calling on you."

Press Photographers' Wages.—A Trade Union newspaper states that negotiations are in progress with the Press Photographers Proprietors' Association for a new agreement, that the situation is not satisfactory, and "unless a more conciliatory spirit is manifested a serious situation may shortly arise."

Photography in Washington Museum.—We learn from our American contemporaries that the National Museum at Washington has one large and well filled room devoted to the history and progress of photography. Here the interested visitor may find a little of anything and everything photographic; old Daguerreotypes, plain silver, carbon, platinum and other prints, apparatus such as is never dreamed of to-day, motion picture machines, early methods of cameras and apparatus, modern pictorial work, airplane cameras, process cameras and lenses, colour photographic exhibits, etc. Fine as the collection is, however, it is not complete; there are gaps in the line of exhibits, and an appeal for more photographic material is being made.

Photographs in Old World Cottage Decoration.—Writing on the furnishing of thatched old-world cottages, a writer in the "Daily Chronicle" says:—"Photographs should never hang upon the walls of an old world cottage. Some people cling to examples of the photographic art and like portraits 'about them,' but they look out of place amidst old china and pictures. A woman with exquisite taste for furniture combined with sentimental leanings towards photographs of relations and friends solved the problem in quite a novel way. She had all photographs in standing frames and kept them in a bureau drawer. Each day she put one out, substituting it for that which had looked upon the world the day before. In this way they were all given the honour of gracing her small and well polished occasional table. Another woman revived the old fashioned album beautifully disguised in modern tooled leather, and all photographs were kept in this volume."

Exhibition at Morley.—The Morley Amateur Photographic Society having been given an oxydised silver shield by the residents of the town to be competed for annually, the council, at a special meeting held on March 9, decided to hold an exhibition and competition which will be open to all amateur photographers who are residents in England, Scotland and Wales, from April 22 to 29 next, when the following prizes will be given:—The shield,

which is to be held by the winner for twelve months and then returned to the society, also a silver oxydised medal and £1; a second price of 15s.; and a third prize of ten shillings. The judges for the competition will be Mr. Harold G. Grainger, of Leeds, and Mr. Harold A. Crawford, president of the Leeds Photographic Society. The latest closing date for entries will be April 14 next. Entry forms and particulars may be had from Mr. R. Spence, 26, South Queen Street, Morley, near Leeds.

IMPROVING CAMERA CASES.

To the Editors.

Gentlemen,—In reply to Mr. T. P. MacNally, allow me to say that the Thornton-Pickard Company studded both the case and the reflex camera supplied to me. The case, which is of the attaché pattern, besides having good-sized studs on the bottom, is also studded at this side. The camera base is also treated in a like manner. It is a splendid idea which I have very often appreciated.—Yours faithfully,

W. J. Wray.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. R.—We have never heard that the big shipping companies have photographic service on their vessels.

W. H.—The screens are made by Kodak, Ltd. (Wratten Division), Kingsway, London, W.C.2, who will send you, on request, a booklet describing them.

P. G. J.—Any good ready-made distemper is suitable, or you can use the Vanguard "Kalko" background paint, which is made in black, white and grey.

V. J.—Providing films are carefully handled, that is, not rubbed against one another, a waterproof ink is fairly satisfactory, as is also a copying-ink pencil.

L. E. D.—The reports are at the moment a little confusing owing to rivalry of establishments issuing them. Some time must elapse before the matter can be definitely decided.

B. J.—We are unable to name a firm undertaking the special work you require, but would suggest that you apply to Messrs. Jeffery and Boarder, 55-56, Mattock Lane, Ealing, London, W.13, who may be able to help you.

B. J. B.—We think it would require a lawyer of experience in corporation law to answer your question. You must not put much value on our opinion, which, however, is that it is extremely doubtful if you can claim any compensation in respect to the publication of your first offer.

C. H.—We can suggest no use for the spoilt cards. Damp gaslight cards may often be made to give a passable print after warming well before exposure, either before a fire (the cards being kept in their original packets) or by placing each card on a hot water bottle in the dark-room.

T. R. F.—The standard book on the subject is "Ferric and Heliographic Processes," by George E. Brown, which is out of print, but you could possibly obtain a copy from Messrs. Foyle, 121-123, Charing Cross Road, W.C.2. The true-to-scale gelatine process (with several others) is fully described in the "British Journal" for July 19, 1918. Our publishers can supply this issue on receipt of 5d. in stamps.

C. B. E.—Yes, if you do not trade under your own name you are required by the Registration of Business Names Act to register your business. The office of the Registrar is at 4, Clement's Inn, Strand, London, W.C.2. The cost of registration is 10s. Under the Act you have to put your true name on "all essential business stationery," but you do not require to put your name on mounts of photographs nor to display it in or about your place of business.

G. H. E.—We suggest that you write, stating your requirements, to our agents in Japan, Messrs. Maruzen Co., Ltd., 11-16, Nihonbashi Tori Sanchome, Tokyo. We have no doubt that they would be able to pass on your letter to a firm of the kind you are seeking. We suppose you wish to get in contact with a wholesale firm supplying photographs and mounts to photographers in Japan. But that is by no means clear from your letter. In writing to our agents, who read English perfectly, you should be more explicit.

N. R. D.—The sulphide solution has nothing to do with the spots upon your cards. On examining the bleached prints with a magnifier they were plainly visible. The card "A" was then treated with sulphide solution one-third the strength you used, and that marked "B" was redeveloped to black with amidol. This was very much worse than the toned picture. Both are worse than the toned cards you sent. If you find that your black and white cards are free from spots we should attribute the trouble to hypo dust coming in contact with the prints between bleaching and sulphiding. If the black and white ones are spotted then the fault is probably due to the cards having been spoiled by damp.

D. A.—It is rather difficult to give an exact formula for distemper, as the quality of the materials has an influence on the consistency. An average would be two balls of whiting dissolved in about half a gallon of water; when quite smooth squeeze in a little laundry blue until the mixture has a pale blue tint, then add 1 lb. of double size dissolved in an old saucepan. Stir vigorously, and leave till quite cold. The mixture works much better if left till partly decomposed; that is to say, when it has a decidedly unpleasant odour. An easier way is to use the Vanguard Company's white "Kalko" background paint, which only wants mixing with cold water. We can say from experience that this does not rub off.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3229. Vol. LXIX. FRIDAY, MARCH 24, 1922. Price Fourpence.

Contents.

SUMMARY.

A contributed article by Mr. Mervyn Thompson outlines a competition scheme as a suggested means of reviving business in portraits in a given town if it is possible to secure collaboration of other trading firms. (P. 167.)

Working instructions for providing a studio or reception room with a wall covering, which forms an effective substitute for oak panelling, are given by a contributor to "Assistants' Notes." (P. 172.)

At the annual general meeting of the Professional Photographers' Association it was stated that the September Congress will, in all probability, be attended by Mr. Pirie Macdonald and by Mr. J. C. Abel, secretary of the American Association of Photographers. (P. 177.)

When the copyright in a photograph has been infringed, it is not a good defence for the infringer to say that he thought the copyright belonged to somebody else; according to the Act the admissible plea is that he had no reason to suspect there was any copyright at all in the photograph. (P. 166.)

Enlargement of part of the negative, so frequently done in the case of landscapes, often has its advantages in the case of portraits. (P. 166.)

In the production of booklets setting forth the attractions of hotels in pleasure and health resorts special care in the photography and in the letterpress printing will make an immense difference in the business value of the prospectuses. (P. 165.)

In a leading article we deal with the causes of the chief descriptions of spots which are liable to occur through faulty manipulation of bromide paper. (P. 166.)

Mr. Edgar H. Booth, B.Sc., in an article in the "Australian Photo-Review," gives a formula for a concentrated one-solution metol-hydroquinone developer, which has been found very satisfactory for plates, papers and lantern-slides. (P. 168.)

Mr. J. I. Crabtree, in a further portion of his paper on the testing of developers, deals with the comparison of developers as regards fog, keeping qualities and colour of image. (P. 170.)

At the Royal Photographic Society on Tuesday evening last it was announced that Mr. E. F. Renwick, who for many years has been chief scientific chemist for the Ilford Company, is leaving for America in the course of next month, and is joining the Du Pont de Nemours Company. (P. 176.)

Professor Namias has recommended formulæ in modification of the Ferguson process of copper toning by which prints of brown or warm-black tone are obtained. (P. 165.)

A correspondent calls attention to a peculiarity in the action of the permanganate reducer (P. 179.)

EX CATHEDRA.

Modified Copper Toning. Some variations in the customary Ferguson process of copper toning are recommended by Professor R. Namias, of Milan, an experimenter whose modifications of various existing methods reach quite a respectable total. The prints are first toned in the usual bath of copper sulphate, potass ferrocyanide and soda citrate, but Namias lays especial stress on the purity of the last-named. The citrate should not be alkaline, as some samples are, and, on the other hand, if too acid, causes the toning bath to become muddy sooner than it should. One variation, or rather extension, of the process is to transfer in full daylight the fully toned and washed prints to a metol-hydroquinone developer containing 2 gms. of bromide per litre. The silver ferrocyanide in the toned image is thereby reduced to silver, agreeably modifying the tone. Lightly developed prints should be used, as the process intensifies. A second variation is to treat the copper-toned print with a 1 per cent. solution of caustic potash or soda, the effect of which is stated to be the formation of a violet-coloured oxide of copper in the image. The print is then placed, in full daylight, into a developer, by which again the silver ferrocyanide is reduced, the resulting print being of pleasing brown colour. If the copper toning be carried out partially in the first instance, the resulting tone is a warm black. Unlike the modification already mentioned, the process has not an intensifying effect.

* * *

Hotel Photographs. There is still a good deal to be done by photographers undertaking the supply of photographs for booklets descriptive of hotels in the way of persuading proprietors of the value of creating the best impression upon recipients of the booklet. One has only to write, for example, to half a dozen private or residential hotels in any popular resort in order to obtain a useful demonstration of the effectiveness of good photography allied with good printing in comparison with the unconvincing story told by a booklet in the production of which one or other of these essentials has been neglected. Photographers who have the opportunity of seeking work of this kind will be well advised to make a little collection of good and bad examples. It is astonishing to what extent in many cases a chief attraction of the seaside resort, namely, sunshine, is neglected. No need to think that sunshine needs to figure only in exterior views; the attractiveness of a bedroom or sitting-room shown in a flood of sunlight is something which makes an irresistible appeal to the would-be visitor from the smoke and fog of great cities. Much of the effect of photographs which are attractive in this and other respects is, however, liable to be lost by an unsuitable process of reproduction. The photographer ought to make it his business to persuade the customer of the advantage of letting him take charge of the whole job—printing as well as photography.

Half-tones printed, for example, in brown or sepia, and mounted on thin art papers of appropriate colour, form an illustrated prospectus infinitely more powerful as a bringer of visitors than the same prints reproduced in ordinary printing ink on a white paper. Given ideas of what is effective for the special purposes of the hotel proprietor, photographers will have no difficulty in obtaining appropriate printing from firms such as Messrs. Hood or Walter Pearce & Co., both of whom have made a specialty in the printing of booklets of which photographic reproductions form a large part.

* * *

Selection in Enlarging. The average portraitist often makes negatives which, although defective for some reason, such as careless centring upon the plate or an unnoticed error in posing, are still capable of yielding an artistic result if the offending portion be omitted and the remainder enlarged to such a size as will produce an effective picture. A little extra work may be incurred in doing this, but the photographer who has ideas beyond that of supplying his customer with the requisite number of more or less satisfactory prints, will not grudge this if he can make something better than the other poses of the sitting. Now that we have enlargers which are almost, if not quite, automatic in their action, the extra work is very slight, and the financial result will probably more than justify it. We fear that there is not yet a sufficient recognition of the value of the slow papers which yield warm black tones by simple development when used for enlarging. A strong illuminant is necessary, and fortunately this is available in the small enclosed arc lamps which are made specially for projection. With these, exposures of only a few seconds are necessary with average negatives, the current being taken off the ordinary wiring as used for incandescent lamps.

* * *

Innocent Infringement. The clear provisions respecting copyright, which are a feature of the present Act, have had the result, at any rate so far as photographs are concerned, of very greatly reducing the number of disputes which get as far as proceedings in the courts. Under the Act, the rights and liabilities of two people who may have been brought into conflict are sufficiently clearly defined as to avoid the necessity of the further legal expenses involved in taking the issue before a judge. In the comparatively few cases which have come into the Courts, that is to say, actions taken for infringement of copyright, it is curious to note that the infringer, while alleging his innocence, has almost invariably ignored the provision of the Act by which an innocent infringer is exempt from liability to pay damages, etc. According to Section 8 of the Act, it is a good defence for the infringer to prove that at the date of the infringement he was not aware and had no reasonable ground for suspecting that copyright subsisted in the work, instead of which it usually happens that an infringer puts forward as his defence that he thought the copyright belonged to some person (usually the person from whom he obtained the photograph) other than its real owner. Recently there was a case in an Irish Court in which most lengthy arguments were put forward for the defence on this latter basis, for which, however, there is no support in the Act. It may in fact be said that the loophole provided for the infringer by Section 8 is a very small one. Anyone having any business whatever in the reproduction of photographs may be expected to know that by the taking of the photograph copyright is created as the property of somebody, and that it lasts for a period of 50 years from the taking of the negative. Hence it is scarcely possible, in the case of a photograph of comparatively recent origin, for anyone to entertain the view that there is no copyright in it. The precise terms of Section 8 should be borne in mind by those whose copyrights may be infringed, since the pleas of innocence which are usually put forward fall to bits when examined in terms of the explicit provisions of this section.

SPOTS ON BROMIDE PRINTS.

The degree of mechanical excellence which has been reached in the coating of bromide paper has reduced to a minimum the probability of any spots which may appear upon prints being due to defects in manufacture. While defects in coating may occur occasionally, they usually manifest themselves as streaks or sharp lines, or more rarely as small uncoated patches. Therefore, in the case of small spots or very small irregular markings, we may usually trace the cause to some error in storage or manipulation. As in the case of plates or films, storage in a damp place gives rise to a multitude of small white or grey spots, varying in size from the finest pinhole to an eighth of an inch in diameter. These are more or less irregular in shape and usually unsharp at the edges. In such cases there is no remedy but to discard the remainder of the paper in use, although, if there is a large stock, it is not wise to do so without testing several packages, as one of these may have been in contact with a damp wall or shelf and others may still be in good condition. The trouble in this case is, of course, due to a partial decomposition of the gelatine, and this may arise at a later stage, with paper which is in good condition at the time of exposure, through excessive washing after fixing. This usually occurs in fairly warm weather, and then only when prints have been left in the water all night. It is obvious that in endeavouring to trace the cause of such a defect the prints must be closely scrutinised at intervals, in order to ascertain at what stage of the manipulations it arises. A small pocket magnifier is useful for this purpose, unless the investigator has unusually good eyesight.

Small white or grey spots of a circular or irregular oval outline, with sharply-defined edges, are usually due to tiny bubbles, which have prevented the developer from reaching the surface during a part or the whole of the time of immersion. These are often due to wetting the paper before development with water drawn from a high-pressure source, or by using developer which has been diluted straight from the tap and poured on the print straightway. When using very rough surfaced papers it is advisable to swab the surface with a pad of cotton wool immediately upon immersion in the solution. Development bubbles may be distinguished from bubbles in the emulsion coating by the fact that the latter show a thickened margin and a dull appearance in the centre. If bubbles occur in the fixing stage they will cause no apparent defect in black prints, although they will probably appear in a few weeks. They will, however, speedily manifest themselves as brown spots if the prints are sulphide-toned.

By far the greater number of spots are due to chemical dirt; that is, chemical substances in the wrong place. Amidol has a great knack of getting where it is not wanted, and most red or purplish spots are due to the presence of fine particles disseminated in the dark room while compounding the developer. Hypo is another offender which only makes its presence felt when toning is resorted to. It has been truly said that the dust of the dark room is hypo. If this were generally recognised many of the troubles of photographers would disappear. Taking the case of a sulphide-toned bromide it is easy

to see the havoc which hypo-dust can work. The bleacher almost invariably used contains a large proportion of potassium ferricyanide. This salt, combined with hypo, forms the well-known Farmer's reducer. If a print, wet with ferricyanide solution, is dusted with fine particles of hypo a reducing action is at once set up, and the patches affected either appear as white spots or as a lighter brown than they should be, according to the more or less complete solvent action of the hypo. The same thing occurs when prints hang together in the washing tank after fixing, but then the patches are larger and cannot be called spots. Here, the hypo is carried into the ferricyanide solution, and may not only damage the print which introduced it, but may slightly reduce others which follow. It is practically safe to assume that when toned prints show spots or markings, while black prints are free from them, hypo, in conjunction with the bleacher, is to blame. The trouble is not to be avoided by using any other bleacher than the bromide-ferricyanide formula, as practically all others reduce the silver into a condition in which it is readily attacked by hypo.

Small dark spots which appear only upon immersion in the sulphide solution are usually due to small air bubbles which have prevented proper fixation where they have been adherent.

Small blue spots sometimes appear on sulphide-toned prints; these are caused by particles of iron from the water-pipes re-acting upon the ferricyanide in the bleacher. The remedy is to tie a couple of thicknesses of washleather or close flannel over the nozzle of the tap. It is surprising to see what an amount of solid matter is collected in this simple filter in even a couple of days' ordinary work. Violet spots have been traced to particles of aniline colour distributed in the workroom in the process of sharpening a copying-ink pencil.

Spots arising from what may be called physical rather than chemical causes require little acumen to detect. An excess of retouching medium sometimes attracts and holds particles of dust. If this happens, the spots occupy the same position on every print. More rarely, dust is adherent to the sensitive surface of the paper, and frequently there are loose particles knocking about on the glass bed of the printing box.

A PROPOSAL TO REVIVE TRADE.

"The best laid schemes of men and mice gang aft agley" is an axiom that too often proves true. A scheme, however good, is liable to fail by reason of the miscalculation of one or another factor, or because that elusive quantity, public favour, has failed to respond.

A great London newspaper started an advertising scheme a short while ago, endeavouring to reform and improve upon the ugliness of men's headwear. Having found a design that was considered to be a great improvement, the thing was foisted upon the public, or at least the public was cajoled into adopting it. Much money was spent, the new hat was boomed, but "John Citizen," apart from a mild interest, and a mild amusement at the few brave souls who flaunted the new fashion, would have none of it. The scheme was dropped; it was a failure.

Even well organised enterprise will fail. To ensure success in a venture of this sort it is not only imperative to organise well, but the idea must fill a want, and, moreover, be one that is likely to catch the public fancy.

The scheme as outlined here is one that is intended to stimulate trade generally in any one provincial town; but particularly to help the professional photographer's business. It is a co-operative scheme and requires organising. Unless it is possible to secure enthusiasm, enterprise, and organising ability above the average it were better left alone. Conversely, the proposition is an attractive one, and is considered sound and good by certain city business men whose judgment is valuable, and who should be competent to give at least a sound commercial opinion.

Briefly, the scheme is a beauty, or bonnie baby, competition, that aims at gaining public favour and support by awarding prizes of such magnitude as to grip the interest and enthusiasm of the whole population. No one industry, confined in one particular provincial town, could afford to give a large sum of money in respect of prizes, particularly the photographic. It is therefore proposed to originate such an idea that will embrace all trades, and yet have the balance of the advantages thrown the way of the photographer.

To simplify explanation, I will commence by enumerating a proposed set of rules, explaining or excusing them afterwards, and then proceeding to describe the interests of the various trades, and how their co-operation is to be used.

Proposed Rules.

1. The competition is open to any child between the ages of six months and seven years, who has been resident within the boundaries of this town (or borough) for a period not less than six months prior to the date of the opening of the competition.
2. Parents, relatives, or guardians wishing to enter a child must obtain an entry coupon from a tradesman who is officially authorised to distribute such coupon.
3. Having secured an entry coupon, the parent, relative, or guardian, must present it to the photographer whose name appears thereon, for the purpose of having the child's portrait taken.
   (Judging will be by photograph and public ballot.)
   The photographer will photograph the child in accordance with such instructions as have already been laid down by the organisers, and will charge a fee of 10s. 6d. in respect of the photographic work. The photograph shall be such as meets the approval of the child's parents, relative, or guardian, and shall have affixed to the back thereof the entry coupon and a photographer's certificate bearing the date when the photograph was taken, the name, age and full address of the child entrant.
4. The parent, relative, or guardian shall deliver the photograph to the Competition Committee at ———— not later than ————.
5. Judging will be by public ballot. The photographs being exhibited upon the screen at the ———— Cinema upon dates that will be announced in the local press.

In the event of a large number of entrants, lots will be drawn, and photographs exhibited in groups. The child obtaining the largest number of votes passing into the next round, and so on. The child obtaining the largest number of votes in the final round being adjudged the winner.

There will be three prizes: 1st prize, £400; 2nd prize, £200, 3rd prize, £100, and ten consolation prizes of £10 each. The tradesman who supplied the entry coupon to the 1st-prize winner will receive £25 and the photographer £25. The tradesman who supplied the entry coupon of the 2nd-prize winner will receive £10 and the photographer £10, and the

tradesman who supplied the entry coupon to the 3rd-prize winner will receive £5 and the photographer £5.

It will be seen that in order to make a scheme of this sort possible a prize fund of £880 is necessary. Organising expenses should be negligible. The organising could quite well be carried out gratuitously by a committee of photographers. In a town of 50,000 inhabitants it should be possible to raise such a sum as £880, while larger towns might do more.

The Photographer's Part.

In a town or borough of 50,000 inhabitants there will be probably somewhere about twenty photographers. Assuming an entry of 2,000, each photographer would obtain 100 clients at 10s. 6d. A keen business man would recognise that this is only the beginning, and additional copies, enlargements, etc., would no doubt be supplied in many cases.

The photographs should all be standard; *i.e.*, cabinet size, rough mounted, full length pictures, against white backgrounds. This would curtail in some degree the photographer's art, but allow of a fairer judgment of the sitters. Photographers might easily subscribe £3 each towards the prize fund.

Other Traders' Interest

All other traders in the town should be invited to subscribe £1. For this he would receive a definite number of entry coupons, to be given away (upon request) to any of his customers spending £1 or more upon his goods. The coupons should have a photographer's name printed upon them. Each photographer being allocated the same quantity. The larger stores could be invited to subscribe more than £1, receiving proportionately a larger quantity of coupons. The atmosphere to be created is that the trade is conferring a favour in supplying the coupon, or that the coupons cannot too easily be obtained.

A definite trial only will show how much money it would be possible to raise in this way, but from £700 to £800 should not be impossible.

The Cinema's Interest.

The assistance of the largest and best equipped cinema should be enlisted The entrants' pictures would be shown upon the screen each bearing a number. Patrons upon entering the hall would be provided with a small cardboard disc, or token, and asked to drop it in that ballot box bearing the number corresponding to the picture of the entrant they wish to favour. With a large number of entrants, and voting being extended over several weeks, a good deal of business would be attracted. The proprietors of the cinema, who would certainly be willing to bear the cost of lantern slides, may conceivably be persuaded to subscribe £100 to the prize fund in addition.

The Local Newspapers' Interest.

The local newspapers could without difficulty be induced to give all the publicity required. The cost of printing the entry coupons may also be considered, offering the newspaper the opportunity to advertise themselves thereon, if supplied without cost.

Such an undertaking properly organised, with keen business brains behind it, would stand a reasonable chance of obtaining the public interest and support. It would be of such a nature as to risk the least possible dissatisfaction upon the part of the unsuccessful public; it should stimulate trade generally; arouse a mutual interest between trade and clientele; would benefit all in some degree, and cost individually comparatively nothing.

The suggestions made are general ones. Individual towns may find it unworkable or unwarranted. Modification may be necessary, and there may arise numerous details that would require thought and careful handling.

Trade is bad, there is no use blinking the fact. The Government recognise that extraordinary methods are necessary in order to revive trade, and a Government financial department is now operating in the City (*i.e.*, The Trade Facilities Act Advisory Committee). When times are really bad it sometimes helps to fall back upon that primal instinct of mutual aid, and the proposals outlined in these notes are not so much a concrete plan to be followed, but rather a suggestion within which may be found a practical idea that may help to rejuvenate the photographic industry.

MERVYN THOMPSON.

A CONCENTRATED DEVELOPER FOR GENERAL USE.

[In the following article from "The Australasian Photo-Review," Mr. Edgar H. Booth, M.C., B.Sc., Lecturer in Physics in the University of Sydney, tells how to make up a concentrated developer for general use, and gives some notes on its employment.]

THE majority of photographers, both professional and amateur, who have progressed beyond the elementary stages have passed through the period when they required to have upon their shelves at least half-a-dozen different types of developer, or the means of making them. It is an interesting pastime, and very instructive—practice in manipulation is never time wasted. But we may use one standard developer which will give all desirable control—and it is better to be thoroughly familiar with the one solution rather than to have a slight knowledge of the peculiarities of many.

When we decide on one single developer for nearly all our work, we require it to fulfil certain conditions:—

(1) It must not stain the emulsion, nor the fingers.

(2) It must not cause chemical fog.

(3) We must be able to control it, so as to increase or decrease absolute contrast.

(4) It must be able to be manufactured and stored in highly concentrated form.

(5) It must keep well.

(6) The time spent in preparing working solutions from it must be short.

(7) It must be equally useful for plates, slides, gaslight, and bromide work.

(8) It must be composed of chemicals which are readily available, and not expensive.

This is not by any means an exhaustive list of requirements, but it sums up those that are of greatest interest to the ordinary worker. Other important requirements, so far as the scientific worker is concerned, are that one must be able to push development without causing blisters or frilling, and that it must be capable of being standardised.

A developer which satisfies the above conditions, and which I employ both in the laboratory for technical work, and outside for general photography is given below; the prescription has been passed on to a number of workers, who have found it to be quite satisfactory.

It is a one-solution M.Q. developer :—

	Metric System.	Apoth. System.
Metol	5.7 gms.	88 grs.
Hydroquinone ...	22.6 ,,	349 ,,
Water, distilled .	415 c.c.s.	14.6 fluid oz.

Heat the water to 50 deg. C. (112 deg. F.), and dissolve in it the metol and hydroquinone.

Add Soda sulphite

(anhydrous) ...	77.7 gms	1,199 grs.

Stir for two minutes. This will produce a greyish-white precipitate.

Add Caustic soda

(pure stick) ...	14.5 gms	224 grs.

Stir until all the soda is dissolved. The white precipitate will then have disappeared. Filter rapidly, and store for use.

If it is intended to make up developer to last for over three months, small bottles should be used to hold it. We make up our "Standard M.Q." into 8-oz. lots. But we have tested a 16-oz. bottle, using 4 ozs. per month, the bottles, of course, being kept stoppered when not in use. The developer grew gradually browner, but the oxidation was apparently so small a percentage of the possible amount that at the end of the four months a series of experiments showed the same times for stand and tank development to be satisfactory, and disclosed a total absence of staining.

Another point of interest in connection with this developer is that it contains no bromide—from a scientific viewpoint the presence of a bromide in a developing solution must have the effect of reducing the speed of the plate or film. In some tests which we made with this developer, using plates speed H. and D. 270 at time of exposure, on development they were found to function as plates of considerably lesser speed, according to the amount of potassium bromide added. (Down to speeds comparable with H. and D. 50.) This is, of course, an indication of procedure in cases of known over-exposure. Details as to the quantities of potassium bromide to be added are given later. Naturally, the addition of a bromide in the case of plate or film development is not recommended merely to enable fast plates to be used as slow plates—it does not alter the *size* of the silver grain. It is recommended simply as a means of correcting an error.

The Watkins factors for this developer are :—For soft pictures 13, normal 15, contrasty 18.

As with the majority of developers, the best temperature for working is from 60 deg. to 70 deg. F. We have used it at temperatures up to 90 deg. F., but naturally only under compulsion. As it is a developer with a caustic alkali, the rule should be to employ *always* a hardening bath if this will not interfere with subsequent work on the plate or paper—and if a hardening bath is not admissible, then not to develop at a temperature over 70 deg. F. The hardening bath employed is a saturated solution of potash alum, though the commercial acid fixing bath may be employed. Owing to a doubt as to the action of formaline on celluloid* the use of a formaline fixing bath is not recommended in the case of films.

The times for the following working strengths are for a temperature of 65 deg. F. :—

(1) *Plates or films.*—Standard M.Q. 1 part, distilled water 15 parts. Normal time of development, 4 minutes. For stand development.—Standard M.Q. 1 part, water 31 parts. Normal time of development, 8 minutes.

(2) *Bromide Papers.*—Standard M.Q. 1 part, water 15 parts.

(3) *Lantern Slides.*—Standard M.Q. 1 part, water 15 parts.

(4) *Gaslight Papers.*—Standard M.Q. 1 part, water 15 parts, to which add 1 drop of 10 per cent. solution potassium bromide per oz. of mixture for bromide effects, or 3 drops of 10 per cent. solution potassium bromide per oz. of mixture for black and white effects.

The test paper was Velox Glossy Regular. The times given for plates and films depend, of course, on the plate employed—it is best tested by the user himself with the material with which he normally works. If a slow tank development is desired, 15 minutes, in a solution 1 part Standard M.Q. to 63 parts water at 65 deg. F. will be found satisfactory. For extreme contrast in scientific work we push development until chemical fog begins, so as to get as great a density range as may be practicable. If we desire even greater contrast, as in the case of some line work, then we employ a strong bath of Farmer's hypo-ferricyanide reducer until the shadows are clear glass, without the high lights having been appreciably attacked. This is done prior to hardening. Probably 90 per cent. of our work may be done with the one developer—for after all the plate is only a means to an end, and M.Q. is fairly universally used for papers at present; so those photographers who do not care to go to the trouble of making up their own solutions are advised to keep to a single M.Q. developer, with which they may become familiar.

The only variations we make are the use of amidol, if we are to do much treatment of a particular plate and wish to avoid the use of the caustic alkali, and the employment of an M.Q.-Acetone developer where toned Velox prints are wanted direct.

For plates or films in cases of known over-exposure, add 5 drops of 10 per cent. solution potassium bromide as above per ounce of the solution Standard M.Q. 1 part, water 15 parts. If considerable over-exposure is feared, the amount of potassium bromide may be further increased. Develop fully, and reduce if necessary.

EDGAR H. BOOTH.

* A. Chargois, "B.J.," Dec. 19, 1919, p. 747.

THE PLASTOSCOPE.—Stereoscopic films have been a lode-star which has attracted cinema inventors for the past twenty years (writes the "Evening News" film expert). Several attempts and many near approaches to success have been made—notably the kineplastikon, which was shown at the Scala Theatre before the war—but they have not proved practicable. The Plastoscope, which was demonstrated last week, seems, however, to give a stereoscopic effect on the screen in a simple manner. It is an arrangement of prisms in a tubular attachment which is screwed on to the front of any projecting machine. The single picture projected by the machine is made into two by the prisms, and is sent out through two "eyepieces." Two distinct beams of light meet eventually on the screen and give to ordinary films a distinctly improved sense of "body" when seen on the flat screen.

PHOTOGRAPHING NOISES.—The lay Press last week published accounts of an instrument tested at Brooklands motor meeting by Dr. A. M. Low. The "noisemeter" (or audometer, to give it its technical name) was explained to some Press representatives by Dr. Low, who amused himself by photographing the bad coughs of some of his friends. "When you cough into the machine," he said, "it makes a photographic record. The sound impinges on a diaphragm connected with a very small mirror. When the diaphragm is oscillated by a sound wave the mirror rocks backwards and forwards. Then the spot of light is reflected from the mirror on to a sensitive film, which is moving automatically all the time, so that photographs of the noise-waves are taken as the air displacement occurs." Dr. Low (said the "Daily Chronicle" report) photographed at Brooklands the noises made by the cars as they took the strain of the steepest parts of the tracks. He has conducted some very fascinating experiments in London streets. "I have been photographing London noises for some time," he said, "and testing the effect upon the audometer." Omnibus companies have a special "noise" committee, and vehicles which have been repaired or constructed have to pass the committee's tests before being allowed to go out upon the London streets. The audometer is so sensitive that it detects and locates engine trouble.

PHOTOGRAPHIC METHODS OF TESTING DEVELOPERS.

[A communication from the Research Laboratory of the Eastman Kodak Company, reprinted from the "American Annual of Photography." The Elon mentioned, it may be stated, is metol (monomethyl paramidophenol sulphate) of Eastman manufacture.]

(*Continued from page* 156.)

Chemical Fog.

When comparing developers, we are only concerned with developer fog and not with fog inherent in the emulsion. Developer fog is caused by impurities or oxidation products of the developing agent formed during mixing. The importance of careful mixing of developers for test purposes is therefore apparent.

Interesting facts about fog are that the fog layer is not distributed evenly over the entire image, but is thinner in the high-lights because in those places where more image is developed, more potassium bromide is formed as a reaction product of development which therefore restrains the fog adjacent to the denser portions.

The absolute amount of fog depends on the volume of developer used. A film developed in a small volume of developer will have slightly less fog than if developed in a large volume, because in the former case the concentration of the bromide produced during development is greater.

Practical Determination of Fog.

Fog measurements are usually made by determining (*a*) the time required for fog to become just visible, and (*b*) the total fog density formed when development is complete.

(*a*) I. It has been found that a slow positive emulsion such as a lantern slide emulsion or motion picture positive emulsion, although very free from fog is very sensitive to the presence of impurities in the developer, and these emulsions are therefore very suitable for fog tests.

To make the test, first immerse one-half of the unexposed film in the developer and then, after one minute, completely immerse the film. Fog will therefore appear on the first half sooner than on the second half, and the time for the dividing line to become visible is taken as the fogging point.

(*b*) II. The total fog density is given by the density of the end or unexposed portion of the developed graded strip (Fig. 2). After the fog once appears its rate of growth is proportional to the time of development, that is, if the fog appears in two minutes and reaches a density of, say, 0.2 in four minutes, then the fog density in six minutes will be around 0.4.

The total fog formed after developing to an average contrast is usually proportional to the time of appearance of the fog, though as seen from the curve in fig. 5 it is possible that two developers in

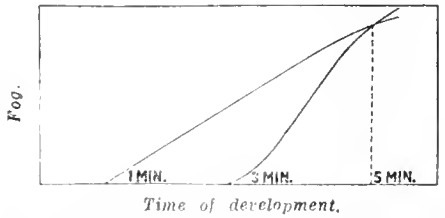

Fig 5 Curves showing the rate of growth of fog during development.

five minutes, say, might give the same fog but in three minutes the fog densities might be quite different. It is important, therefore, to consider both the time for fog and the total fog formed when development is complete.

Without a density measuring instrument the fog is most easily judged by laying the film, emulsion side down, on a sheet of white paper. With positive emulsions, such as lantern slides and motion picture positive film, no fog is permissible, but in the case of negatives, a very slight veil invariably forms by the time sufficient contrast is gained.

If a developer, which is otherwise satisfactory, gives excessive fog, the effect of the addition of a little potassium bromide should be tried before rejecting the developer. In the case of an energetic developer of the caustic-elon-hydroquinone type, bromide exerts a greater restraining action on the fog than on the image, so that increasing amounts of bromide should be tried up to, say, five grams per litre noticing carefully the effect on the lowest density and the density contrast of the graded test strip. If the fog is reduced to practical limits, and the density of the lowest step is not diminished to an extent equal to the original fog density, and if the density contrast is likewise not diminished, then the fog has been effectively eliminated.

Life of the Developer.

The active life of a developer is determined by

(*a*) The time required for the developer to oxidise by virtue of contact with the air, and, therefore, becomes useless either as a result of exhaustion or because of fog resulting from the oxidation products of the developer.

(*b*) The useful work which the developer will perform; that is, the number of films or prints developed when the solution is used continuously.

(*a*) The resistance of a developer to aerial oxidation is called the "keeping power" and is determined by measuring, say, 500 ccs. or 16 ozs. of developer into an open tray, allowing this to stand at room temperature, and making graded strip tests at frequent intervals, preferably daily. Before making the daily tests, the volume of developer should be brought up to the original five hundred ccs. with water, so as to compensate for loss by evaporation.

The keeping test should always be made in comparison with a standard known developer.

As the developer becomes oxidised, it usually turns dark brown in colour, though the rate at which a developer darkens in colour is no criterion of the rate of exhaustion, because some developers darken slightly the first day of exposure and do not darken further on keeping, though the developer might be totally exhausted on the third day. An unused MQ (Elon-hydroquinone) developer which on standing in a closed bottle turns slightly yellow and opalescent should be regarded with suspicion.

Keeping power is of great importance in the case of developers intended for use in tanks, such as in motion picture and amateur finishing work. It is of less importance for tray development.

If the developer refuses to develop after standing in an open tray for two or three days at 70 deg. F., it is useless for tank work. In the case of a developer with good keeping properties, the maximum density on the test graded strip will usually drop to about one-half in three or four days when applying the above test.

(*b*) The *useful* work test is made by exhausting the developer by developing a number of films or prints for a definite time in a definite volume of developer and noticing the time of appearance of the image and the point at which a change in colour or a weakening of the image occurs.

In practice, while the developer is being exhausted by virtue of developing the image, it is also being exhausted by aerial oxidation as a result of agitation, so that a strict exhaustion test could only be made by the impractical method of surrounding the developing tray or vessel with an atmosphere of an inert gas, say nitrogen, so as to prevent aerial oxidation.

The only final life test, therefore, is to exhaust the developer under actual working conditions.

If the developer oxidises rapidly an exhaustion test is not of much value, so that the keeping test should always be made first, and then an exhaustion test made if the developer appears promising.

Colour of Image.

The colour of the image is of most importance when developing paper prints and motion picture positive film. As a rule, Kodelon gives a greyish, hydroquinone a black, and amidol a blue-black image.

Tests for colour should always be made by cutting the test strips from a single sheet of film or paper, so as to insure that the tests are made on the same emulsion.

In the case of a negative, the colour is of less importance, because the quality of the negative is determined by the final print which it produces. The only coloured negative images met with in

practice are those given by pyro. Elon-hydroquinone images are termed "neutral deposits."

With pyro, the yellow stain, which is an oxidation product of pyro, may be distributed uniformly over the image, in which case the effect is the same as if a yellow filter had been placed over the negative, i.e., it increases the printing exposure. The stain may also consist of image stain, in which case each developed grain of silver is combined with more or less oxidation product stain, so that the pyro stained image is composite and consists of a neutral silver image and a yellow stain image, the latter image, therefore adding to the contrast.[4] It is for this reason that a yellow stained pyro negative gives a more contrasty print than an apparently similar negative developed in a non-staining developer. When comparing negatives developed with pyro, therefore, always compare prints made from the negatives and not the negatives alone.

For negative work, a developer is to be preferred which gives a fairly colourless deposit, because in the case of a pyro stained image the quantity of stain depends on so many factors, such as the time and temperature of the developer, the time of rinsing, the nature of the fixing bath, the time of washing, etc., that it is almost impossible to control the quality of the pyro stained negatives obtained. When judging two developers, one of which gives a neutral deposit and the other a pyro stained image, providing the two developers compare favourably as regards the capacity for rendering detail, fog, contrast, and keeping power, the developer which gives the neutral deposit or non-stained image is to be preferred.

Miscellaneous Factors for Comparison.

(*a*) *Effect of Dilution.* In many cases it is desirable to be able to dilute a developer so as to secure a certain contrast in a definite time, though, contrary to a popular notion, prolonged development with a weak developer does not always give better results than shorter development, say five minutes, in a stronger developer, and in many cases the results are inferior.

Pyro behaves normally on diluting up to three or four times; that is, the time of development is inversely proportional to the dilution, or if one volume of developer is diluted with, say, two volumes of water, in order to secure the same contrast the negatives should be developed for three times as long. The fog values for equal contrasts are likewise approximately equal.

A dilute developer, however, oxidises more rapidly than one which is more concentrated, the rate of oxidation being roughly proportional to the sulphite concentration. Sodium sulphite at strengths higher than 10 per cent. to 15 per cent. oxidises more or less slowly, but very rapidly at strengths below this. This is very apparent with developers intended for use with a reel and tank outfit. If the developer contains 10 per cent. to 15 per cent. of sodium sulphite, very little fog forms on churning up the developer, but if the developer is diluted with only 50 per cent. of water, fog may begin to form very rapidly.[5]

With Elon-hydroquinone the time of development is roughly inversely proportional to the dilution up to a dilution of one to three, though there is a tendency for the weak developer to give more fog than the stronger developer when developing to a given contrast. Beyond a certain dilution prolonged development does not increase contrast, because fog grows at a greater rate than the image.

A glycin developer will withstand more dilution than any other known developer and still behave rationally, and for this reason glycin has long been a favourite developer for tank work.

(*b*) *Effect of Temperature.* With developers such as hydroquinone development proceeds very slowly at low temperatures, so that a developer of this type, as compared with an Elon-hydroquinone developer tested under arctic conditions, would prove very unsatisfactory. For tropical work a developer is required which will not cause undue swelling of the gelatine or excessive fog.

(*c*) *Alkalinity.* A developer which is strongly alkaline shortens the life of the acid fixing bath, because the acid in the latter is rapidly neutralised by the alkali in the developer carried over by the films and prints, and under such conditions the films and prints are likely to become stained.[6]

Excessive alkali also tends to soften the gelatine film, so that, other factors being equal, a developer containing a minimum of alkali is to be preferred.

(*d*) *Cost.* The cost of the developer per unit of work performed is calculated by dividing the total cost of the developer (including labour) by the total area of the films and prints developed measured in square feet. A developer which is more expensive as regards chemicals, but which has a long life, is often cheaper in the long run, because the extra cost of chemicals is more than offset by the saving of labour and perhaps tie-up involved when mixing a new batch of developer.

(*e*) *Physical and Chemical Properties.* The solubility, colour, and crystalline form are of importance. A developing agent which is readily soluble in cold water and is white and crystalline is always to be preferred.

Developers of the monomethyl paraminophenol type are readily precipitated by a solution of sodium sulphite, which in many cases makes it impossible to prepare the developer in the highly concentrated form.

Practical Examples.

The following examples illustrate the methods of presenting reports on the various types of developers.[7]

1. Report on a Sample of Hydroquinone.

The sample was compared with a known pure sample of hydroquinone by first compounding the following MQ. formula with each sample:—

	Metric.	*Avoirdupois.*
Developing agent	5 gms.	75 grs.
Sodium sulphite (E.K. Co.)	75 gms.	2½ ozs.
Sodium carbonate (E.K. Co.)	25 gms.	375 grs.
Potassium bromide	1.5 gms.	20 grs.
Water to make	1 litre	32 ozs

Sheets of flashed motion picture positive film were developed in each developer side by side at 70 deg. F., and keeping tests made by exposing the developer for 24 hours in an open tray, taking care to dilute the developer to the original volume before testing each day in order to compensate for evaporation.

	Sample.	*Standard.*
Time of appearance	65 seconds	65 seconds
Time of appearance after 24 hours	165 seconds	160 seconds
Density in 6 minutes	1.94	2.00
Density after 24 hours	0.85	0.86
Time for fog at 70 deg. F.	11 minutes	12 minutes

The above results show that the sample consists of practically pure hydroquinone. Although the sample contains a trace of coloured impurity which produces a little fog, this would be negligible in practice.

2. Report on a Sample of Elon Substitute.

The sample was compared with pure samples of Elon and Kodelon (paraminophenol hydrochloride) by compounding the MQ. formula and testing on sheets of flashed motion picture positive film, as follows:—

Developing Agent.	*Time of Appearance.*	*Time for Fog at 70° F.*	*Density in 6 Minutes.*	*Fog.*
Elon	7 seconds	10 minutes	0.75	0.05
Sample	14 seconds	6 minutes	0.62	0.05
P. A. P. ..	30 seconds	16 minutes	0.49	0.03

From the above it is seen that the sample stands about half way between paraminophenol and Elon in its photographic behaviour. (Since the sample was so remote from Elon, it was unnecessary to make further tests.)

3. Report on the Developing Agent "X."

The developing agent "X" submitted consisted of light grey flakes, which were readily soluble in water and very readily precipitated by sodium sulphite. Preliminary experiments having shown that the developer behaved in a manner very similar to Elon, it was required to determine whether the developer became

4. See article on "Stains on Negatives and Prints," "Amer. Ann.," 1921, p. 204.
5. See article "Chemical Fog," "Amer. Ann.," 1919, p. 30.
6. See article on "Stains on Negatives and Prints," "Amer. Ann.," 1921, p. 204.
7. In the absence of a density measuring instrument the photographer can visually compare densities with sufficient accuracy by placing the two graded or flashed strips side by side, and examining the density of corresponding steps when looking through them against a uniformly illuminated light source such as a uniform sky. The lowest densities are best compared by laying down on a sheet of white paper.

exhausted at a greater rate than Elon. Developers were, therefore, compounded with equal weights of Elon and the sample "X," according to the MQ_0 formula, and sheets of flashed motion picture positive film developed in each developer for 7 minutes at 70 deg. F. The films were developed consecutively without loss of time so as to eliminate as far as possible errors due to oxidation of the developer, and the time of appearance noticed in each case. The results were as follows:—

	1st Sheet.		*10th Sheet.*		*20th Sheet.*	
	Time of Appearance.	*Density.*	*Time of Appearance.*	*Density.*	*Time of Appearance.*	*Density.*
Elon ..	5 seconds	2.5	12 seconds	1.5	40 seconds	0.98
Sample X ...	5 seconds	2.2	16 seconds	1.4	56 seconds	0.90

From the above tests it is seen that the sample X compares favourably with Elon as regards its photographic behaviour although the colour of the silver image produced was decidedly bluer than that given by Elon.

J. I. Crabtree.

(To be continued.)

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Panelling the Studio.

It is the desire of many a young photographer to do away with the stiff panel background which ties him everlastingly to just one part of his studio and a certain run of accessories, and to have his walls panelled so that he may use any part of his studio that he desires, and get the same effect from the genuine walls themselves.

But, alas! in these days of enormous bills for labour and materials—especially labour—few will employ the British—or any other—workman except upon compulsion, such, for instance, as for burst water pipes, and even then dread the receipt of the attendant bill.

However, there is a way out of it quite as effective as the "modern" antiques so largely used by photographers in the way of furnishings, and this method, which any photographer can make use of, requires only care, patience, and just the few tools I will now describe. It entirely depends for its success upon the care with which the work is done in the first instance, so that it may present a thoroughly workmanlike appearance.

Either the whole of the studio walls may be panelled, or a portion only of them, as is preferred, but in any case it is useful to include two sides of the wall, having a corner, and including also a door or window, or both.

The first proceeding is to select and cover the chosen walls with a perfectly plain dark brown paper. This work the photographer can quite easily carry out alone. Wall-paper is sold in rolls of standard size—22 inches wide and 12 yards long. To discover how much will be needed, measure the height from floor to ceiling, and also the length of the skirting board of the part to be papered, allowing for all recesses and window spaces. From these measurements the decorator will easily know how many rolls to supply.

Having bought the required amount of paper, a bucket of plain flour paste will be needed. Buy a 2-lb. bag of plain—on no account self-raising—flour. This will make nearly a gallon of paste. The flour is mixed to a thin cream, perfectly free from lumps, with cold water, and boiling water is poured into this, with constant stirring until the mixture "turns" and becomes semi-transparent and jelly like. If there should be any trouble to get it to "turn," the whole may be put on the fire and boiled until it "turns," but it will need constant stirring to keep it from getting lumpy. A table-spoonful of powdered alum or a few drops of almond oil may be added—especially if outside walls are to be papered—to prevent mould, mildew, and consequent "peeling" of the paper after it is on.

If the walls are already papered, and they are not to be stripped, the old paper should be first carefully rubbed down with a stale loaf, and any torn places, cracks, etc., first repaired with slips of thin paper, allowed to stretch well before being applied.

The secret of good paper-hanging is to apply the paste freely and evenly, and allow the paper to get quite limp and well stretched before it is put on the walls, so that it may dry tight, smooth, and free from creases, particularly as in the present case, where it is intended to imitate the effect of woodwork. A useful brush for applying the paste is the short-handled kind, about 18 inches wide, used by housemaids for cleaning stairs; a regular paper-hanger's paste-brush is a fairly expensive article, and is not at all necessary.

Open out the roll of paper, and cut it off roughly at the proper length for the height of the studio, allowing a fairly full measure, as it must be properly trimmed at the bottom after it is on. The length is then pasted. Be careful that you see which is the right and wrong side (plain papers are very deceptive), and hold the length up in a loop, back to back, as it receives its quota of paste. This looping up makes the long, sticky length much less awkward to handle. Always hang from the top downward, carefully rubbing down with a big, soft pad of cloth or a roller squeegee, so that there may not be a single crease or cockly patch to betray the paper foundation. Corners need care and the use of a ruler lengthwise to make them look neat and secure perfect contact. Previous experience in wet mounting will guide the photographer in such work as this, and prevent it from looking home-made.

When this portion of the work is completed, if a good warm-toned brown paper has been chosen, the walls should present almost the appearance of being of perfectly plain, grainless stained wood.

Next the panels must be formed by adding plain deal battens from floor to ceiling—or to within 9 inches of the ceiling—and long cross battens horizontally, thus completing the effect of longish narrow panels. The battens should be made of long strips of deal, from 2 to 4 inches wide. They may be bevelled off on two sides if desired, though this is quite unnecessary, and I prefer the plain effect myself. The height and width of the panels must, of course, depend on the height and width of the individual walls, and how they can be divided up to the best advantage, to give panels of even and uniform size all round, and to reduce the labour to a minimum.

Long lengths of wood of a narrow width can be ordered from any builder or timber merchant, of the kind used by builders for making door and window frames, and thus avoid sawing; it is also better wood, and of a uniform inch or inch-and-a-half thickness.

The proper number of uprights should be first sawn from the lengths, being very careful that they are a perfectly tight fit. Then cut off the cross pieces required. If the photographer has any mechanical skill he can with a tenon saw and chisel cut out a half-inch notch in each length of the strips where they cross each other, so that when fitted in place they will form a perfectly flush smooth joint, a small screw serving to make all secure. If, however, this calls for too much labour the cross pieces must be cut into short sections, and each nailed into its place crossways between the long battens.

The entire lengths must be well secured in place with nails—the oval wire nails are less likely to split the wood—and any bad joints filled in with a little putty well worked in and smoothed over.

Quite an artistic effect can be obtained by leaving the top 9 inches unpanelled, as a frieze, and fastening instead a plain narrow shelf along the top, say 6 inches wide, on which can be stood brass or china ware. To make this perfectly secure it is first nailed to the uprights, and then above is fitted very tightly a cross length of inch square wood, which, when well hammered down, will make the shelf quite secure.

If there is already a skirting board around the panelled portion this need not be disturbed, but will, of course, need staining along with the rest.

All the woodwork in the white now being in place, it only remains to stain it to the desired colour. If it is to be varnished, it is as well to give both paper and woodwork a preliminary priming of size and boiling water, applied with a good-sized brush while still hot. If it shows signs of getting streaky, it should be heated up again.

A good plan, however, is to first go all over the white woodwork with a solution of permanganate of potash which has been dissolved in cold water and allowed to stand uncovered overnight. The oxidation thus caused does away with the pinkish colour that permanganate gives when first mixed, and usually makes a stain that will be found a very good match for the wallpaper already

put on. The ready-made stains can be used instead if desired, but I find that they dry with almost too strong a gloss, which is apt to give disagreeable reflections when operating. Such a stain as Jackson's floor polish, however, if very largely diluted with turpentine substitute—this is quite good enough and much cheaper than turps at present—will also give a very good effect.

If for the sake of richness of appearance it is desired to varnish the paper, this should certainly have a first coat of size, and when this is thoroughly dry be given one quick coat of clear varnish This can be purchased in small quantities from any ironmongers', but it should be stated that the varnish is needed for wallpaper The effect of the size is to make the varnish go on quite smoothly and free from streakiness, and also to make it go further, as it does not dry into the paper so much as if used without the first priming.

If there is a margin of floor board showing between the wall and the edge of the carpet, it is as well to give this also a coat of the stain, so that the whole may harmonise, for dark walls and lighter floor boards look very ill-assorted.

Walls treated in this way photograph excellently, and with the advantage that sitter and camera can both be moved at discretion, and by the use of a little furniture of old-fashioned design exceedingly home like and effective studios can be obtained, well repaying the time and trouble expended by any photographer who does not feel justified in the expenditure that the erection of real panelling entails.—G. E. H. G.

Photo-Mechanical Notes.

Half-Tone Screens.

Particulars of a half-tone screen invented by Heinrich Illig, of 12, Michelstadt, Odenwald, Hessen, Germany, are given in a recent patent specification, No. 156,718, applied for under the International Convention in February, 1914, and granted in this country on February 16 last.

The screen consists of a glass plate *a* into the surface of which fields or recesses *c* are deepened by etching the recessed fields preferably having a square shape. They are filled up with any suitable substance of an opaque kind. The crossed lines *b* which border the fields *c* are transparent. The transparent lines may cross each other at any other angles than right angles, and in such case the fields *c* will have the shape of a parallelogram or rhombus.

If desired, the screen prepared as described may be strengthened by cementing or otherwise securing to it a backing or a front-plate of transparent material.

In carrying the invention into practice one or the other of the following methods may be employed

A net of crossing thin lines, destined to form the screen-netting, is transferred to the smooth surface of a transparent plate of glass.

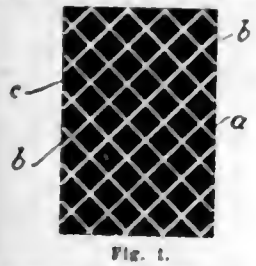

Fig. 1.

Fig. 2.

The screen netting transferred upon the glass consists of a suitable acid resisting paste, the print being preferably applied by an elastic printing plate or printing roller On spreading upon the plate of glass a suitable etching acid, the fields between the screen netting lines will be etched, while the lines protected by the print of paste, retain their original uniform height The deep etched fields or recesses then are filled up with a suitable opaque substance to an even uniform height flush with the transparent lines of the screen, and the printed lines are cleared of the paste by a suitable solvent, thus leaving a transparent netting of crossing transparent lines between opaque fields. The procedure may be the same as used in the offset printing process or in the line process.

According to another process a flat even plate of transparent glass is covered with a thin coating of wax, resinous matter, asphaltum or similar matter. Into this coating a net of crossing lines is traced laying the surface of the glass open where the lines have been drawn. The entire surface of the plate is then covered with a solution of silver or other plating metal of the kind employed in silvering or plating looking glasses, the solution adhering to the glass laid open in the lines of the screen while no deposit of the solution is formed upon the portions of glass covered by the coating of wax or the like. The coating is then removed by a suitable solvent, and the silvered or plated lines remain upon the glass. The squares or fields between the net of lines are deepened or sunk by etching the glass and the recesses thus obtained are filled up by an opaque substance. On removing the thin silver or metal coating from the lines of the screen, the lines are left transparent.

The following patents have been applied for :—

Lithographic Printing.—No. 6,237. Lithographic printing machinery. A. B. Evans

Lithographic Presses.—No. 6,241. Dampening mechanism for planographic or lithographic presses. Harris Automatic Press Co.

Lithographic Transfer.—No. 7,234. Preparation and treatment of photographic ferric films for lithographic transfer. H. L. Shawcross.

Exhibitions.

THE WELSH SALON OF PHOTOGRAPHY

was formally opened at the City Hall, Cardiff, last week, by Sir Thomas Mansel Franklin. Dr. W. Evan Hoyle, M.A., president of the Wales and Monmouthshire Federation, presided and described the exhibits, comprising landscapes, figure studies and portraits, as so excellent that it was difficult to distinguish the amateur from the professional section. Sir T. Mansel Franklin, Dr Hoyle mentioned, was himself a keen amateur photographer, and some of his works in book form were to be found in the Cardiff library In opening the exhibition, Sir Thomas traced the art of photography back to the days when Fox Talbot reproduced the first photograph. Photography, he said, was practised in Glamorgan as early as 1840 by Mr. Llewelyn, of Penllergaer, the speaker's uncle Alluding to the difficulty that the early photographer had to fight against, Sir Thomas said gradations of colour were unknown, a dead black and a dead white being the only colours at the photographer's command, and his capabilities were therefore sadly limited The discovery of isochromatic plates, however, proved the solution of this difficulty, and photography became firmly established

Mr. Henry Storm, chairman of the Federation Council, remarked with pride that one-tenth of the exhibits in the London Salon of Photography were contributed by Cardiff men.

Certificates were awarded to works by the following :—Open class, Hugo Van Wadenoyen, jun., H. Storm, W. Gilbert Scott, and J. A. Lomax (all of Cardiff). Federation class: Gwyn Morgan and T. J. Lewis (Barry), G. T. Frisk (Cardiff), and Aubrey Raymond (Neath), Beginners' section: Miss L. Wickett and A. Dure (Barry), and George W. Robinson (Porth).

FORTHCOMING EXHIBITIONS

March 4 to 25. South London Photographic Society. Particulars from the Hon. Secretary, Harry Abbott, 61, Beauval Road, East Dulwich, London, S.E.22.

March 27 to April 8. Dennistoun Amateur Photographic Association. Particulars from the Exhibition Secretary, Colin Graham, 448 Duke Street, Dennistoun, Glasgow.

March 28 to April 1. Hackney Photographic Society. Hon. Secretary, Walter Selfe, 23, Pembury Road, Clapton, London, E.5.

April 5 to 8. Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester

April 5 to 8.—Faversham Institute Photographic Society. Latest date for entries, March 31. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Latest date for entries, March 30. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications are treated in "Photo-Mechanical Notes."

Applications March 6 to 11 :—

REFLEX CAMERAS.—No. 6,676 Photographic reflex cameras. W. C. Adams and J. P. Glover.

CAMERA MOUNTINGS.—No. 6,494. Mountings for photographic cameras. G. W. Cooper and Stereo Kinema Syndicate, Ltd.

FRAMES.—No. 6,615. Photo or picture frames. Deakin & Francis, Ltd., and F. Shuttleworth.

COLOUR PHOTOGRAPHY.—No. 6,722. Colour photography. A. Hamburger.

COLOUR CINEMATOGRAPHY.—No. 7,096 Natural-colour cinematograph, etc., films and plates. J. C. Lyell.

CINEMATOGRAPHY.—Nos. 7,206 and 7,217. Cinematographic apparatus. G. S. James.

CINEMATOGRAPHY.—No. 7,033. Cinematograph apparatus. E. J Way.

CINEMATOGRAPHY.—No. 7,034. Apparatus for manipulating cinematograph film. E. J. Way.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

MULTIPLE IMAGES WITH ONE LENS.—No. 173,571 (September 6, 1920). In the known optical system shown in figs. 1 and 2, the rays of light passing through the camera lens 1 are split up by the semi-transparent reflector 2 arranged in the path of these rays. The reflector 2 is a mirror having bars 3 of reflecting surface alternating with transparent spaces 4. The strips 3 will reflect a portion of the light-rays transmitted through the lens 1 on to the reflector 5, which in turn reflects the light-rays on to the sensitive surface 6. The light-rays passing through the transparent strips 4 of reflector 2 are reflected by the inclined reflecting-surface 7 on to a similar reflector 8 and thence to the plate or film 6. The reflectors 5 and 8 are arranged on opposite sides of the axis of the lens 1 so as to produce two images upon the plate 6.

Fig. 3 shows the adjusting means for the reflectors arranged according to the invention. The various parts of the apparatus are mounted upon the inner face of the lens board 9, of a suitable camera. This lens board 9 carries the usual lens 10 with shutter 11 and behind the lens 10 is mounted the semi-transparent reflector 2 supported in a suitable frame 12 and secured by a bracket 13 to the inner face of the lens board 9. Beneath the

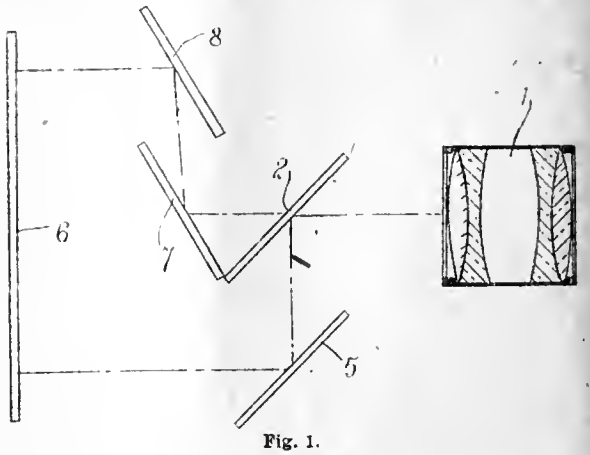

Fig. 1.

semi-transparent reflector 2 is arranged the reflector 5 mounted in a frame 14. This frame 14 is pivotally supported in arms 15 secured by their bent ends 16 to the inner surface of the lens board 9. The frame 14 carrying the reflector 5 may swing about its pivotal connection to the arms 15 so that its angle may be

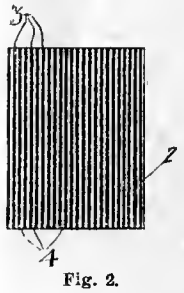

Fig. 2.

adjusted so as to receive the rays of light reflected from the semi-transparent mirror 2, and to reflect them again on to the sensitive film.

Behind the transparent reflector 2 is mounted the inclined

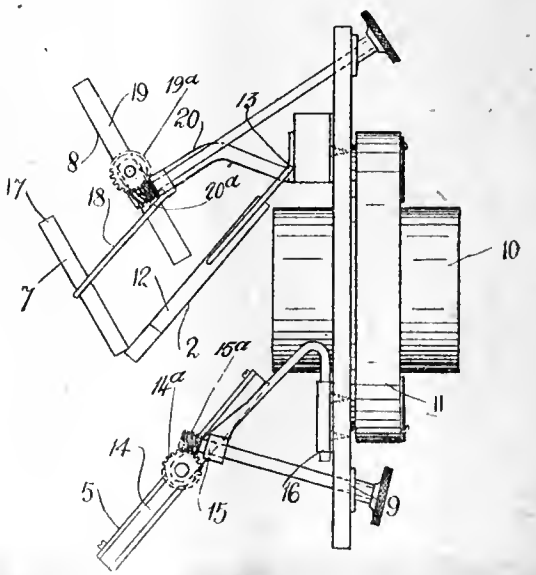

Fig. 3.

mirror 7 in a suitable frame 17. This frame 17 is supported on brackets 18 which are carried by the brackets 20 supporting the frame 19 of the reflector 8, which is arranged substantially parallel to the reflector 7. The brackets 20 are mounted upon

the inner face of the lens board 9. The position of the mirrors is such that the distance from the optical centre of the lens 10 to the reflecting surface of the transparent mirror 2, thence to the mirror 5 and on to the sensitive surface of the plate or film is equal to the distance from the optical centre of the lens to the surface of the mirror 7, thence to the mirror 8, and on to the surface of the sensitive film or plate. In this manner the distance over which the rays of light have to pass from the lens to the surface of the films or plate will be the same for both images formed, so that they will be substantially identical images and of a similar size. By turning the frame 14 in which the mirror 5 is mounted about its pivotal connection with the supporting arms 15, the angle of the mirror may be altered so as to move the position of the image reflected from this mirror. The frames 14 and 19 in which the reflectors or mirrors 5 and 8 respectively are mounted may be carried by spindles, at least one end of each of which is extended, and each of these extensions of the spindles carries a worm wheel 14^a and 19^a engaged by worms 15^a and 20^a, so that the relative angles of the reflectors with relation to the light-rays passing through the lens may be varied. The device may be applied to cinematograph cameras, in which case it is preferred to produce the two images upon the one film so that the images lie on top of each other but slightly out of register so as to produce a stereoscopic effect when projected. The pictures may also be arranged in pairs of separate pictures arranged one above the other so that upon being exhibited simultaneously through ordinary projectors a relief or stereoscopic effect will be obtained if the pictures are produced on the screen slightly out of register.—Reginald Killick and Hester Stewart, 152, Fulham Palace Road, London, W.6.

The following complete specifications are open to public inspection before acceptance :—

Reversal Processes.—No. 176,357. Photographic reversal processes. Kodak, Ltd.

Relief Cinematography.—No. 176,369 Cinematograph screens adapted to give to an observer the impression of pictures in relief. A. V. F. Marion.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Carbine (Stork Design).—No. 421,863. Sensitised films for use in photography. William Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, manufacturers. December 28, 1921.

Kosmos.—No. 417,223. Photographic plates and films, and chemical substances prepared for use in photography. Kosmos Photographics, Ltd., Balfour House, Finsbury Pavement, London, E.C.2; manufacturers of photographic papers, plates and apparatus. July 25, 1921.

Velox (Design).—No. 421,046. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials. November 30, 1921.

Velox (Two Designs).—No. 421,423. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials. December 12, 1921.

Velox (Four Designs).—No. 421,045. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2. November 30, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

Kristal.—No. 416,794. Photographic dry plates. The Leto Photographic Materials Co. (1905), Ltd., 1, Crutched Friars, London, E.C.3; photographic manufacturers.

Planior.—No. 403,377. Lenses. Francisque Falsex, Route de Houdan, Auffreville par Mantes, Seine et Oise, France, manufacturer.

Lumex.—No. 404,988. Photographic cameras. Lumex, Ltd., 31, Dame Street, Dublin, Ireland, manufacturers of and dealers in photographic, optical and scientific apparatus.

Fairitype.—No. 407,027. Photographic enlargements. Adelphi Studios, Ltd., 60, Strand, London, W.C.2, photographers.

Retanol.—No. 408,222. Photographic chemicals. Johnson & Sons, Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, E.C.2, manufacturing chemists.

Petra.—No. 405,701. Photographic chemicals, plates and films. Petra Aktiengesellschaft für Elektromechanik, 18-20, Niederwallstrasse, Berlin C., Germany, manufacturers.

Carbro (Design).—No. 405,226. Chemical substances for use in photography. Walter Montague Rouse, trading as The Autotype Company, 74, New Oxford Street, London, W.C.1, manufacturer.

Sundora (Design).—No. 408,026. Photograph albums. Arthur Gill, 46, Sixth Avenue, Manor Park, Essex, company director.

Negopock.—No. 408,817. A folding photographic camera. The Russian Company for Foreign Trade, Ltd., 57, Shoe Lane, London, E.C.4, merchants.

Chat-tone Series (Design).—No. 409,389. Pictorial postcards, photographs and drawings. Frederick James Saxton Chatterton, 34, Elm Park Road, Finchley, London, N.3, artist and journalist.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, March 21, Mr. T. H. B. Scott in the chair.

The chairman announced that Mr. F. F. Renwick had resigned his office as vice president of the Society, consequent upon his leaving shortly to take up a position in the United States with the Du Pont de Nemours Company, of Parlin, N.J. The Council had elected Mr. T. H. B. Scott to take his place, and had further nominated Mr. Herbert Lambert as a member of the Council.

Mr. S. Bridgen then delivered a long lecture on "Landscape from the Practical Side." He dealt very fully with the equipment, materials and methods which he adopted in his own pictorial work, had some hints to give on composition in landscape photography, and, in fact, contributed a host of information on the practical side of pictorial landscape work.

A most hearty vote of thanks was accorded to Mr. Bridgen.

CROYDON CAMERA CLUB.

Mr. W. Sanderson, J.P., gave an exceedingly interesting lantern lecture on "Southern Italy," a subject, as the President poetically observed, particularly appropriate to the approach of spring, "When birds burst open and buds twitter merrily."

Mr. Sanderson rarely jumps abruptly from one important place to another, but in pleasantly conducted-tour fashion shows his audience intervening scenery, which establishes a nice feeling of continuity and rest. Perhaps the most interesting part of the lecture consisted of photographs of Messina taken before and after the last terrible earthquake in 1908, when many thousands lost their lives in a few seconds.

Technically, the only point of interest which arose related to exposure. In a good light in Italy he almost invariably uses one shutter speed of 1/100th second (presumably so marked), with a lens working at $f/6.5$, on fast, but not ultra-rapid, plates. Open views and narrow street scenes receive the same exposure measured in duration of time, and although the general quality of the slides was very good, some of the negatives certainly had not been surfeited with light-action.

This simple system sadly upset Mr. Harpur, who, in portly, portentous fashion, and, more in sorrow than in anger, admonished the lecturer. But subtlely he conveyed the idea that the amenities necessarily extended to an ever welcome visitor alone prevented his reduction to a small heap of ashes. Mr. Jobling found himself in agreement with Mr. Harpur, and imparted much information on exposure. Sad to relate, Mr. Sanderson remained unconverted and unrepentant. A most hearty vote of thanks was accorded him.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Annual General Meeting.

The annual general meeting of the Association was held at 35, Russell Square, W.C., on Friday, March 10, 1922, at 6.30. Mr. Swan Watson (President) was in the chair, and there was a numerous attendance.

The minutes of the last annual general meeting and of the special general meeting having been confirmed,

The President referred to the death of the late Secretary, Mr. S. H. Fry. All who came into contact with him, he said, must have been greatly impressed with the wholeheartedness with which he did his work. His interest in the Association and in the profession was great and unselfish. As far back as the speaker could remember in photography Mr. Fry's name had been held in the highest respect. He thought the meeting would desire that this small tribute be put on record. (Hear, hear.)

The annual report of the Council was taken as read.

Mr. R. N. Speaight presented the annual balance-sheet. He thought that the Society's financial position was very satisfactory, particularly in view of the present depression. It was not quite so good a report as last year, but this was explained by the special circumstances under which the last Congress was held. It was held in the midst of great industrial upheaval, when most people thought them plucky in holding a congress at all, and considering that the loss on the Congress was only £17 the issue was very creditable to the Association. In the previous year the profit was something like £40, and this reversal from profit to loss on the Congress accounted for nearly all the difference—between £60 and £70—by which they were below the last year's record. There was a balance, being excess of income over expenditure, of £65, and another £100 had been added to the reserve.

Mr. A. Barratt asked a number of questions bearing on the accounts.

Mr. Speaight replied that the accounts were made up to December 31 last, on which date the old Association was in being. The expenditure on the "Circular" represented one issue. A new journal was being proposed, and would be issued shortly on a larger scale. It had been thought unwise to tax the accounts for one year only with the legal charges incurred in incorporation, and, therefore, while a sum of five guineas appeared in the statement of expenditure a similar sum in suspense was given among the assets, so that the expenses attending incorporation, which scarcely belonged to last year at all, might be more fairly distributed. The present price of the Association's investments was something like £15 above the cost price at which they were shown in the balance-sheet.

Mr. Barratt then moved the adoption of the report of Council and balance-sheet, and this was seconded by Mr. Chaplin Jones, and carried unanimously.

The President, in putting the motion, referred to the hours of labour which had been expended by Mr. Speaight as treasurer upon the finances of the Association.

Mr. A. Ellis (Chairman of Council) said that he wished to make it clear that this annual general meeting was a meeting of the old Association, not a meeting of the limited liability company. There were certain formalities which had still to be gone through, and until they were completed it could not be said that they were a fully fledged company. At that meeting they should be electing a President and Council, but under the provisions of the new Association it was arranged (Article 39, which he read), that they go forward into the new Association with the same President and Council as they had now. In addition to this statement he had to propose a resolution which had been drafted by the Solicitor as follows:—

"It appearing that the registration of the intended new Association has become effective, and that all the assets of the Association have been transferred to the new Association, and books handed over to the new Association, and there being no further usefulness in the continued existence of the Association, it is hereby resolved that the said Association be and at the same time is hereby dissolved."

He had much pleasure in moving that resolution.

Mr. F. H. Read seconded, and the resolution was carried unanimously.

Mr. Ellis then said that in order to have the general meeting at the Congress it was necessary that the present meeting be adjourned until the Congress in September, instead of being formally closed in the ordinary way. He moved, therefore, that the meeting be adjourned.

Mr. W. Illingworth seconded, and this was carried unanimously.

General discussion was then invited.

Mr. F. G. Wakefield asked what happened to those members who had not paid their liabilities to the old Association. Were those liabilities wiped out when the Association became the new body? He asked for the Solicitor's opinion.

Mr. Speaight (in the absence of the Solicitor) said that he could give the Treasurer's opinion, which was that they were still owing, and would be collected by all means.

The President suggested that at the Congress time might be spared for the discussion of some professional matters, such, for example, as the desirability or otherwise of putting into print the prices they might charge for commercial work. Many questions of the kind might be talked over informally at the Congress to their great mutual advantage, and he hoped that members would bring forward such matters for discussion.

Mr. Marcus Adams proposed that the best thanks of the meeting be given to Mr. Swan Watson for presiding. He said that Mr. Swan Watson had travelled from Edinburgh all the previous night, and was about to journey back that same evening, this representing no small sacrifice in the Association's interests. (Applause.)

Mr. T. C. Turner seconded the resolution, and said how much they had all enjoyed the able and delightful way in which the

President conducted their business. There was an instinct of happiness in him which was really contagious, and which affected the whole meeting.

Mr. Frank Brown, as a Past-President, cordially supported the vote. He had thought on many occasions that a man of their President's age——

The President: Only thirty-two. (Laughter.)

Mr. Brown accepted the correction, and went on to say that, however youthful he might be, the President was to be highly commended for his very regular attendance at the Council meetings.

The vote of thanks was carried by acclamation.

The President, in responding, recalled that he had a good Scotch aunt who used to pray, audibly, that the boy would be kept from getting conceited. He was afraid that that evening if she heard what was said she might fear that her prayers had been unanswered. Certainly it was an expensive business for a Scotsman to visit London. Bang went a good many saxpences! But it was a great pleasure to him to do anything for the profession he loved. If he had his time to come over again he would still be a photographer.

Mr. Lang Sims said that as this was the last meeting of the old Association, an occasion which brought a feeling of regret to many of them who had been members of the Association for many years, he thought that a vote of thanks should be given to the Council. He could propose this because, as Secretary, he was not a member of the Executive. Many of the members of Council attended at great personal sacrifice. It cost the President £10 every time he came. Yet there were members who would fling stones at the Council. Such members were unaware of the services which the Council put in on behalf of the Association. Their Chairman (Mr. Ellis), one of the oldest members of the Association, never missed a meeting. The London members of Council had special calls upon them, and often there were committee meetings, for which Mr. Speaight kindly lent his studios. He moved that a vote of thanks be accorded to the Council.

Mr. Frank Brown seconded, and the motion was carried unanimously.

Mr. Barratt asked for some announcement with regard to the Congress.

Mr. Lang Sims said that although matters were not ripe enough for definite announcements, he could assure the members that there would be some surprises. The Council was making a great effort to ensure a highly successful Congress. Another matter which the Council had decided only that afternoon was to bring out a journal, which would be a great advance upon anything in the past. The propaganda work of the Association was going forward very energetically. The preparations for the Congress were distributed among several committees, each with its appointed task, and the Congress would be something they would be proud of.

The President read a letter from the Photographers' Association of America extending to the Association in Great Britain a corresponding membership, which in effect would be that any member in good standing in the Professional Photographers' Association would upon presentation of his membership card be admitted on the same status to the members of the American Association, but without vote, and exempt from fee or dues, to any international convention of photographers in America. The next Convention of the kind was to be held in Kansas City from May 1 to 6, inclusive, and it was desired to have a representative exhibit of British work to show at this Convention.

Mr. Marcus Adams said that the collection of a suitable exhibit for this Convention had been entrusted to him, and he asked that members should send specimens of their work to him in sizes exceeding 12 x 10. He also mentioned that Mr. Pirie Macdonald was collecting one of the finest collections of portraiture to send to their own exhibition.

Mr. Reginald Haines said that Mr. Pirie Macdonald intended to come to their Congress and give them a lecture, also some other distinguished photographers from the States, including Mr. Abel, the Secretary of the American Association, a "live wire" if ever there was one. As for the American Convention, if any member could visit it, he would guarantee that he would get a reception that would live in his memory for the rest of his life.

This concluded the business of the annual general meeting, which stood adjourned. Mr. T. C. Turner then gave a short address and demonstration on up-to-date methods of electric lighting in the studio, a report of which is held over to appear in the next issue of "B.J."

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Margaret Pickles and Julie Louden, carrying on business as photographers at 27, Central-drive, Blackpool, under the style of Louden and Pickles. All debts due to and owing by the late firm will be paid to or by Julie Louden.

NEW COMPANIES.

MACPHAIL, ADVERTISING SERVICE, LTD.—This private company was registered in Edinburgh on March 9 with a capital of £2,000 in 1,800 cumulative preference shares of £1 each and 4,000 ordinary of 1s. each. Objects: To carry on the business of advertising agents, stationers, lithographers, stereotypers, photographic and general printers, engravers, die sinkers, etc. The first directors are: W. A. Macphail, 91, Hyndland Street, Glasgow, advertising agent, and J. Barrowman, 248, Kenmure Street, Glasgow, advertising agent. Qualification: £10 in shares. Registered office: 29, Waterloo Street, Glasgow.

VEGA, LTD.—This private company was registered on March 8 with a capital of £600 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in preparations for apparatus, plant, chemicals, and preparations for technical, commercial, photographic, manufacturing, engineering, scientific purposes, etc. The permanent and governing directors are: A. V. Elsden, 15, Coleraine Road, Westcombe Park, Blackheath, S.E.3, civil servant, and D. D. Jones, 17, Edmund Road, Hastings, officer in the Merchant Service. Secretary: E. E. D. Jones. Registered office: 518, Woolwich Road, Charlton, S.E.7.

ANDERSON, LTD.—Private company. Registered in Edinburgh, February 28. Capital, £300 in £1 shares. To carry on the business of photographers, photographic artists, print-sellers, fine art publishers, etc. The subscribers (each with one share) are: Carl Heinrich Theodor Schmidt, 34, Comely Bank Avenue, Edinburgh, photographer; Charles Smith, 34, Comely Bank Avenue, Edinburgh, photographer; Alexander Easton Hamilton, 34, Comely Bank Avenue, Edinburgh, jewellers' assistant. The first directors are C. Smith and A. E. Hamilton. Secretary: A. G. Bryson. Registered office: 58, Queen Street, Edinburgh.

H. LUSCOMBE TOMS & CO., LTD.—This private company was registered on March 8, with a capital of £3,200 in £1 shares (2,000 preferred ordinary and 1,200 ordinary). Objects: To adopt an agreement with H. Luscombe Toms and E. Bastard, and to carry on the business of photographic publishers, optical lantern slide makers, cinematograph film producers, scenic artists and painters, entertainment contractors, press photographers, manufacturers of and dealers in wet or dry plates, papers, films and transparencies, photographic materials, etc. The permanent directors are: H. Luscombe Toms, 52, Queen Victoria Street, E.C., lantern slide manufacturer (managing director); E. Bastard, 1, Dersingham Villas, Strathearn Road, Sutton, Surrey, photographer (assistant manager). Registered office: 52, Queen Victoria Street, E.C.

KEYSTONE VIEW CO. Particulars of the Keystone View Co. (Incorporated) were filed on March 7, pursuant to Section 274 of the Companies (Consolidation) Act. The company was incorporated in New York on January 6, 1920, to manufacture and deal in photographs, art prints, paintings, etchings, objects of art and artcraft, and all supplies in connection with the photographic business; and photography and pictorial service to newspapers. The capital is $130,000 in $100 shares. The British address is 1, Wine Office Court, Fleet Street, E.C., where B. Garai is authorised to accept service of process and notices on behalf of the company. The directors are: H. W. Sierichs and Emma P. Willey, of 91, Seventh Avenue, New York, and B. L. Singley, S. L. Hart, and F. M. Walrath, all of Meadville, Pa., U.S.A. The file number is 2,087F.

KINATICOL SYNDICATE, LTD.—This company was registered on March 13 with a capital of £25,000 in 20,000 10 per cent. cumulative participating preference shares of £1 each and 20,000 ordinary shares of 5s. each. Objects: To carry on experiments in natural colour and other photography, and the improvement of

processes connected therewith, and the business of producers and distributors of cinematograph films, etc. The first directors are: G. St. Lawrence Mowbray, Isfryn, Kew, Surrey, banker, and R. J. Watson, 8, Stonor Road, West Kensington, W., banker. Minimum cash subscription: Seven £1 shares. Qualification, after ordinary general meeting in 1923: £500. Remuneration: £100 each per annum (chairman £150) and a percentage of the profits. Secretary: A. Williams. Registered office: 57, Palace Street, Westminster, S.W.1.

Mayflower Syndicate, Ltd.—The Mayflower Syndicate, Ltd., has been registered as a "private" company with a nominal capital of £100 in 1s. shares. The objects are: To adopt an agreement between F. W. May of the one part, and Lieut.-Col. Sir Edward Bellingham, Bart. (H.M.L. for County Louth), C.M.G., D.S.O., and F. Bolton (on behalf of this company) of the other part, and to carry on in the United Kingdom or elsewhere (either directly or through the agency of any other company in which this company holds shares) the business of manufacturers, hirers, sensitisers, treaters, finishers, colourers, toners, letters on hire, renters, importers, and exporters or exchangers of all bases whatever, whether sensitised, partly sensitised or otherwise, on which photographs, pictures, outlines, designs, diagrams, etc., may be photographed, produced or reproduced, whether in colour or otherwise; manufacturers of and dealers in cinematograph projectors, cameras and apparatus, films, cinematographs, phonographs and sound-producing machines, musical instruments, etc. Permanent governing directors: Fredk. W. May (technical manager), Sheeps Head Bay, Long Island, U.S.A. (at present resident at 11, Passauerstrasse, Berlin, Germany); Lt.-Col. Sir Edwd. Bellingham, Bart., H.M.L. for County Louth, C.M.G., D.S.O. (chairman), Castle Bellingham, Ireland; F. Bolton (managing director), Anglo House, Litchfield Street, W.C. (managing director Anglo Film Agencies, Ltd.); R. A. Leckie, 23, Lime Street, E.C.; Elfreda M. Fries, 11, Passauerstrasse, Berlin, Germany; Capt. Chas. M. King, Guards Club, Brook Street, W. Qualification, 10 shares. Remuneration of governing directors (chairman £100 extra) shall be equal, and shall not be less than £200 over, above and in addition to that payable to each ordinary director. The registered office is at 1, Litchfield Street, W.C. File No. 180,077.

News and Notes.

Glass Works in Germany, says a Reuter correspondent, have decided to raise the price of glass made for dry plates by 15 per cent.

A Photographic Lady as J.P.—Mrs. M. W. Acworth, wife of Dr. J. J. Acworth, Ph.D., the photographic chemist and inventor and founder of the Imperial Dry-Plate Co., has been appointed as Willesden's first woman J.P. Mrs. Acworth (Marion Stevenson), who married in 1893, was also the first lady A.R.C.Sc.

Royal Institution.—On Thursday (March 30) Professor A. M. Hind delivers the first of two lectures on "Landscape Etchers: New and Old." The Friday evening discourse on March 31 will be delivered by Mr. A. B. Walkley on "Jane Austen"; and on April 7, by Sir Ernest Rutherford on the "Evolution of the Elements."

Royal Photographic Society.—At the meeting arranged by the Scientific and Technical Group, for Tuesday next, March 28, a paper on the Trist three-colour exposure camera will be read by Mr. A. C. Banfield. Two papers dealing with the "Osglim" lamp and its uses for photographic purposes will also be read by representatives of the General Electric Co. and Messrs. Ilford, Ltd.

Summer Time Dates.—An Order has been made in Council directing that summer time shall come into force this year at 2 o'clock, Greenwich mean time, on the morning of Sunday next, March 26, and shall continue until 2 o'clock, Greenwich mean time, on the morning of Sunday, October 8. This period has been fixed in accordance with the agreement made recently with France and Belgium to secure uniformity between the three countries.

Photography at the Zoo.—Dr. Chalmers Mitchell, secretary of the Zoological Society, lecturing at the Royal Institution last week, stated that many animals of which there were no photographic records were now quite extinct, and they wanted cinema records of every rare animal and every common animal, so that they might have them preserved for the future. At the Zoo they had an expert photographer, who took film records of all animals that came into their possession.

Size of German Picture Postcards.—According to a German correspondent on the staff of one of the London dailies you have to be very careful about the size of picture postcards in the Fatherland. You must measure your card very carefully, for some of the ex-King of Saxony's postcards, conveying birthday wishes to friends, were recently returned to the distinguished sender with the remark by a wide-awake Post Office official: "Too large to go at postcard rates." The ex-King's private secretary discovered, with the aid of the big book of Post Office Regulations, that they were one-thirtieth of an inch too broad!

Photographic Goods per Foreign Parcels Post.—Manufacturers of photographic materials and business men generally who have long been complaining that the maximum weight for parcels abroad—11 lb., and in some cases less—is not sufficient, have been wondering what are the "serious practical difficulties" mentioned in a recent Parliamentary answer. The G.P.O. authorities now state that the greatest obstacle to increase of weight is the fact that all parcels before they become "foreign" are "inland," whose weight must not exceed 11 lb. Before any change could be made, contracts with railway companies, fittings in sorting offices, the size of mail bags, and other factors have to be considered.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE FOX TALBOT MEMORIAL.

To the Editors.

Gentlemen,—I have recently received a letter from Miss M. Talbot, to whom we are indebted for the apparatus used by her grandfather and now included in our museum, where it is available for inspection, expressing the wish that the Fund collected should be, if possible, devoted to the endowment of an annual lecture *on photographic developments or on any kindred subject which might be helpful to practical photographers, whether professional or amateur.* (I underline the exact wording of her communication.) The Council of the Royal Photographic Society recently appointed the new President, Mr. W. L. F. Wastell, the Hon. Treasurer, Mr. E. W. Mellor, and myself to act as Trustees of the Fund, and in due course a scheme will be formulated for adoption later on, on the lines suggested by Miss Talbot.

May I add that the amount subscribed is gradually increasing, and that Mr. W. L. F. Wastell and Mr. G. C. Weston will be pleased to receive any further contributions sent to them at 35, Russell Square?—I am, yours faithfully,

Geo. H. Rodman.

March 18

MEASURING FOCAL LENGTH OF LENS.

To the Editors.

Gentlemen,—I have been interested in the paper by Messrs. Jobling and Salt on the Clay method of finding the focus of a lens. Unfortunately, however accurate the result may be, an appliance is required that is not in the possession of most photographers, and it would be interesting if the gentlemen named will apply themselves to the measurement of the foci of the lenses in most general use—the Petzval portrait lens, the aplanat of Steinheil, generally sold as rapid rectilinear and rapid symmetrical, an anastigmat

doublet, and the Cooke lens (the Aldis lens, having a special construction, might also be included)—and will take the measures also by the method in general use, and let us know the difference, so that the photographer may judge whether the amount is of importance. I have not now the conveniences for making these experiments myself.

The usual method, I suppose, is that which I published in the "British Journal of Photography," September 19, 1879, and was reprinted in the "B.J. Almanac" for many years in a useful page of optical calculations by Mr. Branfill. A concrete example of it was also adopted (this time without acknowledgment) by another writer. As these old papers may not be within the reach of many photographers, it may be well to re-state the rule. Focus the image of some object, say, a foot rule or a sheet of card with two crosses a foot apart marked upon it, to some definite scale. Suppose the foot is rendered as three inches upon the ground glass, the scale will be four to one. Measure the distance from the object to the image, multiply by the figure representing the scale, and divide the product by the square of a number, one higher than that by which it has been multiplied. Thus, supposing the distance from the original to the ground glass to be 50 inches and the scale four to one, $\frac{50 \times 4}{25} = 8$, and the lens has a principal focus of 8 inches.

—Yours, etc., W. E. Debenham.
Hampstead, March 13.

THE PERMANGANATE REDUCER.

To the Editors.

Gentlemen,—I was interested in reading your note in the "B.J." of March 3 regarding the small use made of the permanganate reducer. I have for years employed it in lantern slide work (also for negatives), and for reducing an over-dense slide consider it unequalled. If sufficient exposure is given and development carried out for contrast (neglecting density), very few plates need be wasted. The commonly accepted opinion seems to be that the silver is oxidised and dissolved by the reducer, and is then washed out of the film, but this, I think, is an error, as the following experiment will show:—If a plate is cut in half, one half reduced and the other half untreated, and then both are sulphide toned, the two halves will be found to be similar in density, showing that the silver is not removed from the film, but converted into a colourless transparent form, which resists the action of an ordinary developer as used in the Autochrome process. An after-bath of hypo does dissolve and remove the silver. There is room for investigation here. Is the silver first oxidised and then converted into sulphate which is only sparingly soluble in water, or does it remain as oxide, or is it converted to manganate; the changed salt being transparent, does it exist in a colloidal form? The compound formed seems to be fairly stable to light after clearing with metabisulphite, but may be slightly yellow in time; after an acid fixing bath there is, as one would expect, no change on exposure to light. These few notes may be of interest to some readers of the "B.J.," and perhaps someone with more time at disposal may care to investigate and express an opinion.—I am, dear Sirs,

Yours very truly,
E. S. Mapleb.

Clyde House, Edgerton, Huddersfield.
March 14.

REDUCTION WITH PERSULPHATE.

To the Editors.

Gentlemen,—I was interested in your editorial note (p. 134) on reduction with persulphate, but I think there is another cause of the irregular action of this reducer, and one which has not received the attention it deserves.

The point is dealt with by Lüppo-Cramer, in his "Kolloid-Chemie und Photographie," and I need make no apology for quoting his views *in extenso*. The translation is my own and makes no claim to elegance. In view of the length of the passage I have omitted the original text:

"I have shown that while thiosulphate itself is not adsorbed by gelatine, the silver bromide-thiosulphate complex compounds, produced during the photographic fixing process, remain in the gelatine as irremovable silver compounds, as soon as the proportion of thiosulphate to silver bromide sinks below a certain level. Also the silver gel. of the negatives obviously takes up silver bromide from the thiosulphate solution, and this becomes more noticeable with increasing concentration of silver bromide in the fixing bath."

"If sensitometer scales, after development in iron oxalate, are fixed in (1) pure 20 per cent. thiosulphate solution, and (2) each in 100 c.c. thiosulphate solution in which 1 to 4 gm. silver bromide have previously been dissolved, there remains by later removal of the silver a residue which becomes considerably greater as the silver bromide content of the fixing-bath increases. This is particularly noticeable when the silver is dissolved away in ammonium persulphate. After fixing in pure thiosulphate the reduction in persulphate takes place quickly and completely, but after fixing in a bath containing much silver bromide, the process of solution of the silver took place extraordinarily sluggishly, so much so that the dissolving of the silver only slowly commenced after half-an-hour."

"Undoubtedly this circumstance plays an important part in the practice of reducing with ammonium persulphate. Should the negatives in question have been fixed in a bath already containing much silver bromide, the reduction with persulphate sometimes does not take place at all. Also the presence of bisulphite in the fixing bath appears to play a part in this connection, since this considerably reduces the solubility of silver bromide in thiosulphate."

"Since, however, an after-treatment with pure thiosulphate of such a silver gel. charged with silver bromide partly removes the adsorbed silver bromide, it is desirable in photographic practice for a negative, which, owing to its gradation, is to be reduced with persulphate, to be once more re-fixed in pure thiosulphate before the reduction is undertaken."

I may say that I have always followed the instruction in the last sentence, and it is possibly owing to this precaution that I have not been troubled with the irregular action referred to in your editorial.—Yours faithfully,
W. B. Shaw.
29, Wednesbury Road, Walsall.

DR. RODMAN.

To the Editors.

Gentlemen,—On behalf of over 5,000 members of photographic societies represented by the "Club Photographer," I should like to be permitted to associate myself with the tribute you have paid to Dr. G. H. Rodman. He has shown himself a real friend not only to the R.P.S. but to the other photographic societies in the kingdom.

During my term of office as secretary of the Liverpool A.P.A., Dr. Rodman took the trouble to come down to give us his latest lecture, despite the pressure of his duties as president of the R.P.S. When, later, I invited him to assume the duties of judge of the scientific section of the "Northern" and also to give us another lecture, he assented willingly and made no trouble of the fact that this visit would entail a stay of some days in the Merseyside city. So highly is Dr. Rodman esteemed in Liverpool that the very rare distinction of honorary membership of the L.A.P.A. was conferred upon him.

Yet Dr. Rodman, while taking all pains to please us in Liverpool, by no means forgot his allegiance to the R.P.S., as he did some very active recruiting, and took back with him to London no less than five nominations on his first visit alone. I remember this distinctly, as I was his first victim.

He has, further, shown a keen interest in the progress of the club movement, and, as his Christmas message to all club photographers showed, his interest was not merely a surface expression but a very active association with all matters appertaining to photographic clubland.

He has carried out his exacting duties most efficiently, yet has left none but pleasant memories with those with whom he had associations, and I am only voicing the opinions of the whole of photographic clubland in wishing him a long life of continued usefulness.
—Yours, etc., Geoffrey E. Peachey,
Editor.

81, Dale Street, Liverpool, March 17.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors

H E.—The makers of the Sanderson camera are Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

M. F.—Your plan appears to be quite satisfactory. Sixteen feet is rather short for full-lengths, but we presume that you could take your camera through the workroom door and get an extra 3 ft. or 4 ft.

R J. A.—Something about your enlarging lantern is much out of the square. It may be that the front and the body carrying the negative holder are not parallel. Get a good set square and test all right angles between the lamp and the lens. Be careful that the negative carrier fits well in its grooves and that the negative is firm in its rebate.

A. H.—We have referred your inquiry to the author of the article on page 112, who informs us that fused calcium chloride is intended to be used in the formula. Crystals of calcium chloride would contain 6 molecules of H_2O, and might be detrimental to the collodion, as well as requiring a greater quantity, just over double, in fact.

P F.—If you have facilities for recharging them you can do very well with accumulators. For enlarging you would require, as a minimum, an 8 volt 1,000 ampere set. This with a 20-watt gas-filled motor headlight bulb would give you 40 c.p. for a good many hours. These lamps have a closely coiled filament, which should not be apparent on the screen.

B. H.—There are several systems of puttyless glazing. Messrs. Braby, 352-364, Euston Road, London, N.W.1, have one called the "Drop-Dry." This can be had with steel or wooden sash-bars. Another good system is that of the British Luxfer Prism Syndicate, 16, Hill Street, Finsbury, London, E.C.2. Either of these systems will be absolutely drip free, provided that suction is not permitted at the overlap of the panes.

C C. S.—We are afraid it is not possible to say why the hypo-alum bath in the lead-lined dish is so much less active than when the solution is used in an enamel dish. It is quite possible that the lead exercises a restraining action on the bath owing to combination with the sulphide, which is the active constituent of hypo-alum. We think that an enamel or earthenware dish should be invariably used for hypo-alum, and that is the general practice.

W. N.—Certainly you are at liberty to use the photographs for other purposes, it being presumed that you are granting reproduction in the journal for which you are writing only for the specific purpose of illustrating your article. If, however, you wish to dispose of the copyright outright, you must, as you say, cover yourself and your editor by excluding the right to reproduce the prints in connection with your article.

B H.—The celluloid discs of which you enclose samples are, in our opinion, absolutely useless as supports for any kind of photographs. To coat them singly with emulsion, even if they were clear, would be very difficult, and would cost more than ready-coated film could be purchased for. The only use that we can suggest is to make varnish or lacquer from them. There is a considerable demand for a clear celluloid lacquer for bright metal goods.

B. W.—Under the circumstances named we prefer the cascade pattern of washer, although, of course, it calls for more hand manipulation than the rotating drum or similar appliances. If the tanks are well made of a hard wood it is not necessary to give them any coating. There would be no objection to giving a coating of shellac varnish or good white enamel, but these coatings do not last for a very long time, and if the tanks are well made they are better without them. Messrs. Brodrick, Ltd., 50, High Street, Bloomsbury, London, W.C.2, make a very good cascade washer entirely of wood.

B. B. L.—Legally the copyright in the photograph which has been sent to you for enlargement is the property of your customer. Therefore, he is quite within his rights in ordering the enlargement and you are within your rights in doing the work to his order. We think that is as much as can be said. We do not think you are entitled to put your name below the coloured enlargement of a photograph by another photographer, even though the colouring is yours. By so doing the maker of the original portrait would, we think, have certain ground for action against you. Of course, unless you have the consent of your customer, you have no right whatever to exhibit any version of the portrait in your showcases without his permission.

G H. J.—(1) About the best general text-book on half-tone block-making is "Photo-Mechanical Processes," by W. T. Wilkinson, published by Messrs. Hamptons, Ltd., 12, Cursitor Street, London, E.C.4, price 4s., but no text-book is at all an efficient substitute for practical instruction in block-making. (2) We think your difficulty in getting half-tone blocks to come out well on news-print is that the block is made with too fine a screen. For blocks which are printed on paper, such as that used for the "B. J.," the half-tone screen should not be coarser than about 100 lines per inch. Of course a great deal depends upon the printer, and also upon the maker of the block. (3) The little French manual on air-brush work is not published in English.

E. M.—Whatever pattern of lamps you use you must have a diffusing screen, otherwise your negatives will be unevenly illuminated. If you use clear glass bulbs the form of the filament will be visible on the enlargement; with opal or ground glass globes you will have blobs. You will require two sheets of ground glass with a space of about 4 inches between them to get anything like even lighting. Four clear lamps with such a screen should answer fairly well. This method of lighting is very wasteful of current as compared with using a condenser. An inverted pyramidal reflector lined with silvered glass, with one lamp in the centre, would be more economical, but you must take care that the angle of the reflectors is such that the full power of the light reaches the ground glass.

W. V. L.—It is difficult to fix a price for the work you mention, but for your guidance we may refer you to the current "B.J. Almanac," on page 310 of which you will find a scale of prices for commercial work. In this 7s. 6d. is given for half-plate negative and one print. This, we think, is much too high for an order of 1,000 different subjects. A London trade firm advertises the low price of 1s. 7d. for making a quarter-plate negative and 11d. for a half-plate enlargement, making 2s. 6d. per subject, exclusive of collection and delivery. You must decide between these limits what price you think your customer will be willing to pay. If you are a member of the P.P.A. you would do well to communicate with the Secretary. We believe that the Society has discussed the matter, but, so far, has published no scale.

Contents.

SUMMARY.

By courtesy of Mr. T. C. Turner, we are able to publish the text of the short address given by him at the recent annual general meeting of the Professional Photographers' Association on electric light in portraiture. Mr. Turner describes the system he uses of confining the light within a given space by adjustable reflectors and also a form of portable half-watt lamp found of great utility for many pieces of work away from the studio. (P. 183.)

Professional photographers will be able to obtain season tickets for admission throughout the whole week of the Photographic Fair (May 1-6 next) at the nominal price of 1s. (P. 194.)

It is announced that Mr. Lang Sims has resigned the secretaryship of the Professional Photographers' Association, the Council of which have appointed Mr. Alfred Ellis in his place. (Pp. 193 and 181.)

The Professional Photographers' Association has finally authorised arrangements for the publication of a monthly "Record" (P. 193.)

In a recent address to the London Camera Club Mr. F. C. Tilney vigorously attacked present-day motives among pictorial photographers, and directed severe criticism upon the practice, prevalent among painters as much as among photographers, of imitating styles and mannerisms and neglecting natural beauty for the sake of many descriptions of "stunts." (P. 186.)

In the concluding portion of his paper on photographic tests of developers, Mr. J. I. Crabtree, of the Eastman Research Laboratory, gives examples of reports upon developers to be employed for various purposes. (P. 188.)

Defects which are often ascribed to a lens arise, in fact, from mal-adjustment of a camera. In a leading article we refer to the chief points which call for examination in this respect. (P. 182.)

It is announced that the paper making firms of Wiggins, Teape and Co. and Alex. Pirie and Sons have come to an agreement for a fusion of their interests. (P. 194.)

At the Royal Photographic Society on Tuesday evening last sincere regrets were expressed at the departure of Mr. F. F. Renwick. Mr. Ryde, of the General Electric Co., and Mr. Storr, of Ilford, Ltd., dealt with the properties and use of the new Osglim electric lamps. (P. 192.)

The great convenience of a light-tight cupboard running below the dark-room bench is the subject of a paragraph on page 181.

We cannot recommend the revival of methods of platinum toning of gelatine prints, since years ago, when this process was tried, the sepia results were found not to be of a satisfactory degree of permanence. (P. 182.)

Under the present Copyright Act, as under the previous one, "colourable imitation" is the touchstone of infringement. We refer to a test case which was notable at the time, and still supplies guidance in such cases. (P. 182.)

For removal of shellac varnish from negatives, methylated spirit with addition of a little ammonia is about the best means. (P. 182.)

Ex Cathedrâ.

New P.P.A. Secretary. As announced on another page, Mr. Lang Sims has resigned the secretaryship of the Professional Photographers' Association, the Council of which body has appointed Mr. Alfred Ellis in his place. We think the choice is an excellent one. Mr. Ellis has been a member of the Association from its very first inception, and was, in fact, its secretary during the first three years of its existence. For some considerable number of years past he has held the office of chairman of the Council, in which capacity all the affairs of the Association have come under his personal notice. Throughout the whole twenty-one years' existence of the Association no one member has been more assiduous in its support or has become so fully acquainted with the movements which from time to time have taken place within its membership. And further, the appointment has the good feature that Mr. Ellis is now able in his retirement to devote the whole of his time to the business of the Association, and is establishing, at his home, 2, Vinery Villas, near to the St. John's Wood station on the Metropolitan Railway, an office, where members can personally consult him in any matters of difficulty. For those duties, his life-long experience, technical and commercial, as a professional photographer makes him fully acquainted with the conditions and difficulties of his brethren, and, moreover, he carries in his mind the memory of schemes which in the past have been suggested but have been found impracticable. A suave man of affairs, whole-heartedly interested in the welfare of photographers, Mr. Ellis deserves, and we are sure will obtain, the support of the whole membership of the Association.

The Dark-Room Bench. If we were asked to name the fitting which is likely to be most appreciated by anyone doing a variety of work in a dark-room, we think we should give our choice to that construction of the working bench which provides a roomy light-tight cupboard running immediately below the bench surface. Its height need not be great—say, 6 or 8 inches—and its door or doors should be hinged along the lower edge, and secured, when in the shut position, by the convenient ball catch. This form of fastening allows of the door being instantaneously opened or closed by a pull or push. As a receptacle for sensitive negative or lantern plates in course of loading into holders or printers, a cupboard of this kind is a great convenience, the plates being most accessible, yet fully shielded from chance of fog. Also, a division of the cupboard may well be set aside for the reception of developing dishes in which, for example, under-exposures are being allowed ample time in a weak solution; or, indeed, for any plate in course of development, if there is the occasion to open the dark-room door. It goes without saying that the working bench itself must not admit the least drippings of solutions to

the cupboard; the otherwise excellent covering of cork lino is a sufficient safeguard in this respect. We have had such satisfactory experience of a dark-room bench embodying this cupboard that we are sure no one will find fault with us if they act on this recommendation in fitting or re-fitting a dark-room.

* * *

Platinum Toning of Bromides. Those who of late in this country and abroad have been advocating the after-toning of bromide prints with a platinum bath must certainly be ignorant of the efforts made some fifteen years ago to popularise this method. The papers and demonstrations of Mr. Winthrope Somerville, who, we believe, was the originator of the process and almost its sole protagonist, did all that could be done to persuade photographers to entrust their bromides to the tender mercies of platinum toning for the sake of the admittedly handsome sepia tone. Experience showed, however, that the process has certain serious defects. For one thing it has its likes and dislikes as regards the type of paper the prints on which it will tone. The gaslight prints of that day—it may be different now—were not readily susceptible to it. But its most grave disadvantage is the fugitive character of the toned prints. It appears inherent in the use of a soluble salt of platinum, with or without mercury, for the toning of a gelatine print that the permanence of the sepia-toned deposit is poor; that is, of a much lower order of permanence than the untoned image. And, to name a third drawback, the process was expensive enough when platinum was about £4 an ounce. At the present price of the metal there can be little inducement to use even a perfect process for such a purpose.

* * *

What is Infringement of Copyright? The use in the definition of copyright (in the Copyright Act) of the comprehensive phrase "in any material form whatsoever," makes it clear that the copying of a photograph in any process constitutes infringement. A wash or line drawing, an engraving and a three-colour reproduction from a photograph are equally infringements. In the Act of 1862 it was described as infringement "colourably to imitate" a work. This term is likewise used in the 1911 Act in defining an infringing copy. (See Section 35 of the Act.) Its use is of importance, since it provides against an infringer making such slight alterations as to protect himself against the charge of exact copying. For example, it prevents an artist making a drawing in his own individual style from a photograph; if the whole drawing or certain parts peculiar to the photograph, identify the photograph as the original from which the artist worked, the photographer has a claim for infringement. A judgment on this point was given in the case of Bolton *v.* Aldin. Mr. Cecil Aldin, the artist, had copied a photograph of a tiger by Mr. Gambier Bolton, the well-known animal photographer. The drawing was held to be a "pure copy and a very good copy" of the photograph, and as additional proof thereof it was shown that the tiger in the photograph had a cancerous growth in the mouth, which had been copied by the artist as part of the mouth itself.

* * *

Removing Varnish. Before attempting to remove varnish or retouching medium from a negative it is desirable to ascertain the nature of the solvent used for the gums, or considerable difficulty may be experienced. Fortunately, most negative varnishes consist of shellac and sandarac dissolved in alcohol, so that the coating may be removed very easily by the application of methylated spirit. The action of this is rendered much more effective by the addition of about five per cent. of .880 ammonia, which is in itself a solvent of shellac, and seems to leave the surface in a much better condition for intensification or reduction than plain spirit does. While in the spirit the surface of the negative should be well rubbed with cotton wool and wiped dry after taking out. A second bath of spirit, with or without ammonia, should then be given to remove the last traces of gum, and then the film should be soaked till all greasiness disappears. Retouching medium can be cleaned off with pure spirit of turpentine, rubbed on with cotton wool, using clean turpentine and wool until the surface appears quite even. Celluloid varnish may be removed with amyl acetate, alcohol or acetone. As the fumes of the first-named are injurious to some constitutions it should be avoided, if possible. In all cases where plain spirit is used it should be of full strength and not have been used for drying negatives.

THE LENS OR THE CAMERA?

We have recently had to deal with several queries concerning the alleged unsatisfactory performance of various lenses, and in each case it has been found that a want of accuracy on the camera or enlarger has been the cause. It may be assumed that, except through accidental damage such as may be caused by a fall or other violence, any lens bearing a name of repute is capable of covering the plate for which it is listed with sharp definition to the edges. If this is not found to be the case, a rigid examination of the camera should be made in order to find out whether the axis of the lens is at right angles to the plate or, in other words, whether the front and back of the camera are parallel with each other. A very slight error in this respect will seriously impair the performance of a rapid lens.

The method of examination must of necessity be varied to suit the different types of camera. With most stand cameras a good 90 deg. set square and a flat boxwood or steel rule are all the instruments necessary. The former is used to test the rectangularity of the front and back in relation to the baseboard in the vertical direction and the latter for checking the parallelism of front and back in the horizontal plane. The principal sources of error in the former position will usually be found in bent or strained struts, or in slots or notches, which either through faulty design or wear allow the moving parts to be clamped in an incorrect position. In the latter position the error is often due to wear in the rackwork allowing a tooth to be missed, and, perhaps, again picked up when closing the camera. Parallel cameras, in which the back is drawn out and clamped upon metal guides, should be very clearly marked on both sides at equal distances from the front, and great care taken in adjusting the back to these marks. It should be seen that the swing back of such cameras fits closely and accurately to the camera body when closed.

Hand cameras of the collapsible type are more difficult to test, as there is not a firm baseboard as a datum. The best plan is to use a good spirit level, say, six inches long, in the following way. Level a flat piece of glass upon three screw eyes fixed in a board or table top, taking care that the eyes are near enough together to come within the dimensions of the focussing screen of the camera. Remove the glass plate and put the focussing screen (which is, of course, in its groove) in its place, then lay the spirit level across the front cell of the lens. If the bubble remains central on being turned in all

directions the lens is truly normal to the surface of the screen. Errors will usually be due to strained struts or loose or broken pivots.

Reflex cameras, owing to their solid box-form construction, are only liable to get out of adjustment by way of the mirror. The best way to detect this is to set up a test object—a brick wall will do—which will cover the whole screen; then, after removing the hood, carefully examine the images successively, upon the top and back focussing screens. Any difference will at once be apparent.

Failing the discovery of any want of truth in the camera, the dark slides must be carefully examined. It is not enough to test them in the centre of the plate, as it is possible that this might be correctly situated, while one end was too near the lens and the other too far from it. Each corner must therefore be carefully tested with a simple depth gauge made with a screw passing through a stout lath. Every slide should be tested, for it has, at any rate, been our experience that extra slides fitted subsequently to purchase of a camera are not always accurate.

So far, we have sought for errors in the camera, but there are other quarters in which they may be found. A want of covering power which limits the use of the rising front is often due to too small an aperture in a before- or behind-lens roller-blind shutter. This can be proved by removing the shutter and attaching the lens to a temporary front for examination.

Lenses fitted in aluminium between-lens shutters should receive careful treatment, as pressure upon the lens cells may distort the shutter case and seriously impair the definition. This may be caused by closing a folding camera of the Kodak type without pushing the front quite home, or with a separately carried lens by forcing into too small a case. If at any time it is desired to fit a lens into another shutter, it is wise to let this be done by the maker of the lens, who will apply his usual tests before returning it.

What has been said of cameras applies equally to enlarging lanterns, the chief fault of which is the bad fitting of the negative carrier in its groove. This often allows enough play to cause considerable unevenness of definition, while weakness of the springs, which should bring the negative level, contributes to the same end.

ELECTRIC LIGHT IN PORTRAITURE.

[Following the annual general meeting of the Professional Photographers' Association, which was recently held, Mr. T. C. Turner, of Hull, gave a short lecture and demonstration of electric light in photographic portraiture. Through the kindness of Mr. Turner we are able to publish the text of this short paper. The occasion was one on which it was not possible for Mr. Turner to put before his audience a tithe of his wide knowledge of artificial light in the studio, gathered in the course of many years' practice with almost every system which has come into use, but nevertheless the very practical hints which he had to give, particularly on the usefulness of a portable half-watt installation, will certainly be of value to those having the occasion to undertake portraiture away from the studio after dark. The portrait of Sir Landon Ronald and also the profile study of a lady were taken with the portable outfit which is described and illustrated in Mr. Turner's paper.]

The last occasion upon which I had the privilege of addressing you upon the subject of artificial lighting in photography was at the second Congress held at the Horticultural Hall on May 16, 1911, a report of which the "British Journal of Photography" was good enough to give *in extenso* a few days afterwards.

The methods we had in use up to that period (eleven years ago) were, the open carbon arc (improved from Van der Weyde's time by running four pairs in series), the enclosed arc, the ordinary carbon filament lamp brought to high incandescence for a brief period by cutting out a resistance in the circuit, known as Adamson's lamp, and, lastly, the "Cooper Hewitt" Mercury vapour lamp, with various modifications, such as the "Silica" lamp of the Westinghouse Co. Now some of these systems are still very much in use, but in the exceedingly limited time available this evening I do not propose to touch on their special advantages for certain definite purposes—as they are pretty generally recognised.

The Half-Watt or Gas Filled Lamp.

In the year after that second Congress of ours, an event of far-reaching importance to photographers occurred with the introduction of what is known as the ½-watt lamp, which, in 1913, was already installed in a few studios. As many of you may know, these lamps are filled with an inert gas, those of large wattage with nitrogen, and the smaller sizes with argon. During the war the British makers were not allowed to fix up the elaborate plant necessary for the manufacture of this gas, and many of us were forced to obtain lamps of high actinism "made in Holland." Happily, now, the British product is unequalled.

The advantages which came with the half-watt lamp were these:—

The grime and dust of the consumed carbons could be avoided; also the need for constantly renewing them. Risks of fire were lessened and once properly installed the lamps were safer for the non-technical operator to manipulate, and the sitter felt more at home under the warmer light than under the colder effulgence of the arc. But the greatest of

Fig. 1. Photograph of Mr. T. C. Turner's studio, showing adjustable reflectors mounted on rollers placed on each side of the half-watt installation and movable transversely.

the benefits we gained with the introduction of this lamp is the better rendering of tone values, and the much increased power of control in lighting our sitters.

As in the making of an artistic picture, the chief thing is what we are able to leave out, so in this matter of lighting

the advantages lie all on the side of that illuminant which can be most readily kept from flooding the room with undesired detail and yielding the greatest variety of effects. You may say that the actinism of the *arc* is so much greater, and that for a given number of watts the effect is far more

Fig. 2.—Showing reflectors in the rolled up position.

powerful than with the same current going through half-watt lamps.

That is largely a question of the manner in which the two systems are employed. The arc requires much more diffusion, needs to be used at a greater distance from the sitter, and is less amenable to shading control than the gas-filled lamp. I have brought here to-night a small portable outfit, which anyone with a little assistance from tinsmith and ironworker can put together at quite small cost. You will find it contains many essentials of the permanent studio installation, but in miniature.

The supporting pole has a sliding rod—one of the old curtain poles with a fairly heavy circular plate and ball castors makes an excellent stand. The rod is pierced for pegs, and has a 5-ft. projecting arm easily placed in position for carrying shaded lamps, which control the lighting of the sitter's hair and shoulders. On the upright

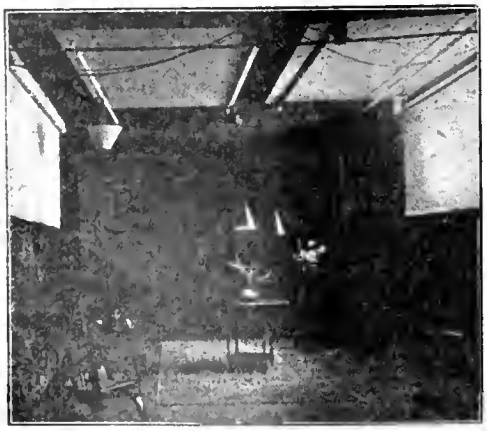

Fig. 3.—Photograph of the studio for open lighting. The view shows the Meccano carriages for 1,500-watt lamps running on the T-irons. Small hooded lamps can be brought down from the ceiling, and likewise run on a Meccano carriage which travels on a stretched wire. This electric fitting is found very useful for lighting hair.

pole are grips and rods which carry slightly larger shades (about 12 × 10 in.).

The handle is made hollow so that the lamp and shade easily come off the rod, and the exposure made with lamp in hand instead of on the pole. The background may be lighted with one of the spare lamps, the whole object being to obtain control of the direction the light is to fall and to work pretty close to the model.

The shades are painted inside with white flat Japan, the lamps themselves acid-obscured at the front, or diffusion

Fig. 4.—Photograph showing system of main lighting with three 1,500-watt lamps. The white background is shown as used for sketch portraits, being lighted by a G.E.C. flood light lamp shown at A.

secured by fitting on a sort of biscuit-tin lid stretched with China silk or translucent paper held in position with a spring in the lid. Matt varnish for "frosting" should not be used, as it quickly turns yellow.

Lamps should be fitted into the screw-in type of holder, and not the bayonet form, as great heat is generated by the "half-watt" lamp and the spring contacts rapidly weaken.

Fig. 5.—Portrait of Sir Landon Ronald taken by Mr. T. C. Turner with the portable lamp described in his paper, in conjunction with a certain amount of general diffused lighting.

Mr. Turner then demonstrated the manner of working with 200-watt lamps in the shades, and said one of the advantages of such a "pocket edition" of a lighting apparatus was that it could be worked off the ordinary house wiring and from a 5-ampère switch, if the switch was a sound one of good pattern—many, of course, being badly made and liable to arc.

In referring to the permanent appointments of a studio

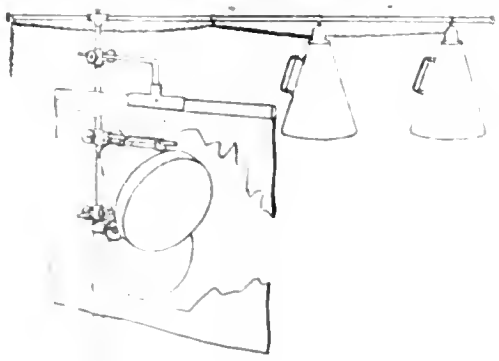
required for large groupings and single-figure studies, Mr. Turner said he believed in methods of quickly enlarging and reducing not only his *lighting* area, but his *reflecting* area; in other words, he made a large studio or a small one by carrying in or out reflecting walls of whitened canvas hung on rollers from "T" iron supports. Many photographs were exhibited to illustrate this studio method, and the types of lighting obtainable. No small interest was shown in the use of "Meccano" carriages to support the lamps running on the "T" irons, and from iron wire stretched from the top of the studio. It is a novel and effective device worked out by Mr. Eric Turner.

Mr. Turner particularly explained that these reflectors were the usual white grounds. When employed in a lowered position he was careful not to let them come below the level of the top of the head, otherwise an unpleasant appearance was produced in the eyes of the sitter. Also, when a lamp was burning on the right side, the corresponding lamp on the left side requires to be switched off, otherwise there is lack of modelling. Further, great care has to be taken that no light from either the ceiling or the sides shall fall towards

Fig. 6.—Portrait of a lady taken with the portable apparatus. This photograph illustrates the use of the shades and the manner in which the background is kept a natural dark shadow

the lens. This is easily prevented by angling the reflectors somewhat, that is to say, inclining them towards each other so that they form the sides of a triangle the point of which is in the neighbourhood of the camera. A screen may also be used with advantage, narrowing the opening towards the "box of light."

One of the advantages of this false ceiling is that with the coming of "summer time" one section easily slips partly



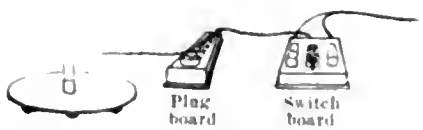


Fig. 7. Diagrammatic sketch showing the portable half watt lamp described by Mr Turner

back over the other, leaving plenty of daylight through the ordinary skylight. Under this arrangement daylight negatives may be readily made as and when the light permits, and the lamps employed for Rembrandt or other fancy lightings. Mr. Turner's experience has been that the arrangement allows of a great amount of control in a large studio, such as his is, and as are many of those built years ago when the chief aim was to get a flood of light.

The General Electric Co., of Kingsway, kindly lent the half-watt lamps used for the demonstration, and Mr. Turner said this great firm was always interested and helpful in the development of apparatus as applied to photographic purposes. At the moment he was experimenting with one of their new 500-watt "flood lights," which promised to be a useful accessory for special work.

Messrs. Marcus Adams, Corbett, Speaight, and Banfield contributed a most interesting discussion which followed the demonstration, and the president, in proposing a vote of thanks to Mr. Turner, said he was impressed by the great instructional value which had resulted from the remarks of all the speakers of the evening, treating the subject, as they did, from so many points of view.

PHOTOGRAPHERS AND THE G.P.O. A curious case of G.P.O. idiosyncrasy, and one of particular interest to photographers, is reported in the daily newspapers. An establishment has for many years been sending out circulars and proofs in envelopes or wrappers with the name and address typed across the width and not the length of them, the typist doing them width-ways because of the typewriter not taking the envelopes and wrappers length ways. Last week, however, a batch of circulars and proofs were held up by the authorities because of the matter being, it was said, incorrectly addressed. Investigation proved, however, that nowhere in the official instructions could the sender find any reference to the manner of address nor shape of the envelope, and after being held up for three or four days the matter was allowed to go through the post as usual. A correspondent informs us that this idea concerning cross-addressing is common in many suburban post offices, many of the young counter hands having but the most vague ideas as to what is in and what is not in the official handbook. Economy is now the order of the day, continues our correspondent, particularly as regards postal, telephone, and telegraphic business, and it is surprising that more business houses do not have code addresses, and so save money. The latest returns show that about 133,000 firms in the United Kingdom are using code addresses, but photographic firms are not so keen about them as they might be. In London alone there are 33,400 persons who have paid the £2 fee for the use of code names, and Sell's directory of code words of the Kingdom just issued shows the ingenious ways in which the trade have made this firm's name or business into a suitable code. Beside the usual code words for telegrams the "round number" for telephones is also much in demand. Blocks of round numbers are kept specially for busy lines. People wait for months to get hold of a good one, and some firms declare that they owe a good deal of business to the round number call. Houghtons, Ltd. (Holborn 2500) is a good example of a round easily remembered number, and special efforts were made some years ago to get it.

THE NEED IN PICTORIAL PHOTOGRAPHY.

[The following address recently delivered by Mr. F. C. Tilney at a meeting of the London Camera Club reaches us without a title. We have given it that which appears above, thinking it one to which Mr. Tilney would scarcely demur. That the author was in a castigative mood when he committed his words to paper is sufficiently evident; yet when allowance has been made for a special vigour of expression, it is still seen that the themes of the papor are those which have always dominated Mr. Tilney's teaching, viz., the plea for the study of the artist's temperament and a relentless hostility to the modern exaltation of all descriptions of mannerism. Photography in particular can benefit by such healthy wind of criticism as this.—EDS. "B.J."]

ALTHOUGH this is a camera club I feel that its activities are so multitarious, and the tastes of its members so catholic, that something in the nature of an apology is due from me for proposing to talk about my old, one and only—*art*. If nothing but photography were thought of within these walls my subject might still be considered somewhat an alien one by those who maintain that art is one thing and photography another. But I believe that there is a still further dilution of art in this club. It is whispered to me that the click of the billiard ball is a more frequent sound than the oaths of the developer in the dark-room. But perhaps that only shows the restraint and good behaviour of the latter.

At any rate, here I am, with that tedious old subject before you again. How perennial it is—how immortal! There is no word more constantly on the lip, and no subject less understood.

When the photographer *is* an artist there is nothing to choose between him and a painter. They both look out on Nature in the same way. They feel and they know. And they know when others cannot feel, but only pretend to. The true artist can only see and feel in one way, and that is his own way. Be he painter or photographer he can only feel through his own consciousness; and the man that has to adopt the ritual of others as an outward credential when he has nothing within himself is he that cannot and never will make the true artistic demonstration.

Modern painting is, as we know, teeming with humbug that is all trick and observance without anything of the divine efflatus behind and within it. The teeming humbugs find it easy to pass for the real thing among those who do not know. The facility is due to modern journalism, which thrives only on stunts. Stunts make sensation. The humdrum of real art does not. Therefore the critics (pardon the misnomer)—I mean the penny-a-liners—boost the stunters and everybody is happy except the artists.

The photographer when he is not an artist—and mostly he isn't—adopts the outward observances of the painters, both the stunters and the good sort, too. For not having the real Freemasonry of Art he finds it difficult to discriminate between the real and the sham. He finds, too, in his turn that if he adopts the style of the Futurist or the Cubist he stands a chance of getting some recognition from the penny-a-liners.

Time was when this tendency was pretty bad. But, thank God, the days of Coburn at his worst, *et hoc genus omnes*, are over. The stuntists in photography have found that they cannot make it pay, and I, for one, have done my little best to queer their pitch.

But there is still a vast amount of humbug going forward; although it is not of the shameless sort that puts on motley and stands on its head in the market-place. Quite a lot of the humbug is harmless and excusable—the result of a sort of auto-suggestion more than anything else. A man larks about with his boy's toy camera and gets bitten. "Hm!" he says. "I think I'll get one myself." He buys a good one, joins a local club, exhibits in the Beginners' Section, gets promoted in time, wins certificates, and eke a medal, and the hat thereof knoweth him no more. It is a pretty little epic, but it represents truly the course of art training of the average photographic "artist." The reason he gets swelled head is that he mistakes his medal and other awards for proofs of genius. He does not realise that what he does anybody could do with a little practice and a little teaching of the tricks of composition picked up in the two-penny journals. He refuses to see that hundreds of thousands *are* doing it.

I do not say that there are not grades of excellence in this accomplishment, nor that the best results of those who have rolled in the art-pollen are not beautiful things. But I do say that the impulse does not come from within once in a thousand times—it comes from without—is adventitious. It is indeed the observance—docilely, admirably learnt and unimpeachably practised—of others' practice.

But I have no quarrel with such photographers, because, as I have admitted, the best of them produce admirable things. Whether the whole of the credit is due to the photographer or to happy fluke and the perfection of apparatus is another question. With fool-proof cameras and developing tanks, and with experts to do the enlarging, it is only possible to make bad prints by absolutely bad selection of subject and subsequent personal control in the printing. And, if you think of it, it is on these points that most of the bad work rests.

My quarrel is with those who having all the present-day advantages are yet unable to catch a breath of that proper and personal art feeling that would, under such advantageous conditions as photographic execution enjoys, bring off a masterpiece every time. Why should they ever fail?

The truth is they are content with the lotter of Art and seek not the spirit. They think they know because they talk glibly the art jargon. They think, too, that their method of teaching one another is all that is needed. They see nothing anomalous in the fact that the blind should lead the blind.

If they would but learn, or learn to teach themselves, instead of attempting to thrive on the mutual criticisms of the postal album and the local exhibition, they might some day be really converted, in which case the observances they now practise would have something of meaning for them.

For I believe that Art can overwhelm a man, just as the rabid Salvationist believes that Divine grace can suddenly overwhelm a man—perhaps not quite so quickly as in the latter operation. We can't make artists by sudden conversion at revivalist meetings; but we *can* make them, if they will give themselves to the business. Art is only a way of looking at things—nothing more. The Beauty sense is in us all; it is a germ in various stages of development, and sometimes not developed at all.

I quarrel with the photographer who looks at pictures and copies mannerisms from them; content to think that by so doing he is making artistic pictures. For my point is, that he copies these styles and mannerisms, not because anything in them gives him a thrill of joy; but because he believes he will be mistaken for an artist. Every manner or style that develops into a trick loses caste with the true artist; and if the photographer were converted he would no more think

[illegible] making pictures by [illegible] than he would [illegible] flying. Indeed, he would [illegible] days much [illegible] flying.

One of the most regre[illegible] of [illegible] tendency to teach the [illegible] the painte[illegible] photographers as though th[illegible] gospel of [illegible] mention a flagrant case.

One of the recent stun[illegible] painters [illegible] surface stunt. The argumen[illegible] is thi[illegible] a two-dimensional thin[illegible] well, then [illegible] represent things as three-dimens[illegible]. Was there ever [illegible] folly? We paint things [illegible] height and breadth [illegible] depth; but we must always [illegible] the [illegible] picture surface has only height and breadth! Where is the [illegible] idiot who wants reminding of this? Who looks [illegible] landscape and attempts to [illegible] it?

This is a piece of [illegible] evolved by painters who [illegible] the three-dimensional [illegible] could not make things [illegible] round if they tried, and [illegible] skill to represent [illegible] between vertical [illegible] unfortunates have [illegible] virtue of necessity by adopting [illegible] method of [illegible] the kind that employs [illegible] no [illegible] cast shadows. The [illegible] method was [illegible] only to the practice [illegible] great Art [illegible] of the ages was a fact [illegible] could [illegible] upon, so the critics [illegible] the period [illegible] called this confession of weakness [illegible] a heaven-sent [illegible]. All are from antiquity [illegible] with all the [illegible] great names—Pheidias, [illegible] Angelo, R[illegible], Rembrandt, Rubens, Claude, [illegible]arth, Reynolds [illegible] these were wrong, poor [illegible] who had [illegible] and bashed their heads against a three-dim[illegible] fallacy. It was left to twentieth century ingenuousness [illegible] upon the true idea—flatness.

In their ignorance these [illegible] of this idea [illegible] Velasquez and Whistler [illegible] the sublime [illegible] flatness—Velasquez, the man [illegible] all others who [illegible] ambient enveloping a figure [illegible] Admiral—the [illegible] example of the advocates—surpassed [illegible] Philip IV. [illegible] picture momentarily for the [illegible] himself. These [illegible] not see that the flat [illegible] black costume [illegible] are the true impression of a figure standing in [illegible]. They cannot see that Whistler, an arch-[illegible], for all his genius, painted in the same flat Velasquez manner without arriving at anything like the [illegible] exemplar; that Whistler's flatness was [illegible] borrowed from Velasquez [illegible] mixed up [illegible] the decorative formulas of Japanese art. What [illegible] these two painters [illegible] for the theory [illegible] pictures should be painted in such a way as not to [illegible] spectator to forget that [illegible] sheet of [illegible] thing of two dimensions.

This trick is being taught to photographers. [illegible] one quality in which the photographic picture [illegible] three-dimensional [illegible] going [illegible] relief, we can find in [illegible] executed photographs convincing evidence [illegible] near and [illegible] it represents. [illegible] have [illegible] certain teachers [illegible] eliminate [illegible] strength of photographic [illegible] and [illegible] prints that [illegible] suppose Velasquez [illegible] and which they believe [illegible] characteristic [illegible] brilliant genius of Whistler. [illegible] knows [illegible] and relief have been [illegible] of decorative [illegible] Renaissance [illegible] excelled in it. The eighteenth [illegible] ornament [illegible] in engraving [illegible] popularly [illegible] in masterly strength [illegible] roundness [illegible]. The old masters [illegible] Impressionists [illegible] Water-Colourists [illegible] great school [illegible]

[illegible] that true dimensional [illegible] normal human vision. [illegible] of painters overstep [illegible] extremity where [illegible] argument for [illegible] on Na[illegible]

[illegible]

the works of others. His works are, once he has learnt the language, works of art.

Why should not the mass of photographers rise to this? Why should they not attain to the true vision and feeling? Could they do so, there would be little risk of their producing mannered work, aggressive designs, shrieking silhouettes, jazz patterns, false tonality, anomalies of light and shade, and "beautiful facts." Above all the supreme sin would be washed away—the effect of thunderous gloom which shrouds the enlargement, the bromoil and the oil print. We should more often see a healthy and naturalistic length of scale, fewer specimens of that mechanical harmony of tone which comes automatically from keeping all tones of nearly the same strength. A ruse of safety for those who cannot manage contrasts. We should see something of the character and power and beauty of form in skies instead of the nondescript light patches that are proffered for clouds in bromoil prints. The best skies occur in the under-exposed views of the beginner. If the bromoiler worked from what he knew and felt instead of what he swanked, he would not ink up his shadows in a wrong order of gradation, so as to mix up his planes. Nor would he be blind to nobility of subject. He would not, for example, find in our splendid streets, with their gorgeous largeness of tone-schemes, their sparkle and quality, nothing to inspire him but the wheels and axles of motor-buses. He would give the iron bridge a rest, with its black and straight girders. He would suppress the eternal pierrot and ballet-dancer. He would, indeed, see that arresting subject-matter is no help to quality, but rather a hindrance to artistic attractiveness; for great art makes sublime the commonplace.

In short, what pictorial photography needs badly is a mental and moral re-birth. What progress there is is that of the dealers, who keep glutting the market with printing-papers bearing a multitude of fancy names which defy the memory. But what difference, artistically, does such progress make? Any old paper will serve the purpose of a man who has something to say and can say it.

I have not treated you to-night to a dissertation upon technical art matters. There is quite enough of that sort of thing done, and it has its abuses as well as its uses. What I have tried to emphasise is the fact—all too seldom touched upon—that art in pictorialism, as in everything else, is expression of emotion; and that if there is no emotion, there is obviously nothing to express. It is then that picture-making has to fall back upon mere sophistications of Form without inspirations of Content.

It is this inspiration alone that can quicken pictorial photography, and put it, as it should deserve, on the level of the graphic arts. The inspiration is impossible without sensitiveness to beauty; and as all beauty is based on principles that are found in Nature, the photographer must cultivate Nature before he cultivates Art. To proceed the other way about, as is now done, is futile. Art is understood automatically when we apprehend beauty in Nature, for Nature teaches the principles of Art and drives us to pictures. Responsiveness and sensitiveness must be developed; and this can be done by systematic training of the eye. At least, that is the common phrase; but, of course, it is not the eye at all; it is the training of the mind to adopt a certain and peculiar attitude towards natural phenomena. But this is quite a different thing from what is understood by an art education; it is, in reality, a general education—directed towards the peculiar psychological culture that is characteristic of the true artist.

You will think that I have been presumptuous and aggressive. I offer neither denial nor defence; for it was my intention to stir you to a discussion. You may turn and rend me; I shall still hold together sufficiently to substantiate the arguments I have advanced. There is only one word I would say to shield myself from your wrath and vituperation: it is that you will give me the credit of recognising that some of the best and most artistic pictorial photographers are members of this Club, and two or three are painters as well as photographers.

My tirade is directed against the rank and file of pictorialists who go on doing wrong things in a fool's paradise from which they are too blind and too self-satisfied to be led away. Many of these enjoy appreciable reputations in the photographic world, and nobody ever attempts to open their eyes.

It is my wish to exalt photography, to cleanse the Augean stables, to imbue it with a pure purpose which shall give it the status amongst the arts that it should long since have enjoyed; and I have taken the only means I know of. My voice for over twenty years has been a voice in the wilderness. I am still preaching in that wilderness, but the willing ears are few.

Perhaps my mission may be thought one of unpardonable arrogance and presumption. I may have no right to assume the rôle of mentor. If this is so I must be forgiven, for nobody yet has hinted this to me; and if I am spoiled, I am spoiled by a too indulgent encouragement from those who perceive my motives.

F. C. TILNEY.

PHOTOGRAPHIC METHODS OF TESTING DEVELOPERS.

[A communication from the Research Laboratory of the Eastman Kodak Company, reprinted from the "American Annual of Photography." The Elon mentioned, it may be stated, is metol (monomethyl paramidophenol sulphate) of Eastman manufacture.]

(*Concluded from page* 172.)

Reports on Developing Formulae.

For practical purposes developing solutions may be divided into five classes as follows:—

1. *Developers for average work.*
   a. Negative developers (tray and tank).
   b. Paper developers.

Tests on these developers should include developing power, life, colour of image, fog, etc.

2. *Developers for under-exposed negatives.*

These developers should be tested against the following formula, which is the best present known formula for under-exposure work:

	Metric.	*Avoirdupois.*
Sodium sulphite	60 gms.	2 ozs.
Elon	16 gms.	250 grs.
Hydroquinone	16 gms.	250 grs.
Caustic soda	10 gms.	150 grs
Potassium bromide	10 gms.	150 grs
Water to	1 litre	32 ozs.

Then add wood or denatured alcohol 50 cc

If this developer gives too much contrast, reduce the negative with ammonium persulphate.

Preliminary tests should be made on flashed film, giving such an exposure that a just visible deposit is given by the above developer in, say, 3 minutes. If the formula to be tested compares favourably with the above, a final test should be given by cutting a camera exposed film in two and developing one-half in each developer.

3. *Contrast Developers.*
   a. Short life type.
   b. Long life type.

The best contrast developer known to date is the following:—

Solution A.	*Metric.*	*Avoirdupois.*
Sodium bisulphite	25 gms.	375 grs.
Hydroquinone	25 gms	375 grs.
Potassium bromide	25 gms.	375 grs.
Water to make	1 litre	32 ozs.

8. See "Elementary Photographic Chemistry," p. 48 (Eastman Kodak Company).

Solution B.

Caustic soda	45 gms.	1½ ozs.
Water to	1 litre	32 ozs.

Use equal volumes of A and B.

This developer will not keep, so that for tank work a comparison should be made with the formula given in the report below, which has much better keeping qualities, but does not give as much contrast as the formula above.

The following example illustrates the method of testing contrast developers :—

Report on a Process Developer Formula for Tank Work.

The formula submitted was compared with the Eastman process Elon-hydroquinone tank developer, the formula for which is as follows :—

	Metric.	*Avoirdupois*
Sodium sulphite	75 gms.	2½ ozs.
Elon	1 gm.	15 grs.
Hydroquinone	9 gm.	135 grs.
Potassium carbonate	25 gms.	375 grs.
Potassium bromide	5 gms.	75 grs.
Water to make	1 litre	32 ozs.

Tests were made on flashed process film, developing for five minutes at 70 deg. F., and the tests repeated at intervals, until on standing in open trays the developers were exhausted. The results were as follows :—

	1st Day.		*2nd Day.*		*5th Day.*	
Developer.	*Density.*	*Fog.*	*Density.*	*Fog.*	*Density.*	*Fog.*
Test formula	1.14	.05	.74	.05	.00	.00
	Developer : Reddish brown.					
Eastman formula	1.62	.09	1.43	.06	1.03	.04
	Developer : slightly yellow.					

The above results show that the developer submitted is inferior as regards developing and keeping power to the Eastman formula.

4. *Ultra Rapid Developer for Recording Paper.*

With many scientific recording instruments the record is made by means of a beam of light reflected from a mirror on to a travelling band of photographic paper. It is often necessary to develop this record almost instantaneously, and for this purpose the following formula is recommended :—

	Metric.	*Avoirdupois.*
A. Sodium sulphite	15 gms.	225 grs.
Elon	10 gms.	150 grs.
Hydroquinone	10 gms.	150 grs.
Sodium sulphite	60 gms.	2 ozs.
Water to	1 litre	32 ozs.

Then add 50 c.c.s of wood or denatured alcohol to keep the Elon and hydroquinone in solution. The sulphite is added in two portions to facilitate solution of the Elon.

B. Caustic soda	25 gms.	375 grs.
Water to	1 litre	32 ozs.

Use equal volumes of A and B.

When comparing a new formula with the above, tests should be made on flashed sheets of paper and preference given to the developer producing the greatest density in the shortest time, providing the keeping properties are satisfactory.

5. *Deep Tank Developers for Motion Picture Film Work and Amateur Finishing.*

Satisfactory developing formulæ in this class are more difficult to work out than any other developing formulæ because deep tank developers must fulfill so many conditions, as follows :—

(*a*) The developer should give a negative of fixed contrast in a given fixed time. An average time for developing motion picture negative and positive film is five minutes, and fifteen minutes for amateur finishing. The time fifteen minutes is convenient because it takes about ten minutes to load a new rack with films. The time of development is easily adjusted by diluting the developer or making it more concentrated.

(*b*) The keeping properties should be satisfactory as regards growth of fog with age, non-staining properties, and exhaustion. After the developer has been used for some time, the concentration of potassium bromide, which is formed as a result of conversion of the silver bromide emulsion to metallic silver, increases, so that if the developer contains much hydroquinone, which is very sensitive to bromide, shadow detail in the negative is lost. Pyro Elon and Ortol are less sensitive to bromide and should therefore predominate in a negative developer. Pyro oxidises rapidly and gives stain unless an excess of sulphite is added, which in turn tends to produce fog. For motion picture positive work the effect of the accumulated potassium bromide is of less importance, since this can be compensated for by increasing the printing exposure.

In tank work, as the developer becomes exhausted as a result of performing useful work, it is customary to increase the time of development by about one minute per day so as to maintain a constant contrast of the negatives.

Tank developers should be given a thorough exhaustion test by developing camera exposed or flashed films in a deep glass tank containing about half a gallon of solution, a sufficient number of films being developed daily so as to correspond to an average daily run in a fifty or one hundred gallon tank. Graded strip tests should also be made daily and developed to a given density contrast, the density of the lowest steps which area measure of the detail giving power being carefully noted.

(c) The alkalinity should not be excessive; otherwise, the acid fixing bath soon becomes neutral as a result of the neutralisation of the acid by the alkali in the developer carried over by the films.

The following example illustrates the method of testing tank developer.

Report on a Deep Tank Developer Formula for Amateur Finishers.

The formula submitted was tested against the standard formula first developing flashed sheets of NC film for 15 minutes at 70 deg. F., the tests being repeated after allowing the developers to stand in open trays over night and diluting to the original volume to compensate for evaporation. The results were as follows :—

	1st Day		*2nd Day*	
	Density	*Fog*	*Density*	*Fog*
Test Formula	1.50	.32	1.40	1.30
Standard Formula	1.60	.20	0.20	0.15

This preliminary test showed that the developer submitted has excellent keeping qualities, so that further exhaustion tests were made by developing the equivalent of five hundred rolls of film per day in fifty gallons of developer for a period of five days. Daily tests were made on graded strips noticing carefully the lowest density and the density contrast. The results were as follows :—

	1st Day				*5th Day*			
	Densities		*Density*		*Densities*		*Density*	
	2nd Step	*6th Step*	*Contrast*	*Fog*	*2nd Step*	*6th Step*	*Contrast*	*Fog*
Test Formula	0.31	1.60	1.29	0.14	.21	1.21	1.10	0.10
Standard Formula	0.30	1.20	0.90	0.13	.20	1.01	0.81	0.13

The above results show that although the test formula has excellent keeping properties, as the developer becomes exhausted it loses its power of rendering shadow detail. The developer costs twice as much as the standard formula, but the cost per unit of work is less, since its active life is greater.

Precautions to be Observed when Testing Developers.

1. Make all tests on film having *the same emulsion number.*

2. The flashed strips or exposed graded strips must all receive *the same exposure*, especially when making keeping tests at daily intervals. To insure this the exposing lamp should be placed in circuit with a volt meter, and the voltage maintained constant at, say, 110 volts. It is also advisable to adjust the time of exposure so that the exposure required is at least 20 seconds either by varying the distance of the printing frame from the light source, or by placing one or two sheets of opal glass between the lamp and the exposing frame. If an error of one second is made in exposing, the error will then be only 5 per cent., while if the exposure given is two seconds and an error made of only one half second the effective error would be 25 per cent.

3. The developers to be compared must be at *the same temperature.*

Tests at daily intervals in order to be strictly comparative should be made at the same temperature, although the temperature usually varies only slightly from day to day. Unless a thermostat is available it is better to make the tests at room temperature (which should be stated), providing the temperature of all the test developers

9. See "Booklet Reproduction Work with Films," p. 10 (Eastman Kodak Company).

is the same, rather than attempt to adjust the temperature to a standard temperature.

4. *The degree of agitation of the developer* relative to the film when making the tray and tank tests *should be constant*, because when the film or developer is agitated the developer in contact with the surface of the film is frequently renewed and the development is much more rapid than when the film and developer are stationary. Handling of the test strips is much facilitated by pinning across a wooden frame with the aid of glass push-pins.

5. When making the exhaustion tests the sheets of film used for exhausting the developer should be half flashed, that is, one-half of the sheet should be unexposed so as to represent an average exposed negative. An average rate of exhaustion is the equivalent of ten sheets of 3 x 10 film per gallon of developer per day for five or ten successive days

As each successive daily test is made there is a loss of developer from evaporation and from absorption by the gelatine film. If the tanks are covered the loss by evaporation will be negligible.

J. I. CRABTREE.

Photo-Mechanical Notes.

System in Half-Tone Operating.

JUDGING from recent communications on the subject, the technique of half-tone negative making is still apparently as much a matter of uncertainty as it was 20 years ago, and, realising the advantages of systematic working, several investigators and inventors have introduced certain apparatus and working methods with the object of standardising workshop procedure, so as to make for a more regular product from the half-tone operator.

We have had the system as worked out by W. J. Smith and E. L. Turner, and crystallised in the screen and stop indicator marketed by Penrose and Co. We have also had the Douthitt diaphragm control system introduced from America, and which is on the market at a price which certainly does not err on the side of cheapness

Both of these systems are designed with one object in view, that is, the simplifying of half-tone operating and the standardising of half-tone screen negatives, and it is possible, by comparison with the guesswork and rule-of-thumb methods still greatly in vogue, that they have both succeeded up to a point, but speaking quite without prejudice, I believe that both systems fail in several very important particulars. I have not seen the Douthitt system in use and therefore I may be speaking without my book, but I have studied the article by Ralph Grenell in the "Process Year Book," and if the stops and screen distances in his table C are the basis of the Douthitt system, then I can only say that it fails equally with the Smith and Turner system in its inability to make a half-tone negative from any given copy and extension, and with all screen rulings with the same stop and the same exposure. If this is not possible with any operating system, then, in my judgment, it fails.

The screen distances as advocated by Smith and Turner are based upon the usual equation with a stop proportion of 1-64, and they will probably produce satisfactory negatives, but not with the same stop and exposure for different screen rulings. For example, a certain stop, say, //32, is used with a 50-line screen at 16 mm distance, and a certain effect obtained. If a 200-line screen is used at 4 mm. distance, as advocated, then a stop half the size, *i.e.*, *f*/64, must be used to obtain a similar effect to the 50-line screen negative. This at once introduces a different exposure scale, which would vary with each ruling, and is not at all a simple problem, as the exposure in screen operating is not in proportion to the square of the aperture, as in ordinary photography. Exposure should be constant with all screen rulings, and all camera extensions, light and copy being equal.

For many years past writers upon this subject have accepted the pin-hole theory, but if this is correct, it can only be so with one size of stop at any one extension, and yet the same people who accept this pin-hole theory immediately advocate the use of two or more different sized stops in making a single exposure. If the screen distance is correct for one stop, it must be incorrect for any other, or, if the screen distance is set for a stop midway between two in use, it is incorrect for both, hence we have all the rigmarole of cutting and faking, and, as a consequence, false gradation. Why do operators find it necessary to use several stops to secure satisfactory dots at both ends of the scale? Because the screen distance is incorrect for either stop, or because the stops selected are incorrect for the tone scale of the copy. The only possible way to obtain correct gradation in a screen negative is by the use of one stop only.

It must be clearly understood that the whole of my remarks apply to dry-plate negatives; I have no interest in wet-plate half-tone operating, having cut it out more than 20 years ago, but I see no reason for believing that the same principles do not apply to wet plate. Judging by the questions that usually arise at lectures, I can only conclude that the majority of half-tone operators are still floundering, and have no very definite system of working, and that the wet-plate process has only survived because it lends itself so readily to the faking which has become a tradition in the trade. There is no theoretical reason why a dry-plate screen negative from any reasonable copy should not be perfect when it leaves the fixing bath.

In the early days of screen operating the phenomenon of diffraction attracted some attention, but it was apparently dismissed as of little importance. I have recently devoted a considerable amount of study to this branch of the subject, and I have come to the conclusion that diffraction plays a very important part in the formation of the half-tone dot and the gradation of the negative, and is, in fact, the crux of the question.

The amount of diffraction varies with the screen ruling, and is greater with fine than with coarse rulings. I have succeeded in measuring the diffraction sufficiently near to enable screen distances to be plotted so that negatives can be made from the same copy with 50-, 65-, 80-, 100-, 120-, 133-, 150-, 175- and 200-line screens, with the same stop, same exposure, and same development of the plate, and practically identical negatives are the result.

I should be glad to hear whether it is claimed that any other system can do this. E. A. BIERMAN, F.R.P.S.

FORTHCOMING EXHIBITIONS.

March 27 to April 8.—Dennistoun Amateur Photographic Association. Particulars from the Exhibition Secretary, Colin Graham, 448 Duke Street, Dennistoun, Glasgow.

March 28 to April 1.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 5 to 8.—Faversham Institute Photographic Society. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

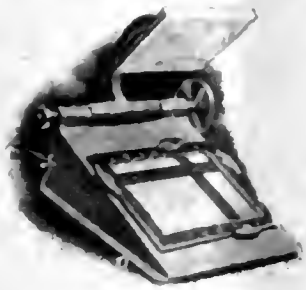
New Apparatus.

The Hodgson Printer. Made by The Hodgson Manufacturing Co., 2, Gerrard Place, Shaftesbury Avenue, London, W.1.

We welcome this new piece of apparatus, which is a machine of British design and construction, highly efficient for the rapid production of prints, and particularly for the printing of film-band negatives such as are handled in very large quantities during the summer season by those undertaking the supply of prints from

amateurs' negatives. We are particularly pleased to observe that in its design the machine strikes new ground. The user sits when working it; thus the comfort of the operator is consulted, and in this respect alone a greater output is obtainable in comparison with other printers, in the use of which an assistant becomes fatigued through performing long stretches of work whilst standing. Moreover, the machine leaves both hands entirely free for the manipulation of negatives and printing paper. As will be seen from the photograph, there are two foot pedals below the table. That on the right operates the electric lamps and pressure pad; that on the left raises the adjustable mask, which is a novel and essential part of the machine. Thus the worker has every opportunity for expeditious manipulation of the film negatives and for the feeding of the supply of printing paper.

The essential part of the machine is the printing bed and masking device shown on a somewhat larger scale in the second photograph. This is most solidly constructed of brass and aluminium, and is, in fact, an engineering piece of work which will last for years without getting out of order. Immediately above the glass bed of the machine is a metal frame, provided with a pair of sliding



metal masks, clearly shown in the illustration. These allow of masking from the smallest size up to the maximum size of negative accommodated by the machine, namely, half-plate. The construction automatically ensures that the masks are strictly at right angles wherever set, so that the printer obtains a perfectly rectangular picture on each piece of paper surrounded by a white margin. The edges of the frame which carry these masking strips are graduated so that the masks can immediately be set for any particular size of print of whatever shape. When in the down position the mask holds the negative firmly against the glass bed; for inserting a new negative or for shifting along a film negative band, pressure of the foot on the left-hand pedal slightly raises the mask, release of pressure fixing a fresh negative or the film-band in a new position.

The printing box is fitted with two 200 c.p. half-watt lamps, providing an average exposure of about one second on gaslight paper. Messrs. Hodgson have, however, provided a very ingenious movement, consisting in a switch by the operation of which the light from the lamps is dimmed so as to reduce the power and permit of convenient exposures from exceedingly thin negatives or when using bromide paper. The second switch, seen below in the first illustration, switches off all the lights from the machine. It is, of course, hardly necessary to say that the printing-box is fitted with an orange lamp, which is in circuit whilst the negative is being placed in position and the paper laid upon it, this orange lamp being automatically switched off when exposure is made by operation of the right-hand pedal.

We have nothing but praise for the design and construction of this machine, which is essentially a first-rate job, and embodies movements which are real savers of labour in this particular class of work. The outfit is mounted on a table of solid fumed and polished oak, and as shown, has the nests of shelves for the accommodation of negatives and unexposed and exposed printing papers. Without lamps the price of the machine is £14 14s. Lamps suitable to a customer's voltage are supplied at the prices of 7s. 6d. for each 200 c.p. half watt; 2s. 6d. for the orange pilot light.

The Apem Developing Tank. Made by Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1.

In issuing this developing tank the makers have adopted the very excellent and convenient plan of providing a hanger or carrier for each plate or flat film. The twelve hangers rest on a projection within the tank so that they hang free with a clearance of a short distance above the bottom of the tank. Thus, by passing the hand over the stout wire handles of the hangers, the batch of plates can be most easily given the movement which is necessary to overcome stagnation of the developer, with its accompanying occasional evils

of band markings on negatives. Moreover, any given negative can instantly be withdrawn from the tank and as quickly replaced, being held up for examination without the fingers ever touching the developing solution. The tank is provided with an outlet at the bottom, closed with a screw cap when the tank is in use for developing; by removing the cap the tank may thus be used for washing purposes with a current of water passing through it by standing it under the tap. The tank is of nickel plated copper (the carriers of brass) and is provided with a loop lid which effectively excludes light, although the apparatus is, of course, primarily intended for use in a dark-room. In postcard size, fitted with twelve carriers, the price is 26s. 6d.; in half plate size, 31s. 6d.

New Books.

EARLY BRITISH TRACKWAYS. Mr. Alfred Watkins, despite advancing years and health which of late has not been of the best, must always be finding fresh outlets for his intellectual activity. The present volume is an expansion of a lecture delivered last year before a Hereford Naturalists' field club, in which Mr. Watkins described many observations which he had made on the ancient trackways of Britain in time probably long before the Roman invasion. And from those observations he has formulated a theory which sheds an interesting light on the long bygone inhabitants of this island, and incidentally adds to our knowledge of ancient landmarks, place names and other matters of antiquarian investigation. Mr. Watkins shows that the ancient trackways were always straight, apparently because they were sighted between two extreme points and then marked, as regards the intermediate distance, in some cases by stones which still remain. He displays a great deal of ingenuity in deriving a great mass of evidence from the antiquarian remains and from the names of places in Herefordshire. The original nature of the book will be appreciated by the antiquarian. The volume is illustrated by a large number of reproductions of photographs and by two plates of maps showing some of the ancient trackways. It is published by The Watkins Meter Co., Hereford, and by Messrs. Simpkin, Marshall, London. Price, 4s. 6d. net.

PHOTOGRAPHIC AMUSEMENTS.—Mr. F. R. Fraprie's firm, the American Photographic Publishing Co., 428, Newbury Street, Boston, Mass., has republished, with additions, the volume, "Photographic Amusements," by the late Walter E. Woodbury, of which numerous editions appeared years ago. There are, no doubt, many who will derive entertainment in the making of trick photographs such as those of frankly bogus spirits, double-pose and distorted portraits, etc., but the subjects of some of the chapters in the book, *e.g.*, those on instantaneous photography, telephotography and night photography would now hardly be classified as more or less frivolous reliefs from the ordinary branches of the art. That they seemed so thirty or forty years ago is simply a sign of the great advances which photographic technique has made since that time.

A.B.C. GUIDE TO AUTOTYPE CARBON PRINTING.—This publication of the Autotype Co., 74, New Oxford Street, London, W.C.1, has run through many editions since its first issue in 1887. Although more ambitious text books of the carbon process have been written it still remains as explicit and reliable a guide to the working of the process as can be had or desired. The present edition contains a chapter on the modern Carbro development of carbon printing, in which the tissue is chemically exposed in contact with a bromide print. The price of the manual is 1s. 6d., 1s. 9d. post free.

WISDEN'S CRICKETERS' ALMANACK.—Messrs. John Wisden & Co. send us a copy of the fifty-ninth issue of their "Cricketers' Almanack," again a bulky volume of 676 pages, which contains a full record of play during 1921, and copious personal particulars of notable cricketers past and present. The price is 5s. 6d. net, post free.

THE £3,000 COMPETITION.—A Bulletin dealing with the many features of this all-British competition is being issued during the present season from the headquarters of the competition, 4, Oxford Street, London, W.1. Photographic dealers throughout the kingdom should make a note of the multifarious programme which is being carried out for bringing the competition prominently to the notice of amateur photographers. Beginning with next month a series of advertisements will appear in the general Press in all parts of the country. Blocks are obtainable free for dealers' own local advertising, and there are also posters and window bills, a full supply of which is immediately obtainable by any dealer. One reminder made in the Bulletin is that many film cameras, such as the "Carbine" and "Ensign," become eligible for taking part in the competition if fitted with a plate adapter, the prizes in the competition being for negatives taken on plates. A series of slides for attachment to dealers' correspondence is also obtainable from the competition headquarters.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, APRIL 3.

Forest Hill and Sydenham P.S. Print and Lantern Slide Competition.
Glasgow and W. of Scot. Amat. P.A. "Photographic Emulsions." A. Dowie.
Southampton Camera Club. "Some Pictures I Like, and Why." F. G. Ryder.
South London P.S. "Picture-Making at Home and in the Field." G. C. Weston.
Walthamstow P.S. "Colour Photography." E. Willcocks.

TUESDAY, APRIL 4.

R.P.S. "Imaginative Portraiture." H. Lambert, F.R.P.S.
Bournemouth C.C. "Through the Grecian Archipelago." Messrs. Butcher.
Cambridge Phot. Club. "The After-Treatment of the Negative." A. Dordan Pyke.
Exeter Camera Club. "Exposures." Dr. C. Beauchamp-Hall.
Hackney P.S. A Southdown Ramble. A. H. Page.
Rotherham Phot. Soc. Annual Meeting.
South Shields P.S. Free-Lance Talk on Picture-Making. E. A. Black.
Tyneside Phot. Soc. General Meeting.

WEDNESDAY, APRIL 5.

Croydon C.C. "Photography and Crime." G. H. Gardner.
Edinburgh P.S. "Photogravure Process." V. L. Alexander.
Ilford P.S. "Commercial Enlarging—With a New Method of Testing Exposure." N. K. Jackson.
Partick Camera Club. Flashlight-Night. John Roberts.
Rochdale Amateur P.S. "The Merits of Various Types of Cameras." H. and W. Bamford.

THURSDAY, APRIL 6.

Gateshead Camera Club. ——. G. Ternent.
Hammersmith Hampshire House P.S. "The Value of Failure." E. C. Perry
Letchworth C.C. "Photographic Apparatus." A Dordan Pyke.
Tunbridge Wells A.P.A. "Architecture." A. G. Wood.

SATURDAY, APRIL 8.

Hackney P.S. Outing to Greenwich.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday March 28, the President, Mr. W. L. F. Wastell, in the chair.

The chairman referred to the loss which the Society would sustain in the departure of Mr. Renwick, through the latter's leaving England. Mr. Renwick had taken a most active interest in the Society, and was particularly identified with the foundation and organisation of the Scientific and Technical Group. As that was perhaps the last occasion on which Mr. Renwick would be present, he expressed the good wishes of the members for his prosperity and happiness.

Mr. Arthur C. Banfield was unable to read his paper on the Trist three-colour camera, owing to the fact that the camera was unexpectedly not available. By way of a substitute, Mr. Banfield showed a new design of prism spectroscope of Messrs. Adam Hilger's. It was built in the form of a microscope, and was fitted with the Hilger attachment for indicating the Angstrom numbers of the lines.

Two papers dealing with the Osglim lamp were then read by Mr. Ryde, representing the General Electric Co., and Mr. B. V. Storr, of Messrs. Ilford, Ltd.

Mr. Ryde explained the principle of the lamp, viz., the luminescence of a rarefied mixture of a mixture of neon and helium gases under a given electrical pressure.

Mr. Storr described the results of some provisional tests on the use of the lamps in dark-room illumination. Although the light was chiefly red and yellow, there was a bright blue line in the spectrum, so that a pale yellow filter was needed in order to make the light safe for such sensitive materials as ordinarily could be developed in bright orange light. Even so, he found that the greater safety for equal brightness (or *vice versa*) could be obtained by the use of an ordinary metal-filament lamp.

Dr. Higson said he made the lamps safe by coating the bulbs with eosine-gelatine solution, which cut out the blue and violet. To cut out the yellow also, he added a coating of methyl violet.

Votes of thanks were accorded to the lecturers and demonstrators.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The meeting of the Council, adjourned from March 10, was held on March 24, at 35, Russell Square, when there were present:—

Messrs. Marcus Adams, Angus Basil, Arthur Bennett, Frank Brown, W. B. Chaplin, Gordon Chase, Alexander Corbett, C. F. Dickinson, Alfred Ellis, Reginald Haines, George Hana, Richard N. Speaight, H. C. Spink, H. A. St. George, and F. G. Wakefield, with Lang Sims, secretary.

Mr. Alfred Ellis took the chair.

The Secretary announced apologies for absence from the President (Mr. Swan Watson) and Messrs Chapman, Gray, Lambert and Turner.

The minutes of the previous meeting were taken as read.

Finance and Propaganda Committees.

Mr. Speaight said that Mr. Hana had placed before him certain figures relating to the proposed "Record," which had completely satisfied him as treasurer, and had satisfied also his colleagues on the Finance Committee. That being the case, in accordance with his promise on the last occasion, the new venture would have no more hearty supporter than himself. (Applause.) He proposed: "That the new publication should be issued monthly, and that the Propaganda Committee proceed."

Mr. Chase seconded, and this was agreed to unanimously.

Some discussion ensued on the preparation of literary matter for the "Record" and the appointment of an Editor. Mr. Hana detailed the inquiries which the Propaganda Committee had made on this subject, and it was understood that the Committee would at a later stage bring forward definite proposals.

Congress and Exhibition.

On the report of the Combined Congress Committee, which was brought forward at the previous meeting of the Council, Mr. Wakefield reported progress with regard to the arrangements for stands for trade exhibitors.

Mr. Speaight, Mr. Haines and others reported with regard to the particular arrangements of which they are in charge.

Message to American Congress.

Mr. Haines asked whether the message which the Council at the last meeting had decided should be sent to the American Congress meeting early in May had been dispatched.

The Secretary said that this had not yet been done, but that, as instructed, the Chairman, Treasurer and Secretary would draft an appropriate message to be sent in time.

Next Meeting of Council.

The Chairman drew attention to the fact that the date at which the next Council meeting would ordinarily fall was Good Friday. It was agreed that the meeting should take place on the Friday following—that is, April 21.

Correspondence.

The Secretary read letters from members in which questions of dispute as to charges or requests for information had been dealt with by him to their satisfaction. A letter was read from a Press Agency regarding the reproduction by two illustrated papers of separate pictures taken from a group, the work of a London photographer, with regard to which the newspapers claimed, so it was stated, that the one fee of 17s 6d. paid for the group should include the payment for all the separate pictures. On the proposition of Mr. Basil, seconded by Mr. Haines, it was agreed that the Secretary should ask for an interview with the art editors of these newspapers and ascertain whether the facts were as alleged by the Agency, and, if so, that the injustice of the procedure should be pointed out to them. The Chairman suggested that the photographer should also be seen on the subject. It was agreed to thank the Press Agency for bringing the matter to the Council's attention.

A letter was read from the Federation of Master Process Engravers urging that some means should be taken, if possible, of bringing about a reduction in the prices of photographic materials. It was agreed, on the proposition of Mr. St. George, to reply that if the Federation could suggest some means whereby such pressure could be brought, the Association would be glad to co-operate.

Appointment of Chairman.

Mr. Ellis said the next business was the appointment of chairman; he did not intend to seek re-election, and he had to thank the Council for the patience and courtesy extended to him during his twelve or thirteen years of office. (Applause.)

Mr. Speaight took the chair *pro tem.*

Mr. Frank Brown proposed a hearty vote of thanks to Mr. Ellis. He had never come across a more able or affable chairman; he hoped that Mr. Ellis would continue a member of the Council.

Mr. St. George seconded. The office had not been easy to fill, but Mr. Ellis had filled it to the general admiration.

The vote of thanks was carried unanimously and with applause.

Mr. Speaight proposed the election of Mr. Alexander Corbett to the chair, and this was seconded by Mr. St. George and carried unanimously, also with applause. Mr. Corbett then took the chair and said how much he appreciated the honour done to him.

Appointment of Secretary.

Mr. Lang Sims said that there had been a meeting of the Finance Committee, and he had been given a synopsis of what was agreed to with regard to the appointment of secretary. He thought the terms for the duties laid down under the new articles were adequate and generous. It was not his intention, however, to remain in office; he resigned at that meeting. His appointment was due actually to terminate that day, but if it was desired he would remain in office for one week longer. He was sorry that he could not say the kind things Mr. Ellis had said; he had a certain amount of regret at going, but he quite definitely resigned.

Mr. Speaight said that he was sorry for the resignation of Mr. Sims. No man on the Council was more valuable than the retiring Secretary; if his resignation was definite he wished to thank him personally and as treasurer for the help he had given. (Applause.)

Mr. Hana supported Mr. Speaight's remarks. There was no doubt as to Mr. Sim's great ability and prestige, and they only hoped his successor would do as well.

Mr. Sims thanked Mr. Speaight and Mr. Hana. He had done his best. The books of the Association were now in thorough order.

The Chairman hoped that Mr. Sims would still remain on the Council. Mr. Basil proposed that, under Article 40, Mr. Sims be co-opted a member of the Council on his retirement. Mr. Speaight seconded, and this was carried unanimously.

Mr. Sims thanked the members.

Mr. Hana proposed Mr. Alfred Ellis for the post of secretary. He could not conceive any man more capable of the office. Mr. Adams seconded, and Mr. Frank Brown, as a country member, warmly supported the nomination; on being put, it was unanimously carried. Mr. Ellis said that he accepted the office and agreed to the conditions laid down by the Finance Committee. He rejoiced to think that he was back in the post he occupied just about 21 years ago, and he promised that he would do his very best to start the new Association and help to make it even more successful than the old. (Applause.) He tendered his resignation as a member of the Council.

Other Business.

Other matters considered were a letter to be sent to Mr. Kaye, of Manchester, with regard to a proposed meeting of photographers in that city.

An informal discussion then ensued on the instance of Mr. St. George, with regard to the scales of minimum prices for commercial photography, which was adjourned to the Council meeting on April 21.

CROYDON CAMERA CLUB

"Novelties and home-made apparatus" were considered last week.

The president, Mr. John Keane, first showed the "Luxol" portable dark-room lamp, which burns ordinary paraffin oil held by absorbent material. Many members had employed it with satisfaction, and the safety of the ruby glass was vouched for by Mr. Hibbert, who had tested it.

Next came Griffiths' "Fortex" valve for adding many useful exposures, from ½ second to 3 seconds, to cheap shutters. Mr. Harpur, with a York fireman's long view of things, maintained the 3 seconds was far too short. Careful tests with stop watches proved the instrument to be correct. Specimen prints on cream "Noctona," a recent introduction of the same firm, followed, a

welcome variety of an excellent product. Cheers greeted the production of a large parcel of free samples with developer complete.

Mr. F. Ackroyd showed electric torches fitted with hand-operated miniature dynamos, and an excellent way of converting, by means of a file, old-pattern Gillette safety-razor holders into the latest improved model. How many patents this procedure infringes he did not mention.

Mr. E. A. Salt proudly exhibited a dust cap for bottles improvised out of half of a capped tube in which upright incandescent mantles are supplied. A slip of gummed paper holds the cap secure on the tube.

Mr. Vivian Jobling alleged that the full merit of this remarkable invention was due to him, and him only, which long-prior publication proved. He regarded Mr. Salt as a pirate of the worst description. The latter, in turn, said he felt saddened at the unblushing sacrifice of truth to envy, by one whom previously he had held in some respect.

Mr. B. J. Rose interrupted further compliments between the rival inventors by mentioning he had applied the revoluntary principles of "Intimate Photography" to pinholes. Among other examples he showed a portrait on a quarter-plate taken with a pinhole 1/50th inch in diameter, 2 inches from the plate, and 6 inches distant from the sitter's nose. In a conservatory, medium light, one minute was given on an Imperial S.R. plate. For texture, and emphasis of the near features, and abrupt recedence, the striking production crowded out Mr. C. P. Crowther from his own pet preserves.

Anyone who wishes to produce an exceedingly funny result has only to follow in Mr. Rose's steps, and might even go one better with a pinhole 1½ inch distant from the plate, and proportionally nearer the nasal organ of the sitter. Actual contact is to be avoided as unduly prolonging exposure. The amount of the victim included can be ascertained with a larger hole. Mr. Rose employs holes up to ¼ inch, dependent upon their distance from the plate.

Another tip of his was a cheap and good dead-black for woodwork—to wit, Bowman's solid ink stencil-black. It is sold in flat tins, and is best applied with a stencil brush.

Many ingenious contrivances were shown by Mr. Jobling, including efficient shutters and camera fittings, all requiring drawings for description. Later in the evening, when kindly attempting to explain "shutter efficiency" and "equivalent exposure" to a professional member, the latter suddenly remembered an immediate engagement elsewhere, and left with corrugated brow.

Mr. Handel Lucas brought an interesting evening to a close by introducing the subject of three-colour photography. Many years ago, listening to a lecture by a member, he had been much struck with its possibilities, and subsequently has discarded palette and brush for the art of the camera, which he held to be truer to Nature, a somewhat provocative dictum which was not taken up.

Many examples of a secret colour process with photographic basis worked out by him were passed round, and though apparently having no connection with three-colour work in any form, they were undeniably fine in all respects. Much insistence was laid on the necessity of a black key to coloured pictures, and ingenious arguments were advanced in support. Incidentally, it happens to be a necessity in the process evolved by him

Commercial & Legal Intelligence.

Legal Notices.—At an extraordinary general meeting of the members of the Premier Animated Photo Co., Ltd., held at 6, Quality Court, Chancery Lane, W.C., a resolution was passed to the effect that the company be wound up voluntarily, and that Mr. Arthur William Love, 61, High Street, Walton-on-Thames, Surrey, be appointed liquidator.

NEW COMPANIES.

Camera Craft, Ltd.—This private company was registered on March 20, with a capital of £1,500 in £1 shares. Objects: To take over the business of photographers and dealers in photographic supplies carried on by C. A. Hornby and E. J. Chard at 35, Queen's Avenue, N.21, as the "Camera Craft Service." The first directors are: C. A. Hornby, 88, Fernleigh Road, Winchmore Hill, N.21, photographer; E. J. Chard, 47, Old Park Road, Palmer's Green, N., photographer (both permanent, subject to holding £50 shares each). Remuneration as fixed by the company. Registered office: 1, Osbourne Road, Palmer's Green, N.13.

News and Notes.

Correction.—In the paragraph on page 165 of our issue of last week, March 24, an error occurred in specifying the components of the Ferguson copper toning bath. "Ferrocyanide" should, of course, have been "ferricyanide."

Mr. Percy J. Slater, Sawtry, Peterborough, sends us his latest price-list for enlarging and printing in bromide, the tariff representing substantial reductions of charges. Discounts allowed to bonâ-fide professional photographers may be obtained on application.

Nobel Industries, Ltd.—A booklet descriptive of the branches of manufacture in which this amalgamation of many firms is concerned has just been issued from the head offices, Nobel House, Buckingham Gate, London, S.W.1. Among the firms comprised in the Nobel Co. is Necol Industrial Collodions, Ltd., manufacturers of collodion and Necoloidine for photographic and microscopic work.

Brighton Beach Photography.—Brighton beach traders are apparently expecting a good summer, for when "pitches" were offered by auction last week the total realised £2,510 for 91 stalls; this compares with £1,122 for 83 stalls last year. There were 12 photographic pitches sold, they fetching a total of £390. Bournemouth stands were sold on the same day, the 30 realising £2,474, as against £775 last year, but the number of photographers and the prices paid were not stated.

Photographic Fair.—It is announced that a special concession will be made to professional photographers visiting the Photographic Fair, to be held at the Horticultural Hall, Westminster, from May 1 to 6, in the shape of the issue of a season ticket for the week at the nominal price of 1s. The ordinary single admission to the Fair is 1s. 6d. Professional photographers thus secure admission to the Fair at any time during the six days it remains open by applying beforehand to the Secretary of the Fair, Sicilian House, Southampton Row, London, W.C.1. This concession is made only to bonâ-fide professional or trade photographers, who should make application upon their ordinary note heading.

Raw Photographic Base Paper.—The announcement is made in the "Financier" of Wednesday last of a provisional agreement for a fusion of their interests between the two paper-making firms of Wiggins, Teape and Co. (1919), Ltd., and Alex. Pirie and Sons, Ltd. Both firms are of old and high standing in the paper trade, and both within the last few years have taken up the manufacture of raw photographic paper base. Messrs. Wiggins, Teape, a year or two ago, laid down a factory for this branch of their business at Woburn, Bucks., and Messrs. Pirie have done the same at Aberdeen, through the medium of Pirie's Photographic Paper Co., Ltd., the shares of which are largely held by the parent company.

The Scottish Federation.—The Blue Book for 1922-23, of the Scottish Photographic Federation, is once again a full and useful record of the activities of the Association, and of the help which it extends to photographic societies north of the Border. It contains a list of federated societies, of lecturers, demonstrators and experts whose services are available, and a score or more of pages briefly itemising the scenic attractions of places in Scotland, with particulars of dark-rooms and of members of the Federation, from whom further particulars can be had. The hon. secretary, Mr. James W. Mackenzie, 153, Hope Street, Glasgow, is always willing to give his help to photographers seeking a club or having the intention of establishing an Association.

Testing Paintings by Photography.—Photographic tests which enabled experts to tell genuine old masters from copies were described by Prof. A. P. Laurie at last week's lecture before the Royal Society of Arts. The first step in the examination of a picture, he said, was to go over the surface with a microscope to find possible repaintings and also to ascertain if the signature had been added at a date later than the painting. The pigments were next examined to decide the date of the picture. In some cases a tiny microscopic sample might have to be removed. The actual painter was discovered by means of enlarged photographs of typical pieces of brush work. Portions of pictures by the supposed painter, which were universally accepted, were in the first instance photographed and then enlarged, and afterwards carefully compared with similar ones of the picture under examination. These photographs were also compared again with the original pictures, and finally the prints were cut to pieces, and portions of the

brush work from undoubted pictures pasted on to suitable places on the prints of the picture to be identified, and these made-up prints again photographed. As an illustration of these methods (says the "Daily Chronicle" report) he showed photographs of the brush work of Watteau and of a copy, photographs of the Rokeby Venus, the Spanish Admiral, and the "silver" portrait of Philip. He pointed out how it had been possible to prove the date of the painting of the Rokeby Venus within some 30 years, and, also, that the Cupid was painted at the same time. A series of enlarged photographs of well-known Rembrandts and one or two of his followers were exhibited, and the professor demonstrated by means of this method that "The Good Samaritan" in the Wallace Collection was painted by Rembrandt.

KEEPING TO ONE SHUTTER-SPEED EXPOSURE.

To the Editors.

Gentlemen,—I learn from the Croydon Camera Club's report on page 176 of last week's issue of the "B.J." that the simple system of exposing advocated by Mr. W. Sanderson rather upset the equilibrium of some of Croydon's pundits. Their criticisms were no doubt due to the fact that the system has not been tested by them because of lack of facilities, the system not being quite so easy to work in the ever-changing English climate as it is under the sunny skies of Italy, where at times the light is remarkably constant in quality.

It has been my lot to make some hundreds of hand and stand camera exposures in Italy, and some thousands of exposures in lands nearer to the equator, and experience has taught me the value of the one shutter-speed of working. Mr. Sanderson's speed, it appears, was approximately 1/100th of a second, whereas my standard speed was 1/60th. When the subject was of such a character as to necessitate longer or shorter exposures, such alterations were brought about by the simple act of altering the size or value of the stop, the standard exposure of 1/60th being that most suitable for *f*/8, and for the ordinary plates I invariably used. I will not insult your intelligence by telling you exactly how I regulated exposures by the use of stops larger and smaller than *f*/8. All I want to do is to record my support of a system which I believe is too little known, or, at any rate, too little practised.

Even to-day, and here in England, I always keep the shutter of my Presaman reflex set at 1/30th of a second, and invariably use it at this speed, manipulating the stops to suit the light and the plate.

The system is of the utmost value, and there is much more in it than many imagine, and some day perhaps you or someone else will deal fully with the theoretical side of it. Expert workers like Mr. Sanderson know the practical side of it, as also do several less-experienced workers like myself, and the Croydonians would do well to sit up and take a bit of notice of what appears to them to be a new idea.—Yours truly,

I. T. Woods.

MEASURING FOCAL LENGTH OF LENS.

To the Editors.

Gentlemen,—In answer to Mr. W. E. Debenham's letter in your last issue. Both Mr. Jobling and I quite recognised that any special apparatus for measuring the focal length of a lens must have limited application, and little if any, to the professional photographer. Still, there are many amateurs who take a pride in constructing apparatus, and that described by us would be welcomed by members of photographic societies.

The accuracy of Clay's method was confirmed by tests with high-grade anastigmats engraved with their focal length, the readings of the home-made appliance exactly coinciding.

As suggested by Mr. Debenham, tests to check the accuracy of the method mentioned, and first published by him (who has done much useful work in the past in extending optical knowledge), certainly would be interesting. The exigencies of other affairs hardly permit me to undertake the job. Possibly some reader might do so, and publish results.

It, however, seems to me that the accuracy of any method of determining focal length dependent upon the measurement of scale images on the ground glass of the camera will turn on the personal equation of the operator; also, that measurements will be vitiated with lenses possessing distortion unless a very small angle be included, which adds to likelihood of error.

But, for all practical purposes, the simple plan proposed by Mr. Debenham will meet most requirements, especially those of the professional photgrapher, who in the studio is working with ever-varying camera extensions.

Such a method, of course, does not directly indicate the position of the node, but the table furnished some time ago by the Editor of the "B.J.," giving the position of the node in many types of lenses in common use, can be consulted. Unfortunately the figures given are in relation to lenses of varying foci, involving a little calculation for other focal lengths. The adoption of unit focal length would have been more convenient.—Yours faithfully,

E. A. Salt.

Sanderstead, March 24

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION OF GREAT BRITAIN AND IRELAND, LTD.

To the Editors.

Gentlemen,—Will you kindly allow me, through the medium of your paper, to make known to the members of the P.P.A. that Mr. Lang Sims having resigned the secretaryship of the Association, the council have appointed me to the post. All communications, therefore, for "The Professional Photographers' Association of Great Britain and Ireland, Ltd.," should now be addressed to me at the address below.—Yours faithfully,

Alfred Ellis,
Secretary.

2, Vinery Villas, Hanover Gate, N.W.8.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; Recent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. A.—Particulars of the lamp to which you refer can be obtained from Mr. D. Charles, 50, Webb's Road, Clapham Junction, London, S.W.11.

R. B.—The statuettes to which you refer are made (under the name of "Panel-Photettes") by Mr. A. Smith, 107, Melbourne Grove, East Dulwich, London, S.E.22.

F. H.—The process for red tones is to sepia tone by the usual method of bleaching with ferricyanide and bromide and treating with sulphide, and then to tone the washed prints in an ordinary gold sulphocyanide bath, as used for the toning of P.O.P.

J. S.—For large heads where the distance between the camera and the sitter is comparatively small, there is a material advantage in the use of a 20-inch lens over a 16-inch, and still more over a 12-inch, but for full lengths, or even half lengths, in cabinet size there is no substantial advantage in using a longer focus lens than 12 inches.

W. F.—The orthodox material for belts in print dryers is a fine surface white duck. Of the materials you mention, not only are the surfaces unsuitable, but they would not keep their shape

for any length of time. Whatever material you choose must be pure linen as cotton or wool would not absorb the moisture quickly enough.

R. R.—For copying blue prints so as to get good contrast between the blue ground and white lines you want to use a filter, such as the Wratten A or F, in conjunction with a process panchromatic plate. You can buy the filters in film form fairly cheaply. Prices and information from the Wratten Division of Messrs. Kodak, Ltd., Kingsway, London, W.C.2.

W. K.—You do not need to do anything to secure the copyright in your views. The mere fact that you have taken them "on your own" creates the copyright as your property. There is nothing in copyright law nor in common law to prevent you taking views from such standpoints that your prints will be substantially the same as those taken by other people.

R. C.—There is little doubt but that your trouble is caused by bad fitting or the focussing adjustment which allows the back to run in slightly when the slide is inserted or moved. If it is a rack adjustment, lift the rack and put one or two strips of brown paper under it. If a screw, you will probably want a new brass nut. Many cameras are fitted with a clamping screw to prevent slipping in this way.

W. J.—So far as anyone preventing you from making or marketing the printer which you describe, that is solely a question of whether the device which you use has been patented. It would probably take a long time to examine the patent specifications which have been published, but it would be quite easy for you to do it with the assistance of the librarians in the Patent Office Library, which is open free to the public, at 25, Southampton Buildings, Chancery Lane, W.C.2.

W. A.—For formulæ and instructions in making emulsions you want one of the old editions (about 1880 to 1890) of Abney's "Instruction in Photography" or Abney's "Photography with Emulsions," both of which are long out of print, but obtainable from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2. These manuals describe the making of a comparatively slow emulsion. There are no published particulars for the manufacture of the modern high-speed emulsions.

L. B.—The question you place before us is clearly one which can only be dealt with by a solicitor who is in possession of all the essential facts relating to a business. If the concern is a limited company you can, of course, buy as many shares as any present holder may care to sell you. You will then share the profits pro rata. We cannot see what benefit will accrue to the present owner of the business by taking a partner, unless the partner does the work of the manager, who would then be dispensed with.

R. M.—An excellent general book on composition in landscape and portraiture is "The Appeal of the Picture," by F. C. Tilney, published by Messrs. Dent and Sons, Ltd., 10-13, Bedford Street, Strand, London, W.C.2. Other books are "Picture Making by Photography" and "Pictorial Effect in Photography," by H. P. Robinson, and "Practical Pictorial Photography," by A. H. Hinton. Prices from about 1s. 6d. to 3s., from Iliffe and Sons, Ltd., 20, Tudor Street, London, E.C.4. If out of print, you could get them from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2.

W. T.—There are few varnishes which will stand both acids and alkalies. One made of gas tar and naphtha (the ordinary burning variety) mixed in equal parts immediately before use, has been found to answer well, as does one composed of asphaltum, 4 ozs.; pure rubber, 30 grs.; mineral naphtha, 10 ozs. Give three coats with a stiff brush, drying after each. The rubber is to keep the asphaltum from chipping. Asphaltum is a fairly pure form of asphalt or bitumen. It is not usual to waterproof teak tanks or dishes, as, if well made, they are usually more watertight without.

M. E.—There is nothing for your purpose whiter than white distemper, but you must have a full light upon it, as white in shadow comes out grey. We recommend you to procure "Sketch Portraiture," by J. Spencer Adamson, issued by our publishers, price 1s. 3d. post free, which deals fully with the subject of white backgrounds. There is, so far as we know, no directory devoted to photographers. Kelly's directories for the various districts include them, as does also the same firm's "Directory of the Chemical Industries." Address: Kelly's Directories, Ltd., 186, Strand, London, W.C.2.

N. J.—A formula for combined developer and fixer is as follows:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs,
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

G. T.—For the literature of making relief prints we may perhaps refer you to an article by E. J. Wall in the "Colour Photography" Supplement to the "British Journal" of August 5 and September 2, 1921. This refers particularly to the use of peroxide in making reliefs. These reliefs are, of course, exceedingly shallow, and there is, in fact, no very practical process of making really considerable reliefs. The best method for this purpose consists in the use of a thick gelatine film sensitised with bichromate as employed in the Woodbury process, but the method is by no means easy to work. For information concerning it there is no better book than "Photographic and Photo-Mechanical Printing Processes," by W. K. Burton, now out of print, but obtainable from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2.

W. G.—Your room is hardly suitable for full lengths, partly on account of the absence of a sufficiently high side light (your highest point being only 6 ft. 5 ins. from the floor), and partly because of the short working distance, which would only be 9 ft. between lens and sitter; this is allowing 2 ft. for the sitter and 3 ft. for the camera and operator. This would only allow you to use a lens of 6½-ins. focus, which might do for cheap work, but certainly not give good perspective. You would require at least an 8½-in. lens for heads and three-quarter lengths. If you could fit a couple of 1,000-c.p. half-watt lamps fixed close to the ceiling to give top light you could manage the lighting for full lengths; without them you should only attempt sitting figures. A reflector is easily made of a light frame, about 6 ft. by 2 ft. 6 ins., covered with white calico with a couple of hinged struts behind. Lace curtains would hardly be satisfactory; plain white muslin or nainsook would be better. Any of the developers mentioned would answer for portraits, they should, however, be more dilute than for outdoor work. It is not so easy to get good vignettes on bromide paper, as you are using a more concentrated light than daylight. You must have a good distance between the vignette card and negative, say, 2 ins., the opening in the card should be covered with very thin tracing paper or ground glass, and the light should be diffused by a ground glass screen close to the lamp. Plate glass treated with dilute ox-gall will give the best gloss, but ferrotype plates answer very well, and only require an occasional polish with the merest trace of ordinary petroleum.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3231. Vol. LXIX. FRIDAY, APRIL 7, 1922. Price Fourpence.

Contents.

SUMMARY.

In consequence of the Easter holidays the "B.J." will be published a day earlier next week, and, therefore, line advertisements for insertion in next week's issue (April 14) must reach our publishers not later than 12 (noon) on Tuesday next, April 11.

M. L. P. Clerc has worked out formulæ and a table for the conversion of plate speed numbers according to the five systems in current use in this country and on the Continent. (P. 200.)

Mr. A. Lockett describes a simply made appliance for the measurement of effective diaphragm aperture of lenses. (P. 199.)

At the Royal Photographic Society, 35, Russell Square, there is now being shown a remarkably fine collection of photographic portraits by Dr. Henry B. Goodwin, of Stockholm, who, at next Tuesday's meeting of the Society, will lecture on "Photographic Portraiture Pure and Simple." (P. 201.)

On page 198 we refer to the shortcomings of much modern portrait work and point out the way to attaining a higher level.

Some notes on finding models for head and shoulder studies are contributed by a correspondent. (P. 200.)

The business to be done in making semi-transparent prints for use as window advertisements is emphasised on page 198, where some hints are given on the method of their production.

Prices paid for photographic pitches on the Bournemouth foreshore will be found on page 205.

A correspondent states his experience of the relatively rapid fading of platinum toned bromide prints. (P. 207.)

The use of a plain glass flat filter when using similar light-filter flats in the camera is the subject of a paragraph on page 197.

Mr. E. J. Wall returns to the discussion of priority in inventions in colour photography. (P. 206.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT

Mr. E. J. Wall contributes an historical review of the origin and early development of the Photochromoscope. (P. 13.)

It is announced that a comprehensive treatise on colour photography by Mr. E. J. Wall is in the press in the United States. (P. 16.)

Details of the Triadochrome process of making three-colour prints, worked out by Mr. J. F. Shepherd, of which a short account appeared a month or two ago, will be found on page 15.

A recent patent specification, granted to Miss Florence M. Warner, formerly associated with the Warner-Powrie process, describes a system of screen-plate colour photography, according to which an emulsion coated screen plate is developed to a négative in complementary colours and from it is printed (on a panchromatic plate) a positive transparency, which is then bound up in register with a mosaic colour screen. (P. 14.)

EX CATHEDRA.

A Colourless Light-filter. Photographers and process-engravers who handle any quantity of colour work now and again come up against a problem which would not exist were a plain glass of the same thickness as the coloured filters recognised as an essential item of a set of "flats." One is sometimes called upon to make a pair of negatives, for instance, for a two-colour job, one of which must be made through a filter, while the other is best made on an "ordinary" or even a process plate. Or it may be that a line negative is required to register correctly with a colour set. If the process plate is made without a filter it is practically certain to be out of register, unless gelatine filters have been employed for the panchromatics. Sometimes, also, when the original is of a heavy character, or when the light is not of the brightest, focussing with a tricolour filter is anything but an easy matter, even to the keenest sight, and here again the plain glass will permit focussing to be done under the best possible conditions, with the certainty of obtaining sharpness without having to stop down further than is absolutely essential. Those who are familiar with the lengthy exposures sometimes called for in colour work will appreciate the advantage of the last point.

* * *

Current at Power Rate. The letter from Messrs. Wykeham Studios, Ltd., which appears on another page, raises a question of great importance to every portrait photographer, namely, the supply of current which is used in a photographic establishment for purposes other than those of ordinary illumination—the supply of such current at power rate. It will be seen that Messrs. Wykeham's Studios are resisting the imposition of a charge considerably below that for ordinary lighting, yet considerably above that which is commonly charged for "power." In so far as the legal dispute may relate to particular matters applying only to them and to their electrical suppliers, it would not be proper, we think, for us to comment upon it. But inasmuch as their resistance is designed to create a test case in which the question of the rate at which current for photographers' portrait and printing lamps and for other electrical appliances used by them in the production of photographs, shall be explored, there appears to be justification for drawing attention to the impending proceedings and for asking, on behalf of Messrs. Wykeham Studios, the support of photographers generally. That support may be given either in the shape of information as to "power" rates charged by other electrical undertakings for such purposes as we have mentioned, or of financial contributions to the costs of an action which, if decided in the favour of the photographers, may be of far reaching benefit to studios throughout the country.

Transparency Prints. In a recent issue of "Studio Light" attention is directed to the real opportunities for additional business on the part of a studio in the supply of semi-transparent prints for exhibition, in shop windows and other places, by transmitted light. In the daytime, under the ordinary illumination, the prints have the appearance of an ordinary photograph. It is found that the best means of rendering the prints semi-transparent is the somewhat heavy white mineral oil (liquid paraffin) commonly sold for medicinal purposes. The method of applying the oil is to brush over the back of the print with it and allow to stand for one hour. The process is then repeated, the print left to itself over night and excess of oil removed with a cloth the next morning. No advantage is gained by applying oil to the gelatine side of the print. With most papers the graininess of the paper itself is not exaggerated by treatment with the oil, providing the paper is dry; dampness is a cause of graininess. As a rule, full exposure and development require to be observed in order to obtain a print with ample deposit of silver in the shadows. Should it be required to attach the oiled print to glass, a suitable adhesive is made by swelling 125 grs. of gelatine in water, pouring off the surplus water, heating until the gelatine melts, adding 30 grs. of sugar, and making up to 3½ ozs. with water. Both the print and the glass are coated with the hot adhesive and squeegeed into contact.

PRESENT-DAY TECHNICAL QUALITY.

A COMPARISON between the quality, from a technical point of view, of the average of current portrait work and that of twenty-five years back appears to indicate that while there has been great progress in the artistic quality there has been an almost corresponding deterioration in the actual technique, as shown in the prints. This is the more surprising, as the makers of plates and paper have done everything possible to make the production of good work as simple as possible, although it is, perhaps, this very fact which has been the primary cause. In the earlier days, when the photographer had to prepare his own plates and usually to sensitise his paper, a long and painful novitiate had to be passed before even a passable result could be obtained, but the ease with which photographs can now be produced seems to have engendered a disinclination to take even a moderate amount of pains to get good results and to expect the manufacturers to supply materials which will make up for any amount of ignorance and carelessness in the studio and workroom.

Photography differs from most other arts and crafts, inasmuch as few of its practitioners have received any systematic training or have served any sort of apprenticeship. A natural taste for the work, with perhaps a little success as an amateur, is often deemed sufficient as a preliminary to taking the plunge into professional portraiture, so that it is hardly surprising that excellent apparatus and materials are not used to the greatest advantage.

It may be of interest to examine the various weak points of many workers categorically, and a start may be made with focussing, which is often faulty. As a rule the tendency is now to use a much larger lens aperture than was the case formerly, so that the greatest care is necessary to define the points of interest in the subject. We have noted in work bearing well-known names such laches as unsharp eyes while the hair and clothing are in focus; or shapeless hands due to neglect of the swing-back or diaphragm. Such negatives which would once have been ruthlessly destroyed are now tolerated, with a resulting loss of reputation which is not always realised by the operator.

Correct exposure is not such a matter of course as it should be. To our knowledge many otherwise clever operators fail in this direction, either from sheer forgetfulness or from a natural inability to perceive variations in the light. This is a serious fault which needs careful study to overcome, but one whose elimination will remove three-fourths of the difficulties in producing good work. With correct exposure, development becomes a simple task, and the necessity for a number of special printing papers to compensate for bad negatives is almost entirely eliminated. Our predecessors had the advantage of us in this respect; if a wet collodion negative was unsatisfactory, another was taken immediately. For bad negatives were useless for albumen prints; now they are cherished and coaxed with "vigorous" or "normal" or "soft" papers into giving a result of some sort.

Printing is not studied as it should be. The tendency is to give a full exposure to bromide papers and to trust to short development to give the desired result. This is a lazy way of working, which results in poor, rusty-black prints, and sickly yellow-toned ones. Negatives should be carefully classified according to densities, and a correct exposure given, that is to say, one which allows of full development. Incorrect exposure falsifies the scale of tones as it exists in the negative and is unjust to the operator.

There is a mischievous doctrine that certain classes of negative are required for different printing processes, and this has been the cause of much poor work. Because a passable print can be obtained from a thin negative upon bromide paper it does not follow that thin negatives give the best results in this medium, nor that because a rather hard negative will yield a good carbon that all negatives for carbon printing should be hard. What may be called a good negative is one which can be printed successfully by any process, and a good test for this is a printing-out paper, either collodion or gelatine, which does not allow of "faking" in exposure or development.

Economy is laudable, but it is not economy to send out inferior prints, if it be felt that better prints could possibly be produced. It was once a general custom for the proprietor of a studio to go through each day's prints and to destroy such as he thought unworthy of his reputation, and it would be well if this custom were still observed. Even in a single-handed studio the owner should be a severe critic of his own work, and not be content that it will be accepted without protest by the customer. If prints are only just good enough to pass muster, they are certainly not good enough to serve as an efficient advertisement of his work, and it should always be kept in mind that every print sent out is a potential advertisement for a business.

Our criticisms are not directed at any particular grade of work, as they apply to all. The budding artist who opens in the West End must not think that his artistic capabilities will atone for careless manipulation, and the most modest postcard worker will find his reward in doing better work than his rivals. To the latter class we would especially point out that his customers appreciate technique rather than art, and that a well-focussed, properly-exposed portrait will score every time. Once a proper method of working is attained, it costs no more trouble to make good photographs than it is to make poor ones, and the financial results of good work should be a stimulant to take the necessary steps to produce them.

AN EFFECTIVE APERTURE METER.

The importance of a correct valuation of effective aperture when estimating exposure will no doubt be sufficient excuse for describing a handy apertometer devised, and found very useful, by the writer.

It is believed to possess the following advantages over previous appliances: that nothing requires to be fixed or held on the lens, centring is unnecessary, the eye does not need to be shifted between the two sightings, and measuring is dispensed with, the readings being shown automatically on a scale. In addition, the eye is directed horizontally, instead of having to be pointed downwards, which latter is found difficult by many people.

The distinctive feature of the apparatus is a right-angle prism (fig. 1), having a fine black line ruled across the middle

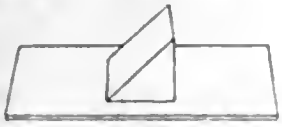

Fig. 2.

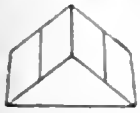

Fig. 1.

of both its 1-in. square faces. The long or hypotenuse side must not be silvered, neither should any part be covered. To receive the prism a panel is cut 4 in. by 1¼ in., and in the centre is made an aperture 1 in. square. The prism is glued in the opening as shown in fig. 2, one square side being flush with the bottom of the panel.

A stage is next needed, 5 in. by 2½ in., as shown at A in fig. 3. In it, ¼ in. from one side, is cut an aperture B, 2¼ in. by 11/16 in. At either side of the stage are glued grooved rails C and D, ¼ in. wide, for the prism panel to slide in.

Next there is wanted a millimetre scale E, 5/16 in. wide, to include 6 c.m. of graduations. This may be drawn very carefully by hand on smooth white paper, though a printed scale would be better if available. Note that the figures must be reversed, as shown in the illustration, since they will be viewed by reflection. The scale is glued by the side of the opening B.

The grooved stage needs to be mounted on a support, as seen in the perspective view of the complete apparatus (fig. 4).

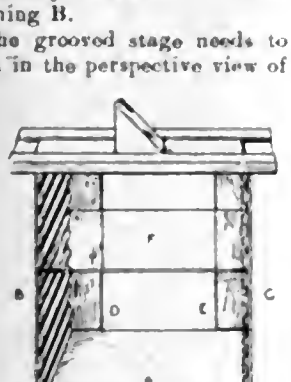

Fig. 4.

Fig. 5.

This consists of a base A covered inside with white paper to reflect light through the lens, two slightly tapering sides B and C, and a couple of narrow strengthening pieces D and E. The sides are covered inside with corrugated cardboard, to receive a piece of plain glass F which holds the lens, and to permit its adjustment to any desired height. The sides are 4½ in. high, 3 in. wide at the bottom, and 2½ in. wide at the top. The base is 3¾ in. by 3 in., while the strengthening pieces are 1 in. wide. Fig. 5 is a side elevation. The writer's apparatus is made entirely of stout strawboard, fixed with glue and bound at the edges with strips of brown paper, but thin wood would certainly be preferable.

To use the apparatus it is stood on a box so as to bring the prism level with the observer's eye. The piece of glass is adjusted to such a height as will bring the lens near the opening in the top, and the lens is stood upright on the glass. On looking in the prism two horizontal lines will be seen, as well as the reflected image of a portion of the scale. The observer has now to adjust his eye until the two lines coincide, so that one alone is visible. This is very easy, since they appear only about ½ in. distant. The prism panel is then gently pushed to or fro till the line just touches the upper edge of the diaphragm opening, as seen in Fig. 6, and the reading is noted where the line lies across the scale. In the illustration the reading is 32 mm. It is then only necessary to push the prism panel gently along, taking care not to shake the apparatus and thereby perhaps shift the lens, till the line just touches the lower edge of the diaphragm opening. While this is being done the lens and the scale appear to move upwards in the prism, in a direction perpendicular to the sighting line. The second reading is now noted, and on subtracting the first reading from it the remainder is the diameter

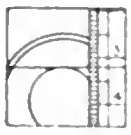

Fig. 6

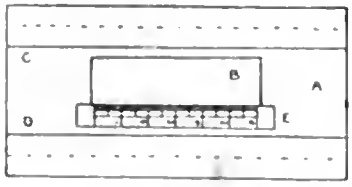

Fig. 3.

of the effective aperture. Thus, suppose the second reading to be 48 mm., the effective aperture is 48−32=16 mm. in diameter. By dividing this into the focal length the // number is obtained.

In some cases it is practicable to get the top edge of the diaphragm to coincide with zero on the scale, when the second reading obviously gives the effective aperture without calculation.

The apparatus will accommodate lenses with hoods up to 2½ in. in diameter, and of a length up to 3 in., but, of course, it can be made to any desired size, and with a longer scale. Although some may like to use a larger prism, it should be pointed out that there is no necessity whatever for the whole aperture to be visible. To simplify the diagrams only millimetre divisions are shown, but half-millimetre divisions are preferable. It is then quite easy to take readings accurately to within 0·25 mm.

Reference is made below to useful articles dealing with the subject, the first especially containing a valuable summary of essential facts and figures not to be found elsewhere in a form so comprehensive, yet comprehensible.

A. Lockett.

Bibliography. "The Speed of a Lens," by George E. Brown ("B.J.," 1921, pp. 550 and 580). "An Instrument for Direct and Rapid Measurement of F. Number," by C. Welborne Piper ("B.J.," 1917, p. 272); and Lecture at Croydon Camera Club. "Some Factors Concerning the Rapidity of a Lens," by Vivian Jobling and E. A. Salt ("B.J.," 1922, pp. 93 and 108).

A Musical Evening with Dancing was held on March 29 by the staff of Messrs. Griffin's, Kingsway, at which some 120 members and their friends congregated. Every one of the 24 items on the excellently arranged programme was thoroughly enjoyed, and much merriment was made over the "Fortex One-Step." A "Nectona Fox Trot," carried out as it was under suitable lighting conditions, proved a delightful experience. Credit for the success of the evening must be given to the organising committee, Messrs. A. Blackburn, W. Colls, H. Lindsay, and the Misses M. Neve and M. Purkiss.

PLATE SPEED NUMBERS.

In a recent number of *La Revue Française de Photographie*, M. L. P. Clerc has sought to perform the useful yet very difficult task of expressing the relations which exist between the different systems of rating the speeds of dry-plates. He does not minimise the difficulty of finding formulæ which, for example, will tell one what is the Watkins number corresponding with a rating of the plate according to Hurter & Driffield, or the German Scheiner, or Austrian Eder-Hecht systems. Nevertheless, he has worked out a series of formulæ and a table which provides at any rate an approximate comparison between the five systems of rating plates for speed which are currently employed. It is to be remarked that the German and Austrian systems are based on the measure of the smallest quantity of light which produces an image on the emulsion after development under certain prescribed conditions; whilst the English systems are based on the determination of the quantities of light yielding opacities in proportion to the illumination. Thus the former systems correspond with the region of under-exposure and are therefore sometimes termed "threshold" values, whilst the latter are representative of the period of correct exposure. Thus, strictly speaking, it is not possible to establish an accurate equivalence of the two systems, but only to determine empirically from numerous comparisons the average which corresponds to these different types of measure. Formulæ for expressing the measures, according to one system, in terms of each other, is, however, much less difficult.

If, for example, the symbols a, b and c be chosen to represent respectively the speed numbers according to H. & D., Watkins and Wynne, the formulæ expressing these values in terms of each other will be as follows:—

$$a = 0.68\,b \qquad b = 1.47\,a$$
$$a = c^2/60 \qquad c = 7.75\,\sqrt{a}$$
$$b = c^2/41 \qquad c = 6.4\,\sqrt{b}$$

If, on the other hand, we represent by d and e the numbers applying to the same emulsion according to the Scheiner and Eder-Hecht systems, the formulæ for conversion of these latter from one to another will be

$$d = 0.4\,e - 16 \qquad e = 2.5d + 40$$

By representing by the numbers 1 to 100 the relative degrees of sensitiveness of emulsions corresponding with degrees Scheiner from 1 to 20 the relative sensitiveness of an emulsion rated according to any one of the five systems may be computed by the following formulæ:

$$S = 0.139a \qquad S = 0.094b \qquad S = c^2/435$$
$$S = 1.275^{d-1} \qquad S = 1.1^{\,e}/62$$

These formulæ are much too complicated for practical use, and therefore M. Clerc has drawn up a table showing the comparative value of speed numbers according to the different systems.

Degrees Scheiner.	Degrees Eder-Hecht.	Hurter & Driffield (H. & D.)	Watkins.	Wynne.	Relative speed S.
1	42	7	11	21	1
2	46	9	13	24	1.27
3	48	12	17	27	1.62
4	50	15	22	30	2.07
5	53	19	28	34	2.64
6	56	24	36	38	3.36
7	58	31	45	43	4.28
8	61	40	58	49	5.45
9	64	50	74	55	6.95
10	66	64	94	63	8.86
11	68	82	122	71	11.3
12	71	104	153	79	14.4
13	74	133	196	90	18.3
14	77	170	250	101	23.4
15	80	216	317	114	29.8
16	82	276	405	129	37.9
17	84	351	515	145	48.3
18	86	448	660	165	61.6
19	88	570	840	186	78.5
20	90	727	1065	209	100

It is to be noted that the speed numbers according to the Wynne system differ so slightly from those used in the Cannevel or Michelin exposure meters that for practical purposes they may be considered identical.

THE PROBLEM OF THE MODEL.

THE passing of the Royal Academy's Sending-in-Day during the latter part of the month of March means a greater freedom (freedom sounds better than unemployment) for the orthodox artists' model, and advertisements offering her services to photographers may be expected in the Press.

The status of the model has improved wonderfully during recent years, and few people look askance when her calling is spoken of to-day. Twenty years ago, however, things were different. A generation ago none but the art journals—and they but rarely—would accept an advertisement of or for a model, but to-day the model finds a place for her announcements not only in the general Press, but even in the columns of the more austere and matter-of-fact "B.J."!

It is often stated in art circles that no good model need advertise, and that no good model can be secured through an advertisement; the subject is one of great controversy. The best, most serviceable and profitable model I ever had was obtained by answering her advertisement in a London evening newspaper, while the worst and most unprofitable one was secured in precisely the same way. The former was a "peach," and once figured largely on showcards and in lens catalogues, while the latter model—the unprofitable one—drew from me fees for a series of six sittings before I could expose a plate, and was never seen by me again. There are models and models.

Many photographers seek their models in Thespian realms, and after pantomime time keep a sharp look-out for those girls who, thanks to King Pantomime, have tasted of the delights of theatrical life and then take a long "rest," most of the younger models getting their first—and often their last—experience of the boards in a pantomime. But I have never been successful with models from stageland. The late H. P. Robinson tried them and found them wanting, as many others since his time have done.

Other photographers there are who have been known to wander alone or with an artist friend in Bohemia—or what is thought to be Bohemia—in search of models, but with little or no success. The cafés and like places within the quarter-mile radius of Piccadilly Circus teem with slouch-hatted, big-tied, unshaven young men who cannot paint but will, or who can paint but won't, and around may be found damsels, bobbed, deadly pale, and with slit-like eyes, but they are not models for the photographer. They might have served as such earlier in life before they themselves started painting and decorating, but in their present condition they are best left to the young painters whose canvases are not so cruel to Nature—or what is made to pass as such—as the photographer's lens and plate. Neither the land of theatres nor cafés and restaurants where artists most do congregate supply the ideal model for the camera.

To-day, I live near one of the largest jam factories, also one of the largest laundries, in London, and were I in need of a good photographic model to-day it would be among the crowd of workers in the two establishments that I would look for her, and, what is more, find her. I refer, of course, to the head or face, and not figure models; the latter are of a class by themselves, and I do not propose to deal with them in the present note. But this much may be said; if the artist's oft-quoted axiom, "The uglier the face the more perfect the figure," be true, it would not be among the factory girls that I would find a good supply of figure models. Rather would I extend by researches in the direction of London's policewomen, for among them I fancy an ideal figure could be found.

But supposing we have the opportunity of photographing a good professional camera model? What of it? Great care and caution are to be exercised. If a girl poses for several photographers, as she will do if alive to her business, you must be prepared to find that her face is rather common, and the better known her face is to the public the less value will your pictures of her be. You cannot, of course, expect her to sit to you alone, unless you pay her an exorbitant fee, and it would hardly be profitable for you to do so. I have in my possession to-day a large number of negatives of a once-beautiful model that have never been printed, and they will remain unprinted for some time, for after leaving my studio she visited a rival firm who flooded the market with her pictures before I could do so. This is one of the drawbacks of engaging and making studies of a well-known professional model, one to be prepared for, and, if possible, guarded against. The

obvious remedy against "dead stock" is to get your results in your window and showcases, or to lens, plate, and paper makers as required, at the earliest moment. Even hours are of account, for if a model gives you a sitting in the morning, she may be booked to attend a rival establishment in the afternoon.

Happily for the photographer the average model is a good conversationalist, and if you express doubts as to her qualifications she will very soon give you a list of photographers who have employed her. Her eagerness to support her claims is really her undoing, for the greater the number of her temporary employers the less likely are studies of her to be of any real value to you. It is the model who has sat to artists of the brush, but to few or no photographers, that is likely to be the most profitable and serviceable. Here and there may be found a good model as close as the proverbial oyster in the matter of talking; the majority, however, will not only boast of the many sittings given to photographers, but will suggest and take up poses given them by other camera men. When a model is so unwise and short-sighted to do this, you can rest assured that any "original" poses you think out will be described and demonstrated in detail to another worker later on.

Exhibitions.

DR. HENRY B. GOODWIN'S PORTRAITS

The Royal Photographic Society has opened an exhibition of portraiture by Dr. Goodwin, of Stockholm. His work, however, is quite well-known in England, for he is an energetic supporter of the London Salon. To judge of his capability by the occasional works he sends to Pall Mall is, nevertheless, to fail to get anything like a true view. It is a case where the *ex pede Herculem*, principle will not work. You can't judge of this Hercules by his foot.

The complete man as displayed at Russell Square is a man of considerable psychological power and ample versatility. His men and women are strong in personality, and whether he gives you a dancer or a mathematician he makes you interested in the sitter for the sitter's sake. This does not imply that his work is richer in content than it is fine in form. By no means. Dr. Goodwin is obviously as often struck and inspired by the aesthetic suggestions of a subject as by the human interest in its sitter. No. 48, for example, "Gala Fair Dancer," is a composition in an oval of which the lines of the arms and legs of the seated figure are as they are for design's sake. Again, the magnificent sweep of the lines in No. 50, a fine head and bust, are of more importance than the mere portraiture of another dancer, "Jenny Hasselqvist." With a keen sense of style Dr. Goodwin shows four portraits of this lady all utterly different in conception. No. 51 is not in a dramatic, but a quiet mood, and the treatment here takes the cue from the regular oval of the face, for all the lines have the clean, smooth compactness of the elliptical curve. Many figure studies are arranged with severe symmetry.

Perhaps the most remarkable efforts pictorially are a set of studies of a damsel who possesses hair having the quality of hanging together in curly strands. This figure, taken at half length or less, and usually nude, has produced a series of designs that remind one of the flat and archaic paintings of the early Renaissance; and Dr. Goodwin's lighting and treatment heighten the similarity. No. 62, with its flatness and edginess, and the long, curly locks, might be taken for a photograph of a Botticelli. Yet Dr. Goodwin assures me that no such idea or any attempt at archaism has ever entered his head. This shows how unsafe it is for people to accuse photographers of imitating paintings. The imitation arises unaided and unsought for, in most cases. Strangely enough, Nos. 60 and 61 of this series are very modern in feeling.

Another characteristic of this exhibition is a statuesqueness in several portraits of ladies with bare arms. It is rare to find so many classically beautiful arms in one show; they are so full and round that they look like those of marble statues. In No. 55, "Mrs. Karl Asplund," Dr. Goodwin has adopted a grey smoothness of treatment that even in the drapery gives a classic association of ideas. It is, to my mind, a fitting and very pleasing style for a pose so beautifully simple and of such real Greek spirit. The visitor will find other statuesque effects.

But the clothed and everyday sitter fares just as fortunately in Dr. Goodwin's hands. "Ira B. Goodwin" (40) is a splendid example of his rich, dark manner. "His Excellency Count Herman Wrangel" (5) is another excellent work, full of careful artistry, well planned, and with a tonal scheme like an old master.

The exhibition closes on Wednesday, the 19th inst., so there is not too much time to waste before seeing a show that is solidly and thoroughly good. Failure to see it will be regretted.

F. C. Tilney.

FORTHCOMING EXHIBITIONS

March 27 to April 8.—Dennistoun Amateur Photographic Association. Particulars from the Exhibition Secretary, Colin Graham, 448, Duke Street, Dennistoun, Glasgow.

April 4 to 19.—Royal Photographic Society. Prints by Dr. H. B. Goodwin. Open daily from 11 a.m. to 5 p.m. 35, Russell Square, London, W.C.2.

April 5 to 8.—Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

April 5 to 8.—Faversham Institute Photographic Society. Particulars from the Hon. Secretary, W. H. Evernden, 116, West Street, Faversham.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Anger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography."

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents: applications and specifications—are treated in "Photo Mechanical Notes."

Applications Mar. 13 to 18:—

Films.—No. 7,625. Developing, etc., photographic films. P. L. Burger.

Applications, March 20 to 25:—

Flashlight.—No. 8,362. Flashlight pistols and apparatus for photography or signalling. W. S. Crapper.

Mounting.—No. 8,436. Mounting of photographs. T. H. M. Green.

Print Drying Apparatus.—No. 8,057. Apparatus for drying photographic prints, etc. Kodak, Ltd.

Colour Cinematography.—No. 8,584. Method of producing cinematographic projections in natural colours. W. Spath.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Colour Screen Plate Processes.—No. 175,373. (November 10, 1920). The method of producing a positive transparency in

natural colours, which consists in making a negative of a subject on a sensitive photographic support having a permanent colour screen of different coloured elements, making a monochrome positive from this screen negative on a surface coated with a panchromatic emulsion, and mounting the monochrome positive in registered position with a colour screen identical with or a copy of the screen through which the negative was taken. Florence Maude Warner, Hotel Pennsylvania, 7th Avenue, and 34th Street, Borough of Manhattan, City, County and State of New York, United States of America. The details of the specification are given on another page in the "Colour Photography" Supplement.

THREE-COLOUR PRINTS. No. 175,003 (October 30, 1920).—The invention consists in a process of making three-colour prints in which two chemically toned images and one pigment or dye image are superimposed. According to one form of the process, the pigment image may be provided by a magenta carbon print (which may be modified by flavazine or naphthol yellow or a mixture of the two). The blue-green and yellow impressions may be produced respectively by iron-ferricyanide and mercury-iodide-ferricyanide toning.—John Frederick Shepherd, 10, Derwentwater Road, Acton, London, W., and Colour Photography, Ltd., 3, St. James Street, London, S.W.1. Further particulars of the process are given on another page in the "Colour Photography" Supplement.

STOPS FOR STEREOSCOPIC OR RELIEF EFFECTS.—No. 175,466 (December 6, 1920). The invention comprises a construction of lens stop in which a central aperture is used surrounded by two or more apertures, the apertures collectively producing with a lens a double viewpoint or stereoscopic effect, the characteristics of

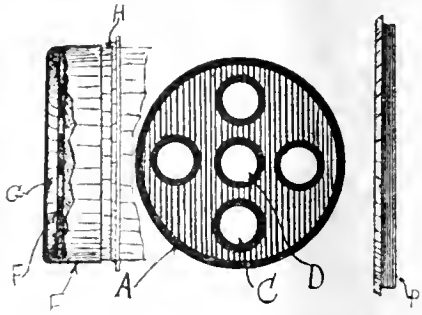

Fig. 5 Fig. 1. Fig. 2.

which are similar to those seen in photographs taken with a stereoscopic camera when viewed through a stereoscope.

The stop may be applied to lenses for taking stereoscopic photographs, also to lenses used for projecting photographs on to a screen.

Improved stereoscopic or relief effects are produced by the application to the front part of a lens, or again, by the application to the back part of a lens, of a stop having a central aperture as at D with two or more apertures C surrounding this central aperture D as illustrated in figs. 1 and 4.

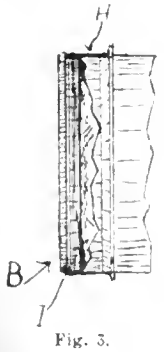

Fig. 3.

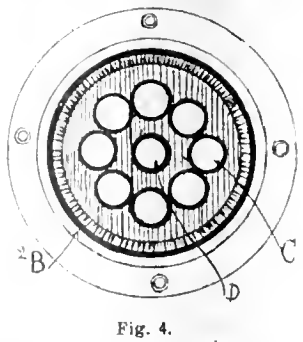

Fig. 4.

The apertures are arranged so that they come within the circle, A, fig 1, of the lens surface.

The apertures may be circular or otherwise in shape varying in size and number to meet the varied requirements of the photographer.

The feature of the invention lies in the provision of a central aperture with two or more apertures surrounding this central aperture. Fig. 1 shows a stop with four apertures surrounding a central aperture. Fig. 4 shows the front elevation of a lens with a stop in position having a central aperture with eight apertures surrounding this central aperture. Fig. 2 illustrates one convenient form of holding the stop in position, it is the side elevation of a flange B 1, provided with a screw to screw into the front or back portion of a lens mount. In fig. 3, B shows the same in position within the lens mount H, immediately in front of a lens I. Fig. 4 illustrates a front elevation of the same lens with the flange and stop in position for taking a photograph.

Fig. 5 illustrates another method of applying the invention, comprising a slip-on or socket arrangement E. This is made to slip over the lens mount H, and is provided with a lip G, that presses against the stop F, holding same in position within the lens mount H.—Thomas Henry Pemberton, 35, Leigh Street, Burslem, Stoke-on-Trent.

The following complete specifications are open to public inspection before acceptance:—

FILM STRIPS.—No. 176,759. Apparatus for use in the treatment of strips of photographic film. F. J. M. Hansen.

COLOUR PRINTS.—No. 176,777. Apparatus for the reproduction on paper of Autochrome and other plates in their proper colours. E. Bueno.

CINEMATOGRAPHY.—No. 176,780. Projection of moving pictures. Bardy Motion Picture Machine Co.

SOUND PHOTOGRAPHS.—No. 176,796. System for the conversion of sound waves into light variations to be photographically recorded on sensitive films. I. H. Hakken.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

ARISTAR.—No. 421,982. Sensitised plates, sensitised films and chemical substances used in photography. Bloom's, Ltd., 7, Ridgmount Street, London, W.C.1, opticians and photographic dealers. January 3, 1922.

ARISTAR.—No. 421,983. Cameras, lenses and measures used in photography. Bloom's, Ltd., 7, Ridgmount Street, London, W.C.1; opticians and photographic dealers. January 3, 1922.

ANAPLAS REPRODUCTIONS.—No. 421,790. Etchings, photogravures, reproductions of oil and water-colour paintings, photographs and drawings. Cecil Philippson, 29, Mincing Lane, London, E.C.3. general merchant. December 23, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

D 50 (HEXAGON NUT DEVICE).—No. 409,867. A photographic developer. Chemicals and By-Products, Ltd., Rickmansworth Road, Watford, manufacturing and consulting chemists.

IMPEX.—No. 411,021. Photographic sensitised paper. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2, manufacturers of photographic materials.

DESENSITOL.—No. 411,785. Chemical substances used in photography, photographic plates and photographic films. Ilford, Ltd., Britannia Works, Roden Street, Ilford, Essex, manufacturers of photographic plates, paper and films.

PROXAR.—No. 362,972. Optical instruments. The firm trading as Carl Zeiss, 2, Carl Zeiss Strasse, Jena, Germany, manufacturers of optical and philosophical instruments.

UNIVERSUM.—No. 382,665. Sensitised films for photography. Universum-Film Aktiengesellschaft, Unter den Linden, 56, Berlin, Germany, manufacturers.

FAERIE CINEMA.—No. 409,603. Photographs. William Rampling Rose, 22, Bridge Street Row, Chester, Cheshire, manufacturer.

AYNONA.—No. 412,797. Photographic papers. John Aeron-Thomas, Dolgoy, West Cross, Glamorgan, manufacturer.

PASTINELLO.—No. 413,292. Projection screens for motion picture theatres and for other optical projection apparatus. The firm trading as Bardilis, 73, Great Titchfield Street, London, W.1, manufacturers.

KINATOME.—No. 413,806. Cinematograph projection apparatus. Herbert George Ponting, 47, Oxford Mansions, Oxford Circus, London, W.1, company director.

New Books.

Blue Printing and Modern Plan Copying. By B. J. Hall, M.I. Mech. E. London: Sir Isaac Pitman and Sons. Ltd. 6s. net.

As a large maker and user of iron printing papers and of apparatus for their employment, Mr. Hall is exceptionally well qualified to write for the information of engineers, architects, contractors and others, having occasion to carry out the multiplication of plans and drawings by the processes which are commonly known as "blue printing." He does not deal with the preparation of these papers, but with their use, and, as regards the latter, confines himself to the three papers now commonly employed, namely, ferro-prussiate, ferro-gallic and sepia, with the addition of the process which has gained greatly in importance of late years and is most generally known as the "true-to-scale." In the chapter on the comparative costs of these methods of reproduction there is a valuable table showing the variation in relative cost, according to the number of copies from a single tracing. Thus, if one copy only is wanted ferro-prussiate paper is about one-third the cost of true-to-scale, whilst if twenty prints are needed the cost per print by ferro-prussiate is roughly one-third more than by true-to-scale. Apparatus forms the largest and most important part of the book, and the author fully describes the equipment for printing by daylight and electric light, including the modern machines for continuous copying. Of late years machines for washing and drying have come into use on a no less considerable scale than those for electric printing, and have made possible the production of immense batches of prints within a working space which would have been altogether inadequate under the old conditions of flat baths and atmospheric drying. The true-to-scale process is the subject of several chapters in which the technique of this process is very fully the subject of instruction. We know of no other manual or publication in which the manipulation of the jelly surface to which the image of a blue print is transferred is so fully and practically considered. The use and merits of the Photostat daylight copying camera are also included within the scope of the manual. Throughout, the author writes as an engineer intimately familiar with the methods and machines with which he deals, and the manual can certainly take its place as a most reliable and complete instruction volume in the important branch of work of preparing "photo-copies" of industrial and commercial drawings and documents.

Kinematograph Studio Technique.—This little volume, published in the series of the "Technical Primers" of Sir Isaac Pitman and Sons, Ltd., provides a rapid review of the methods which are employed in the production of drama cinema films. After a brief description of studios and their methods of illumination, the author, Mr. L. C. Macbean, explains the system which is followed in arranging stage settings and backgrounds in accordance with the scenario of a piece. In this portion there are some definitions of terms used by scenario writers which will be of service to those with aspirations in this field of dramatic creation. Then follow some notes on costumes and make-up and on the choice of outdoor scenes. Stage management of a scene which is in preparation for recording by the camera and the methods of producing the effects of dissolving, fading, etc., which are conventions of the cinema performance are the subject of a further chapter; and the volume concludes with notes on development of negative and positive films and on the electric equipment of a studio. Plainly within such a small compass it is not possible to do more than describe in the briefest outline the methods which are employed. Nevertheless the author has contrived to bring a good many items from his own practical experience into the pages of the book. The price is 2s. 6d. net.

Royal Institution.—Lectures at the Royal Institution after Easter will be resumed on Tuesday, April 25. On Thursday afternoons there will be two lectures by Prof. E. H. Barton on "Audition and Colour Vision." On Saturday afternoons there will be two lectures by Prof. C. W. Richardson on "The Disappearing Gap between the X-ray and Ultra-Violet Spectra."

New Materials.

Embossed Seals and Labels.—Mr. F. C. Clarkson, 57, Charminster Road, Bournemouth, sends us samples of the embossed seals and labels produced in a great variety of shapes, designs and colours for attachment to photographers' mounts and other stationery. These stickers are supplied in lots of 5,000 and upwards at prices which, in popular sizes, average 5s. 6d. per thousand for 5,000 lots; 4s. 6d. per thousand for 10,000.

Gramme Self-Ortho Plates.—Messrs. Griffins, Kemble Street, Kingsway, London, W.C.2, send us samples of this new plate of the self-screen class, which readily yields negatives of good vigour with quite a considerable degree of orthochromatic correction without the use of a light filter. Probably a plate of this kind is now the most popular choice of the more informed amateurs, to whom an addition to the brands among which they may make choice will be welcome.

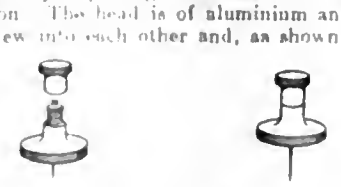
Cream Tone Noctona Gaslight Paper.—Messrs. Griffins have added a new grade to the varieties of their popular gaslight paper of this name. It is of an agreeable pale buff tint and smooth surface, that is to say, without gloss, and equally without definite matt effect. The paper is handled exactly in the same way as the other grades of "Noctona," and, like them, exhibits an excellent latitude in the results from different classes of negative, yielding prints of rich black colour and freedom from stain.

Griesbaber Plates and Papers.—Samples of the whole range of products manufactured by the old-established Paris dry-plate firm of Griesbaber Frères et Cie are sent to us by the wholesale agents for the United Kingdom, the Anglo-French Photography Co., 46, New Kent Road, London, S.E.1. Messrs. Griesbaber have a very full range of dry-plates, from their Blue Label of speed 20 H. & D. to their Special Portrait for half-watt lamps of 500 H. & D. In the case of almost all the plates rated at 200 H. & D. and higher, each speed is made in three varieties—an ordinary, an orthochromatic and an anti-halation. The firm also makes special orthochromatic plates, an anti-screen plate, the Integrun, for use without a light-filter, in addition to a panchromatic. Transparency or lantern plates and also X-ray plates are included among its products. All these plates are supplied in a large number of English sizes, from 2 ½ x 1¾ to 24 x 20. They are, of course, also made and listed in the Continental centimetre sizes.

Printing papers are represented by a similarly wide range. Bromide paper is made in three grades of contrast, normal, soft and special contrasty for thin negatives, in each case in glossy, semi-matt and smooth matt surfaces. These same surfaces are obtainable in a special grade of bromide paper, issued as "Dora," giving warm black or brown tones by direct development, according to the degree of exposure. Ordinary P.O.P. and "Automatic" (self-toning) paper are also among their manufactures, all of these papers being issued in postcards of the regulation 5½ x 3½ size. A detailed 8-page price list is obtainable on application from the Anglo-French Photography Co.

New Apparatus.

Penrose Push Pins.—Messrs. A. W. Penrose & Co., Ltd., 109 Farringdon Road, London, E.C.1, kindly send us one of the new push pins which they are just placing on the market. The pin is of quite novel construction. The head is of aluminium and is made in two parts, which screw into each other and, as shown in the drawings,



allow of almost any ordinary pin being inserted. As supplied, the pin proper is of stout gauge and non-rustable surface, so that there is no reason to think that renewals will be frequently required. Nevertheless, it is certainly an advantage to be able to use the metal heads indefinitely. The complete pins are supplied at the price of 3s. per dozen, or 30s. per gross.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, APRIL 9.

United Stereoscopic Society. "Picturesque Devon." J. A. Hodges. And 1919 Competition Slides.

MONDAY, APRIL 10.

City of London and Cripplegate P.S. "Work on the Negative." B. C. Wickison, F.R.P.S.
Southampton Camera Club. "Pictures Without Words."
South London Phot. Soc. Annual General Meeting.
Walthamstow P.S. "Simple Control in Enlarging" and "Mounting." W. H. Reece.

TUESDAY, APRIL 11.

R.P.S. "Photographic Portraiture, Pure and Simple." Dr. H. B. Goodwin, F.R.P.S.
Belfast C.P.A. Camera Club. "Demonstration of Carbro Process." O. D. Walton.
Bournemouth C.C. Beginners' Instructional Evening. J. Thomas.
Cambridge Photo. Club. "A.P. and P." Prize Slides.
Exeter Camera Club. "Car-Bro." A. Dordan Pyke.
Hackney Phot. Soc. Annual Sale.
South Shields P.S. House Exhibition of Members' Prints.
Stalybridge P.S. "Seltona Lecture and Demonstration."

WEDNESDAY, APRIL 12.

Borough Polytechnic P.S. "How a Reflex Camera is Made." Messrs. Butcher.
Croydon C.C. "Colour Vision." F. C. Reynolds.
Forest Hill and Sydenham P.S. "Panchromatism and Colour Filters." H. G. Fleck.
Ilford Phot. Soc. "Hints, Dodges and Gadgets."
Partick Camera Club. Members' Lecturette Night.
Photo-micrographic Society. "The Mycetozoa." A. E. Hilton.
Rochdale Amateur P.S. Beginners' Troubles.

THURSDAY, APRIL 13.

Gateshead Camera Club. Members' Night.
Hammersmith Hampshire House P.S. "In a fair ground, yea, Sussex by the Sea." J. Grice.
Optical Society. Ordinary Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 4, the president, Mr. W. L. F. Wastell, in the chair.

Mr. Herbert Lambert delivered a lecture entitled "Imaginative Portraiture." He began by illustrating the distinction between imaginative and merely reproductive work by instancing Wordsworth's poem of the old leech gatherer, a thing of art made from material which in the hands of, say, a newspaper reporter would have been something utterly commonplace. When he proceeded to turn from the art of writing to those of the painter and the photographer, he was, perhaps, less explicit in defining the qualities which resulted from the exercise of the imaginative faculty. In fact, he confessed that while it was easy to describe what those results should not be it was exceedingly difficult to put into words what they should be. Mr. Lambert resorted to illustration and showed a number of examples of photographic portraiture which in his judgment exhibited the quality of imagination. These included work of Craig Annan, A. L. Coburn, Marcus Adams, Malcolm Arbuthnot, Walter Benington, Frederick Hollyer and one or two of his own. If he did define the quality common to these works, it was by saying that the imaginative work created in the observer's mind an impression of the moral, human, and intellectual personality of the sitter, as distinguished from his mere facial characteristics. Mr. Lambert had some interesting things to say on the function of lighting in bringing out this rendering of character. He emphasised the important part which it played, and strongly expressed his view that the rules of conventional lighting (the angle of 45 deg.) could often be broken with advantage. On the other hand, he severely condemned the mere tricks of complex lighting done simply with the object of introducing accents and splashes of light in the composition without relation to the study of the face. He called this simply "playing about with lights." It was a bad thing unless it was done with a clear motive, namely, that of contributing to the photographer's aim in making a character study.

The papers aroused a somewhat animated discussion in which were joined Messrs. C. P. Crowther, W. Thomas, Marcus Adams, Furley Lewis, George Hawkings and Dr. H. B. Goodwin. The latter is to lecture next week on "Photographic Portaiture, Pure and Simple," and in his contribution to last Tuesday's discussion gave evidence of the vigorous and explicit expression of his views which may be then expected.

On the proposition of the chairman, a very hearty vote of thanks was accorded to Mr. Lambert.

CROYDON CAMERA CLUB.

Mr. E. Human, of the "City Sale & Exchange," Sloane Square branch, read an interesting paper on "The Possibilities of a Small Camera." Accompanying him was a basket of enormous size from which he extracted camera after camera and accessories galore.

A well-reasoned and persuasive plea was advanced for the stereoscopic camera, and the strong points of the "Verascope," and other beautifully made and scientifically designed midget plate and film stereo cameras were fully described with various stereoscopes and other apparatus. Most of the goods certainly cost good money, and appeared to be well worth the prices charged, which, he said, had recently been reduced.

Perhaps the most remarkable feature of the evening consisted of enlargements of very high magnifications from the tiny originals. They amply demonstrated the splendid defining powers of the objective fitted to the cameras.

Prior to the proceedings an informal dinner at the Greyhound Hotel took place, with Mr. A. F. Catharine as the guest of the club. Unfortunately for it he is leaving Croydon, and the club will see him but seldom. He will be badly missed.

Nevertheless, the members kept their peckers up, and the atmosphere of extreme geniality which blew in with their arrival, accompanied Mr. Human throughout the evening. An atmosphere, if not exactly conducive to true binocular vision, undoubtedly assisting in the direction of general appreciation. A most hearty vote of thanks was accorded the painstaking lecturer.

FOREST HILL AND SYDENHAM PHOTOGRAPHIC SOCIETY.—Lecturing on "Flashlight Photography," Mr. J. A. Webberley showed a flash lamp of his own design, made from an ordinary flint-wheel gas lighter, to which a grooved tray of tin had been soldered at right angles. Using 15 grains of a mixture of equal parts of saltpetre and magnesium powder, fully exposed negatives of members were obtained with an aperture of f/6. By the use of Hypono hypo-eliminator, followed by a soaking in a saturated solution of potass. carbonate (which dried the plate in a few minutes), gaslight prints were made from the negative within 25 minutes of the time of exposure, demonstrating the ease with which photographs can be quickly obtained in the absence of daylight. Holding the flash lamp well above the head was advocated as securing better lighting than at camera level, and the use of fast ortho. plates was to be preferred.

Commercial & Legal Intelligence.

AT THE LONDON BANKRUPTCY COURT, on Friday, March 31, the first meeting of creditors was held of Albert Young, trading as Fradelle & Young, 41, Museum Street, London, lately carrying on business at High Street, Notting Hill Gate, London, Technical Photographer, against whom a receiving order was made on March 16, 1922, on a creditor's petition, the act of bankruptcy being non-compliance before Feburary 3, 1922, with the banruptcy notice duly served upon him. The Official Receiver, Mr. Walter Boyle, having dealt with the proofs of debt lodged, said the debtor had not surrendered under the proceedings, and that an inspector had attended at 41, Museum Street, W.C., but did not see the debtor. On the premises there was a typewriter, photo-stand, screen, steps, large camera, screens, oak fireplace, four large alabaster electric globes, dark-room requisites, and a clock. The inspector had also attended at 37, High Street, Notting Hill, but nothing was known of the debtor there other than that he lived there some nine or twelve months ago, and there was no property, books or papers there belonging to him. A creditor present said the debtor used

to take photographs at Masonic and other banquets, and he believed at one time he was doing very well. The estate was left in the hands of the Official Receiver.

NEW COMPANIES.

Oil Portraits, Miniatures and Artcrafts, Ltd.—This private company was registered on March 30, with a capital of £1,500 in £1 shares (500 partg. preference and 1,000 ordinary). Objects: To take over the business of painters and producers of oil and other portraits and miniatures, general artists, photographers and picture-frame makers, etc., carried on at 60, Spring Bank, Hull. The first directors are: S. P. Roberts, 60, Spring Bank, Hull (managing director); H. Croasdale, 36, Walmsley Street, Spring Bank, Hull; secretary, H. Croasdale. Registered office: 60, Spring Bank, Hull.

News and Notes.

Photographic Society of Ireland.—The hon. secretary is now Mr. H. E. Webster, "Avonmore," George's Avenue, Blackrock, Dublin.

Houghton's Professional Bulletin for March contains announcements of reductions in the prices of several lines of goods, notably mounts and mounting boards, and some account of recent introductions.

Wallace Heaton Bargains.—The latest mail order price list of second-hand and other cameras issued by Messrs. Wallace Heaton, 84, High Street, Sheffield, contains particulars of a very great variety of roll-film and other cameras, lenses, enlargers and miscellaneous accessories. Sent free on application.

More Camera Smuggling.—At Dover, last Saturday, when a fine of £10 17s. for attempted smuggling was imposed on F. W. Chambers, of Dublin, it was stated that when he landed from the Ostend boat a camera was found wrapped in a shirt at the bottom of his bag.

Photographing the Sun's Eclipse.—The daily Press report the landing of 6½ tons of photographic and scientific instruments at Singapore ready for shipment to Christmas Island, from which place the eclipse of the sun is to be officially observed and photographed next September.

Thieving for Photography.—A junior clerk, aged 18, was bound over at Newcastle-on-Tyne last week for the theft of £2, which he spent on photography. Prisoner was in charge of a cash-box, and thousands of pounds had passed through his hands. His salary was £50 a year. The Bench expressed the opinion that the remuneration paid for such a responsible position was not at all adequate.

Burglars Use a Dark-room.—A cleverly planned, but only partially successful, safe robbery was carried out one night last week on the premises of Mr. D. P. Roberts, chemist, of West Croydon. The thieves got over a high wall and through a window to the shop. To avoid being seen through the unshuttered front windows, they removed two safes to the photographic dark-room at the back of the shop.

A Link with the C.D.V.—One of last Sunday's newspapers, in recording the death of the ex-Emperor Karl of Austria, states that the ex-Empress is a descendant of the Duke of Parma, who in 1857 invented the C.D.V. size of portrait. The ex-Empress was Princess Zita of Bourbon-Parma (writes a correspondent), but efforts to trace her exact relationship to the C.D.V. Duke have failed—it must be very remote.

Kodak Posters.—The large Kodak poster just issued is a delightful reproduction in colours of a work by John E. Sutcliffe, showing a red-haired Kodak girl on a bridge over a brook in a picturesque spring landscape. In addition, Messrs. Kodak, Ltd., are issuing a transfer design in colours of another variation of the Kodak girl, which can be readily fixed to the outside of a window and which carries the legend, "Life's a joy with a Kodak."

The Ensign Handbook.—The 1922 edition of this combined text-book and catalogue, issued by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, price 6d., is a plump little volume of 250 pages. The text-book part, consisting of ten chapters by W. L. F. Wastell and Percy G. R. Wright, contains a great deal of practical information expressed in a way which those most slightly acquainted with photography can understand. The catalogue very fully describes and illustrates the many patterns of camera of Messrs. Houghtons' manufacture, and also the various accessories for development, printing and mounting, which the amateur photographer needs to include in his equipment.

A Butcher Dealers' Catalogue.—Messrs. W. Butcher & Sons, Camera House, Farringdon Avenue, London, E.C.4, have just issued an abridged 1922 catalogue, chiefly of amateur requisites. The list, despite its title, is a very full and fully-illustrated catalogue of the British-made cameras and other apparatus which are specialties of Messrs. Butcher. In particular, many of its pages are devoted to accessories, such as printing frames, tripods, finders and washers, dark-room lamps, dishes and tanks. Mounts for the amateur are also a large feature, and a final section relates to cinematograph and optical lanterns. The list is sent free to any dealer making application on his trade card.

Photographic Pitches at Bournemouth.—A reader who has been in correspondence with the Town Clerk of Bournemouth states that the photographic pitches at Bournemouth were sold only to ratepayers of the town. Last year pitches of all kinds (30) were tendered for, when only £775 was realised, but this year's auction of them brought in £2,474. Bidding for the nine photographic pitches was exceptionally keen, their positions and prices for the season being:—West Beach (4), £215 (with kiosk), £50, £40 and £32 10s.; East Beach, £180; Alum Chine, £10; east of Zig-Zag, £30; Fisherman's Walk, £10; and Boscombe Beach, £25. The highest bid (£300) was for a stall for sweets, and the next (£270) for an ice-cream pitch.

A Warning to Dealers.—Paragraphs in the lay Press state that the police are looking for a man who has made hundreds of pounds by stealing binoculars in a novel manner. He enters an optician's as a possible customer and asks to see some binoculars, the prices of the best of which range from £20 to £40. After examining several he selects one pair, which he professes to like and, saying he desires to try their range, walks to the door and holds them to his eyes scanning the street. A moment later he disappears in the throng with the glasses. Dozens of opticians have complained of his thefts, and it is estimated that he has obtained goods worth £500 during the last three months. He is described as tall, well spoken, and fashionably dressed. As we often see possible purchasers of hand-cameras testing finders and lenses at the street doors of our leading stores, dealers will perhaps take a hint, for hand-cameras may go the same way as the vanishing binoculars.

North Middlesex Photographic Society.—This old-established North London society supplies evidence of its continued vitality by issuing a year book for 1922-23, containing a list of members and past-presidents and the full syllabus of papers, instruction lectures and outings up to and including September 28 next. Few societies can point to so complete and comprehensive an announcement of their programmes, and we are sure that the issue of the year book will bring many members within the ranks of the society and greatly to their advantage if they need practical help and assistance and the opportunities for outdoor work under the guidance of those well able to help them. Those of our amateur readers who are within easy reach of the headquarters of the society, which are about equi-distant from the Stroud Green and Harringay Great Northern stations, will be well advised to communicate with the hon. secretary, Mr. W. M. Bond, 24, Henningham Road, Lordship Lane, Tottenham, N.17.

Government Orders Abroad.—In the House of Commons during last week Mr. R. Young asked the Under-Secretary of State for India if he was aware that many optical instrument makers are working short time and others are drawing State unemployment benefit; whether, in spite of these facts, the India Office has placed two orders for prism binoculars abroad; and to which foreign firms have these orders been given, and for what reasons? In reply Earl Winterton said the India Office had placed no orders recently for binoculars, but he was informed by the High Commissioner for India, who dealt with such matters under the direct control of the Government of India, that he had recently placed one order for 5,120 prismatic binoculars with the French firm of Huet & Co. through their English agents. This order was not placed until it had been ascertained that the instruments were suitable. A large financial saving was involved. 6,000 binoculars had been previously ordered from English makers.

A Great French Catalogue.—Mr. W. E. Dunmore, during the comparatively few years in which he has been established in Paris at 22, Rue Saint-Augustin, as a wholesale dealer in photographic requisites, has built up a large business, the wide scope and importance of which is reflected in the catalogue just issued by him. This is a volume of 156 large pages, fully listing and pricing the innumerable goods for which Mr. Dunmore is agent. Articles of French manufacture naturally figure largely in these pages, and the English worker, professional or amateur, will find described many pieces of apparatus which are of interest to him from their novelty. Mr. Dunmore is the agent in France of the Thornton-Pickard Co., of Messrs. Taylor, Taylor and Hobson, and the goods of these firms, as also Imperial plates, Paget papers and Akron dry-mounting tissues, for which he is also agent, figure prominently. Although the list is in French, the illustrations are so numerous that practically anyone without any knowledge of the French language can use the catalogue. Prices are also in francs, but Mr. Dunmore will always quote any given article in English currency. A copy of the list will be sent free to anyone on application.

INVENTIONS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I do not intend to enter into any controversy with Mr. Ives, but as I made a statement, and he has denied the truth of the same, I merely want to put the case as I see it.

The purpose of a non-actinic dye, added to dichromated gelatine or other colloids, is avowedly for the purpose of keeping the relief low, and I have proved that this was done by du Hauron, Lumière and Pfenninger. It would seem to the technical mind that the incorporation of a pigment was immaterial. But obviously to the mind of the inventor there is a big difference; and also to that of the patent examiners. But then one can make these latter gentlemen believe almost anything, as they are, as a rule, utterly ignorant of the practice and literature of photography.

Had Mr. Ives taken the trouble to turn up one or two of the many references that I gave to the Lumière process, he would have found that the sensitive mixture recommended was composed of gelatine, Coignet's hard glue, ammonium dichromate, neutral potassium citrate, cochineal red (aniline), alcohol and water.

In my original paper, "B.J.," 1921, Col. Phot. Supp., September 30, I included Sanger Shepherd amongst those who had anticipated Mr. Ives; but as I had lent my patent files and notes, when I wrote my last letter, I did not include this, as I was loth to trust entirely to my memory. E. Sanger Shepherd and O. M. Bartlett, E.P. 24,234, 1902, state fol. 2, lines 17 to 20: "In order to keep the relief as low as possible is is desirable *to add a colouring matter*, or preferably bromide of silver to the gelatine solution, as the latter may be easily removed after printing by a solution of hypo-sulphite of sodium."

The use of the dye is not included in the corresponding D.R.P. 161,519, 1902, and U.S.P. 728,310, 1903.

Further references to this patent will be found in J. Camera Club, 1903, 18; "B.J.," 1902, Vol. 49, 913, 1,015; 1903, Vol. 50, 50; Handbuch, 1917, Vol. 4, 11, 319 Jahrbuch, 1903, 451; Phot. Woch., 1903, 28; Amat. Phot., 1903, 310.

This patent refers to the making of colourless relief images, which are subsequently stained up for the imbibition or transfer process to other receptive surfaces.

It is clear, therefore:

(1) That MM. Lumière anticipated U.S.P. 980,962 by ten years; (2) that Shepherd and Bartlett anticipated the same by eight years. And Mr. Ives states: "There cannot be found a single anticipation of my addition of a non-actinic water-soluble dye in the sensitised colloid coating, exposing said sensitive coating to light, developing the print, discharging the dye, and then subjecting the print to its appropriate dye bath."

In both the above cases a water-soluble, non-actinic dye was used, a colourless relief obtained, which was subsequently stained up in its appropriate dye bath.

With reference to White's camera, Mr. Ives says that this infringes the claims of his U.S.P. 531,040, and that my statement, that it is the same as E.P. 2,305, 1895, is not entirely true. I did not mean that the two were literatim et verbatim the same, but that the object patented was the same. I have very carefully compared the two patents, and they are in text, with minor exceptions, materially and essentially the same. In the American patent there are 11 claims, in the English seven; and the following shows the similarity: U.S.P. claims 1 and 2 are the same as E.P. 1 and 2; U. 5 is E. 3; U. 7 is E. 4; U. 8 is E. 5; U. 10 is E. 6; . 11 is E. 7.

There are thus claims 3, 4, 6, and 9 in the American, which are unaccounted for. Claim 9 is for a chromoscope having *a*, that is one, transparent mirror at an agle; claim 6 is for a chromogram; claim 4 is practically the same as E.P. 1, with the addition of means of varying the angle of the instrument in respect to the incident light; claim 3 is for a series of inclined mirrors, colour screens, and series of chromogram supports one above another.

The whole essence of the two patents is for a viewing instrument, though in the American patent there are six lines, out of a total of 442, in which the possibility of using it as a camera is outlined: "And by the use of suitable lenses and colour screens and the substitution of plate-holders for the chromogram-holders, either form of instrument may be adapted for making the chromogram negative as well as for exhibiting the chromogram." With this exception, and the title, preamble, and the first two claims, there is not the slightest suggestion of a camera. In the English patent the same passage occurs, and in the title, not the preamble, and in five claims the word "camera" is used.

Mr. Ives' statement that the White camera infringes his patent carries no weight at all. If we are to believe this, Mr. Ives must quote the actual claim and show where it is infringed.

One cannot be plaintiff, defendant and judge all at the same time.

If the statement, "obviously, my claim to the original invention of a specific type of camera is not discredited by the fact that some years after some one made one with one of the mirrors at a different angle," means that he invented this type of camera, then it is not true. Mr. Ives himself states in his U.S.P., fol. 3, lines 40 to 48, "the arrangement of images in steps and the reflection of the light passing through three images by means of transparent mirrors *is not new*, but in the only prior device with which I am familiar, the steps were perpendicular to the base of the instrument, and the transparent mirrors were glasses with parallel surfaces, which doubled the outlines of the respective images."

I have already sent you, Gentlemen, some notes on chromoscopes, and it will be abundantly clear from these, should you publish them, that Mr. Ives was again anticipated by Cros and du Hauron in this type of instrument.

Mr. Ives' attitude is curiously unfortunate for him. For if the alteration of the angle of a mirror, and, consequently, the complete design of the instrument, is an infringement of his patent, then by the same reasoning he himself has no valid patent.

Although this letter is somewhat lengthy, I crave permission to add yet another quotation, from the "B.J." of 1885, where it occurred in a controversy, very famous in its day, but which, being dead, is better allowed to remain so: "Moral objections exist to the recognition of any persons as authorities in photography, if they claim, as their own, discoveries previously made by others, because they promulgate them with a louder voice."—Yours faithfully,

Wollaston, Mass. E. J. Wall.

KEEPING TO ONE SHUTTER-SPEED EXPOSURE.

To the Editors.

Gentlemen,—In reference to the letter of Mr. L. T. Woods in your last issue, Mr. Sanderson will hardly thank him for his championship, for, as the report of the latter's lecture expressly stated, and, I believe, correctly, all his exposures on varying subjects in Italy were made at 1/100th of a second at *f*/6.5.

It is therefore unkind of Mr. Woods to say "I will not insult your intelligence by telling you exactly how I regulated exposures by the use of stops larger and smaller than *f*/8." I can, however,

assure your correspondent (whose identity is known to me) that Mr. Sanderson showed every sign of intelligence in advanced degree, even if his particular method of exposing plates is open to debate.

Mr. Woods' "new idea" is, of course, as old as the hills, and, as has been frequently pointed out, is the only method of regulating "instantaneous" exposures in cheap one-speed shutters. Apart from this, it is a little difficult to understand why "the system is of the utmost value."—Yours truly,

THE CLUB REPORTER.

To the Editors.

Gentlemen,—I observe that in your current issue a correspondent, Mr. L. T. Woods, indulges in a little sarcasm at the expense of the Croydon Camera Club.

Unfortunately, however, he entirely misses the point of the discussion which arose out of Mr. W. Sanderson's recent lecture.

As one who has used (and advocated) a constant shutter-speed exposure whenever possible, for at least twenty years, I should like to call attention to the fact that the criticism of Mr. Sanderson's 1/100 sec. was upon the point of its duration, and not its constancy.

Mr. Sanderson used 1/100 sec. at *f*/6.8 or thereabouts, and the contention was that some of his shadows showed signs of under-exposure. Surely it will be agreed by all that where both foreground figures and distant building are required in sharp focus an exposure of 1/30 sec. at *f*/11 would be preferable to 1/100 sec. at *f*/6.8.

At the same time this leaves a three-fold margin of power for opening up when the failing of light or depth of shadows calls for increased exposure. Mr. Woods' 1/30 sec. on his reflex is an excellent average, but personally I favour a longer time and have found 1/20 sec. fast enough for all average work, while with a box-form camera I have exposed some hundreds at as slow a speed as 1/5 sec. This permitted the use of a K.II. screen with *f*/8 for average work in our uncertain climate.

In conclusion, I feel I must express my regret that the cordial spirit of the Croydon discussions is somewhat lacking in your correspondent's letter.—Yours faithfully, V. JOBLING.

Carshalton. April 3.

PLATINUM TONING OF BROMIDES.

To the Editors.

Gentlemen,—As a practical worker and a one-time user of platinum for toning bromides I should like to support your "Ex Cathedra" remarks concerning the unsatisfactory and fugitive character of the results obtained.

When, in 1902, Mr. Somerville read his paper on the subject before the Royal Photographic Society, I was attracted by the process and the results shown, and produced many toned prints, most of which I have to-day. At the time of making, the platinum tones were particularly rich and of great beauty, but they began to "go" within about a year, and they have been going ever since. I am keeping them (many framed and exposed to light) just to see what the real end of them will be.

The inventor changed his methods of production several times, ringing the changes—if my memory does not play me false—with perchloride of platinum and potassium chloroplatinite, the latter being the better of the two.

Not having the facilities for toning a 20 × 16 print required, I approached Mr. Somerville, who toned it for me, he being a worker who produced very large sizes. This particular print (toned in 1903) has been hanging, framed, in a living room, in which have been plenty of gas fumes and above the average of tobacco smoke, for eighteen years. That the test is a rather severe one I willingly admit, but other toned and untoned bromides have been its companions during this period, and their "countenances" have not changed to any appreciable extent.

Of this platinum-toned enlargement only the centre part is distinctly visible to-day, the edges have changed to a yellowish tint, and over them appears a curious metallic sheen, while across the centre of the print runs a yellowish (faded) mark, the said mark being the place where the two pieces of backboard used in framing meet, thus admitting air. True, the process is far from being satisfactory. Indeed, I have some uranium-toned prints that have kept better.—Yours faithfully,

GODFREY WILSON.

NEGATIVES OF VICTORIAN ROYALTIES AND CELEBRITIES.

To the Editors.

Gentlemen,—A recent issue of the "British Journal of Photography" quoted a daily Press report of the death of Mr. Chas. Taylor, of Chislehurst, former photographer to Royalty by appointment, and who founded the Camden Studios during the residence of the ex-Empress Eugenie at Camden House, Chislehurst.

His widow, Mrs. Marianne Taylor, is unfortunately left unprovided for. She is 75; there are no children or living relatives on either side.

For many years she assisted her husband in all branches of the work, and has signed orders and testimonials from Queen Victoria.

The widow has a number of negatives, including Royalty and Victorian celebrities, a large show case, etc., and is open to accept any fair offer for the same. Her address is 38, Shirley Road, Longlands, Sidcup, Kent.—Yours faithfully, C. E.

ELECTRIC CURRENT AT POWER RATE.

To the Editors.

Gentlemen,—A question of great interest to photographers is shortly to be fought before the High Court, namely whether current used to produce photographs should be charged at 2d. as for power or at 8d. as for lighting. An electric supply company last year attempted to charge current supplied for photography at 8d. instead of 2d. (the power rate) as previously. In the face of a general protest from the profession this demand was afterwards reduced to 4d.; and for some time past 4d. per unit has been paid by certain photographers for the current they use for taking photographs. This is a mere compromise, and there is no legal guarantee that the companies will not again seek to charge the full lighting rate. The only rates provided for by the Acts of Parliament constituting electric lighting companies are the lighting rate and the power rate. Logically they must either charge at the power rate in operation at the time, or they must charge at the general lighting rate. No company is really entitled to charge a preferential rate to one class of customer or ratepayer or a different rate to that which they charge others of their customers or ratepayers for precisely the same thing. Clearly, therefore, the 4d. rate is an uncertain and unstable compromise—as being less than the lighting rate and more than the power rate.

We contend that current supplied for lighting is for that general illumination which enables us to see what we are doing, either for the purpose of pleasure or for the purpose of work. Again, current supplied as power is legally defined as that supplied for any purpose other than that of illumination. The current used for the making of photographs is obviously no more used *for lighting* than if it were used to actuate a Dowsing radiator or a cinematograph projector. Such current is used for industrial purposes. It serves to make those articles which the photographer relies on for a profit. He lights the room or studio in which he uses the arc or other lamp for photography by current for which he has to pay the lighting rate, but the arc or other lamp does not serve as an illuminant to any greater extent than would a magnesium wire or an explosion of gunpowder.

Until we made a stand last year, professional photographers were apparently prepared to sit down under a charge of 8d. per unit for current which had for years previously been charged at power rate, that is, from 1d. to 2d. per unit. It was not until we urged the Professional Photographers' Association, that the body moved, and as a result of negotiations with the electric lighting company in question the proposed rate of 8d. was compromised at 4d. per unit. We never assented to that compromise, and are now fighting to secure the power rate which is at present 2d. per unit, and was 1d. per unit before the war.

Owing to what we contend is the failure of the Professional Photographers' Association to fight this important matter, we now lay the above facts before photographers generally in the expectation that they will give us their support. Every photographer who uses electric current for taking photographs is concerned to secure the necessary current at ordinary power rates.

Will our brethren help us morally or financially or in both ways to fight the matter to a finish?—Yours faithfully,

WYKEHAM STUDIOS, LTD.

165, Victoria Street, S.W.1
April 4, 1922.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. E.—The following are the addresses for which you ask:—Messrs. Hood & Co., Sanbride Works, Middlesbrough; Messrs. Walter Pearce & Co., St. George's Press, Brentford, London, W.

A. L.—The French manual on "Air Brush Work" is published by Messrs. Charles Mendel, 118, Rue d'Assas, Paris. The most professional photographic journal in German is "Das Atelier," published by W. Knapp, Muhlweg 19, Halle, Germany.

J. N.—As you have the "Almanacs" for the past ten years we would refer you to the issue for 1913, which contains an article on fitting up the dark room, and, incidentally, deals with formulae for safelights. Really it is better to buy safelights than to make them. Messrs. Wratten have a series for different types of emulsion which cannot easily be improved on.

G. W.—There is no need to do anything in order to obtain protection of the copyright in your photographs. The copyright becomes your property automatically by the fact of your taking the views without receiving an order from anybody to do so. We suggest that the little manual, "Photographic Copyright," issued by our own publishers, will serve you usefully on many other points connected with copyright.

A. R.—As you do not say the focal length of your present Cooke lens it is rather difficult to advise you. Presuming the lens is from 6 to 7 ins. focal length it is about the best average focus for views, groups and Press work. The only object in having a telephoto would be to get a focal length of from 12 to 15 ins with your present camera extension. We think you would find that the opportunities for using such a focal length would be comparatively few and far between.

F. N. E.—(1) The reversing methods are not satisfactory with dry plates of the thickness of coating of those generally sold. The method works satisfactorily only with a very thin coating of emulsion, like that on the Autochrome plate, and on one or two very special plates. (2) MM. Lumière, agent Mr. T. K. Grant, 89, Great Russell Street, London, W.C.1, and Paget Prize Plate Co., Watford, Herts. (3) No; ordinary plates of this kind are just as thickly coated as others, and, as already said, are unsuitable for the reversing process.

F. L.—(1) There is no book published on the production of view postcards, but some years ago a series of six articles by Mr G. T. Harris, himself a large publisher of view cards, appeared in the "B.J." of March 29, April 5, 12, 19, 26, and May 3, 1912. These issues can be supplied by our publishers at the price of 2s. 6d., post free. (2) The ordinary enamel will serve as a protective varnish for tin trays to be used for developing, although the coating does not last very long. A more permanent varnish is that sold by dealers in electrical requisites as "anti-sulphuric paint."

H. N.—Hydrofluoric acid, which is the only acid that will attack glass, is such a corrosive agent that we do not think it is possible to prepare a sensitive emulsion which will act as a resist for it in the etching of glass. The resist for glass etching is wax, or similar material, and so far as we know such substances could not be prepared in the form of silver emulsions. The only direction in which experiment might hopefully be made is in the use of sensitive bitumen. By special treatment bitumen can be made much more sensitive to light, but, in any case, exposures are, of course, very much longer than for any silver bromide emulsion.

P. G.—(2) The following is the method for making ox-gall glazing solution:—To the contents of one ox-gall, to be obtained of most English butchers at a cost of about sixpence, add one gallon of water, two ounces of glycerine and two drams of formaline. This will keep almost indefinitely in a stoppered bottle, the quantity required for use each time being poured therefrom into a jar or basin in which the rag used for applying is soaked. This is the ordinary strength for general use; for the first application to new glasses only half a gallon, or less, of water should be used. It is rather a messy business. A specially purified form of oxgall is supplied by Messrs. Rheinlander & Son, Rodney Road, New Malden, Surrey.

F. D.—(1 and 2) If you have a permanent or semi-permanent place of business where people can come and buy the photographs of the groups that you make no licence is necessary, but if you canvas people for orders at the time of taking the groups then, in many districts, the police require you to have a hawker's licence. You should apply to a chief police office for information. (3) No, a certain licence only applies within a given district. (4) To make a 10 per cent. solution dissolve 2 ozs. in water and make up to a total bulk of 20 ozs. If a 40 per cent. solution, dissolve 8 ozs. in like manner. For a 4 per cent. solution it will be near enough to dissolve $\frac{3}{4}$ oz. in like manner, and for a 3 per cent. solution dissolve 263 grs. in like manner.

G. W.—There is no reason whatever why you should not take any views you like, even though there may be in existence and on sale postcards taken from practically the same standpoint which you will choose, and, therefore, very closely resembling the post cards which you will make. The copyright in these existing cards is only infringed by copying the cards themselves. We think you should take the views in the first instance "on your own," that is to say, you should not do them to the order of your trader friend. If you do the latter, the copyright in the works becomes his, and if he liked he could discontinne ordering the cards from you, bnt could have the prints copied and thns deprive you of the benefit of your work. The thing is often done, and, of course, it has the further evil effect that you would be prevented from making a further single print from the negatives in your possession.

J. B.—The usual method of sepia toning, namely with the bromide ferricyanide bleach and sulphide darkening bath, gives dark tones of the kind shown by the specimen with many papers. If, however, you want to ensure darkness of tone, probably the best method is to place the bleached prints for a short time in any diluted and restrained developer, afterwards transferring them to the sulphide solution. This method was worked out by the technical department of the Kodak Co. a year or two ago and works very well, but, of course, needs more skill and supervision than an ordinary method, and has the disadvantage of an extra bath. Really we think your best plan would be to take the ordinary formula, and try a dozen or so different brands of paper, selecting the one which most nearly gives you the tone you are seeking.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3232. Vol. LXIX. FRIDAY, APRIL 14, 1922. Price Fourpence.

Contents.

SUMMARY.

The issue of the "British Journal" for April 28 will contain a full advance notice of the Photographic Fair, and will direct attention in particular to new introductions in photographic apparatus and materials to be seen for the first time at the Fair. (P. 209.)

In a contributed article Mr. A. H. Hall deals with some special points in the working of the Carbro process. He prefers to bleach and re-develop prints on warm tone development papers when making Carbro prints from them. Incidentally he finds that a print from which one or two Carbros have been taken is specially suitable, after re-developing and drying, for Bromoil pigmenting. (P. 212.)

In a leading article we lay stress upon the need of washing before fixing as well as afterwards. Alkali from the developer quickly neutralises the acid of an acid fixing bath. We give some hints also on testing for complete fixation and on washing after fixing. (P. 210.)

Mr. Loyd A. Jones and Milton F. Fillius, in a paper from the Eastman Research Laboratory, describe the experimental methods which they have devised for the measurement of the gloss or mattness of photographic printing papers. The second part of their communication, to appear next week, contains the results obtained. (P. 216.)

Mr. E. A. Dench describes some characteristic styles of window dressing of photographic stores adopted by dealers in the United States. (P. 214.)

Dr. Henry B. Goodwin, of Stockholm, who is now in London, is using his healthy influence against the sham artistic effects shown in much of the modern photographic portraiture. (P. 209.)

The Edinburgh Society of Professional Photographers is considering the question of alliance with the sister Society in Glasgow, with a view to the formation of a Scottish and North of England Professional Photographers' Federation. (P. 221.)

The Lancashire Society of Master Photographers is holding its annual meeting and a conference at Blackpool from May 15 to 20. (P. 221.)

The combination of silver phosphate and an organic ferric salt as the sensitive coating for a photographic printing paper forms the subject of a recent patent specification. (P. 219.)

A wider angle of view may readily be obtained with a given lens by stopping down very greatly and racking the lens nearer to the plate than would be possible if it were used at a larger aperture. (P. 210.)

Many hints on the use and preservation of photographic materials in the Tropics are given by a contributor to the "Camera." (P. 212.)

The Royal Photographic Society will awaken echoes of its early association with the Royal Society of Arts by holding a meeting next month at the house of the latter in John Street, Adelphi. Apropos of this event we refer to the many homes which the R.P.S. has had in contradistinction to its more fortunately housed sister body. (P. 210.)

EX CATHEDRA.

The Fair. Not many days will elapse after the Easter holidays before the Photographic Fair opens at the Horticultural Hall, Vincent Square, Westminster, on Monday, May 1, remaining open until the following Saturday. Photographic manufacturers, dealers, and firms undertaking printing, etc., for the professional photographer will be as fully represented as at recent fairs, which is saying a good deal. Inasmuch as a review of the exhibits of the Fair could be published in the "British Journal" only on the day before the closing, we shall again adopt the plan of publishing a detailed advance notice, namely, in our issue of April 28. Particulars of their exhibits, and especially of new introductions, have been given to us by the exhibiting firms, so that we shall be able to serve intending visitors by way of drawing special attention to new apparatus or materials which will be introduced upon the photographic market at the Fair. As was perhaps to be expected, the number and variety of these new goods are notably greater than at the previous post-war fairs. A glance at the article which will appear in our issue of April 28 will serve to show what they are and at what stands they are to be seen.

* * *

Dr. Goodwin. Dr. Henry B. Goodwin, of Stockholm, the exhibition of whose portraiture is now open at 35, Russell Square, is perhaps as vigorous and fearless a controversialist as any which photography has known since Dr. Emerson stirred the pictorial ranks to their foundations. Yet we are inclined to think that, in the heat of his denunciations of the theatrical and sophisticated styles which now debase so much of the modern portrait work, he has not proclaimed as loudly as he might profitably have done his own creed of a tireless study of people and character and of the technical means of character rendering. We are referring to the few remarks which he made at the Royal Photographic Society last week, and to the address which he was to have delivered last Tuesday, a report of which cannot appear in this issue owing to its earlier publication before Easter. Fortunately, the hundred or so examples of his art, which can be seen at Russell Square until the 19th inst., form as admirable an exposition of Dr. Goodwin's teaching as could be wanted. Their technical perfection is a quality which must not be allowed to obscure the motive of which they are the expression. The portrait photographer ought on no account to miss the opportunity of seeing them, for from them he can obtain the healthiest and most invigorating stimulant to artistic work of enduring value which has been available for a long time. Nobody can look at these portraits of men and women without feeling that, with scarce an exception, they are character renderings of the subjects. Dr. Goodwin has a style, but it is not one which is forced into every portrait he takes, but undergoes numerous modulations appro-

priate to his theme. He and his work are a healthy antidote for the theatricality in portraiture of which we are getting too much.

* * *

Wide Angle Dodges. In these days of expensive anastigmats there are few workers who have the large assortment of focal lengths in their lens kit which was common some years ago, and it is often found that a lens shorter by an inch, or even half an inch, is needed to include the necessary angle. An old dodge which may not be known to all our readers is to use an exceedingly small aperture, say *f*/90, and after focussing to rack in the bellows until the whole of the subject appears on the screen. Theoretically, the definition should be spoiled by diffraction, but in practice this trouble does not arise, the definition being much better than that obtained with a pinhole of very much smaller diameter. Temporary diaphragms may be made from thin vulcanite or even black paper, and should be placed in contact with the leaves of the iris, taking care not to strain the latter. A weak positive meniscus spectacle lens placed close to the front combination will materially shorten the focal length and will not be found to affect the achromatism of the instrument, the small aperture necessary for this class of work covering a multitude of small errors. Old wide-angle rectilinears and portable symmetricals may often be picked up very cheaply, and afford very good investments for the technical photographer.

* * *

The R.S.A.— There has always been a close relationship between the Royal Society of Arts and the (now) Royal Photographic Society, for it was at the Society of Arts that the Photographic Society of Great Britain was housed at the outset of its career. Even during recent years, but before the Photographic Society was as popular as it is to-day, important papers on photography were read before the "Arts" rather than before the "Photographic." The "Arts" also (in 1895) offered cash prizes and medals for photogravure work, and did much to encourage early workers in colour photography. It is announced that the freehold of the premises of the Royal Society of Arts in John Street, Adelphi, where a meeting of the Royal will be held on May 9, has just been secured. The sum required for the acquisition was £50,000. Towards this £42,000 has already been subscribed, one generous donor—who insists on remaining anonymous—having given £30,000. The first meeting of the Society took place at Rawthmell's Coffee House, in Henrietta Street, Covent Garden, on March 22, 1754. The Society eventually entered into a contract with the Brothers Adam to build the premises in John Street, Adelphi, which have now been its home for a century and a half, but only as tenants. At the time the Society was formed there were only two others. One was the Royal Society, which dealt with pure science, and the other was the Society of Antiquaries. The membership now is upwards of 4,000. It is the intention of the Society to restore the interior of the building, so far as is compatible with modern requirements, to the state in which it was left by the Brothers Adam.

* * *

—And the R.P.S. In having the same home for a century and a half the "Arts" has been more fortunate than the "Photographic," the latter having to carry out a long series of flittings. In the first year of its existence the "Photographic" met, as stated above, at the "Arts," but at the end of the year (1854) took rooms for itself at 41, Regent Street (since re-numbered, the original home being demolished about 1885). In 1857 the Society became too large for its rooms and migrated to New Coventry Street, where it remained till 1860. A move was then made to King's College, Strand (too much money being spent in New Coventry Street), where it remained till 1867, when it removed to 9, Conduit Street. There it remained for nine years (till 1876), when straitened resources once more induced a move to the Gallery in Pall Mall. Economy won, and in 1890 the desire again arose for better premises with offices, and a fund was set on foot for the purpose of covering the cost. The result was satisfactory, and rooms were taken at 50, Great Russell Street, where the Society remained until June, 1895, when a move was made to Hanover Square. The move to Great Russell Street gave the Society a new life, and it was here that it forced itself to the front. Moves to Russell Square followed, first to No. 66 (from which address it was driven when the house was demolished to make room for the Imperial Hotel), and last of all to No. 35 on the opposite side of the Square. The early history of the Society's wanderings was dealt with in the President's annual address in 1895. The fullest details of the very earliest struggles of the Photographic Society are, however, those given in the Report of the Jurors of the Photographic Section of the 1862 Exhibition, written by Dr. Diamond.

WASHING, FIXING, WASHING.

BECAUSE the results are not immediately apparent much less care is usually bestowed upon the washing before and after fixing, and the operation of fixing, than upon development in which carelessness and errors of judgment are at once visible.

In many establishments it is now the custom to pass both prints and negatives direct from the developing solution into the fixing bath without even rinsing. This is an unwise proceeding, as not only is it a possible cause of uneven markings, but it quickly introduces into the hypo solution a large quantity of chemicals which no sane person would add in making up a fresh bath. When a neutral or alkaline fixer was generally used this contamination was manifested by the darkening of the solution, but with the acid fixer there is no such warning, and there is great danger of overworking it to the ultimate detriment of the negatives and prints fixed therein. It is therefore a wise precaution to wash away the developer as thoroughly as circumstances permit before fixing.

Most developers contain a fair amount of alkali, and most fixing baths contain but a small quantity of acid, and that acid not a very powerful one. Consequently, the acid content is rapidly decreased and its stain-preventing qualities reduced. It may be thought that development may continue to an undesirable extent during this intermediate washing, but this is a groundless supposition, except in the case of over-exposed bromide prints, when the acid bath serves to stop development. Yet trusting to this is illusory if the acid has been neutralised as we have indicated above. A simple and effective way of washing is to have a large dish of water into which the tap is kept running, and to move the negatives or prints about in it for a few seconds. With negatives, the dish may be dispensed with if a rose is attached to the nozzle of the tap.

The acid fixing bath unfortunately remains fairly clear long after it is capable of doing its work properly, and much trouble, the cause of which is unsuspected, arises. A wise precaution is to note the time taken to remove the visible silver bromide in a newly-made hypo bath and to discard the bath when double this time becomes necessary. At least, double the time necessary for clearing should be allowed for proper fixing, but it is not desirable to allow prints or negatives to have a too prolonged stay in the hypo bath, as with some conditions

of the solution an appreciable reduction of the image may occur. No definite time can be indicated for fixing, as plates and papers vary greatly in this respect. A process or ordinary plate often fixes in a third of the time necessary for a rapid portrait emulsion, while with bromide papers the hardness and permeability of the coating cause a similar variation. A simple test is found in a solution of sodium sulphide of the strength employed in sepia toning. If the plate or film shows the slightest yellowing upon immersion in this it is a sign that the undeveloped silver bromide has not been removed. This explains the fact that some workers cannot get clean whites upon their toned bromides, which often appear as if a cream paper had been used. With imperfectly fixed negatives mercurial intensification gives uneven brownish stains, which will also appear after a lapse of time, when intensification has not been resorted to.

Thorough washing after fixation is upon all hands allowed to be of prime importance, but it is not always carried out. It must be clearly understood that it is not upon the quantity of water that is used, but upon the way in which it is applied, that efficiency depends. Many washing tanks are sadly defective in their action, the plates being too close together, without there being any proper means of securing circulation of the water between them. Even with a plentiful supply of water it is advisable to empty the tank thoroughly several times, so that there is a certainty of fresh water reaching each surface. If this be done the time of washing may be curtailed considerably. A final rinse under the tap, accompanied by a gentle wipe with cotton wool or wash leather, should always be given, as this removes from the surface any deposit of lime from the developer, fixer, or washing water. To prevent "tears" or uneven drying a little dodge recommended by a correspondent, Mr. D. Charles, many years ago will be found effective. It is, to allow the water to flow evenly over the surface and to transfer the plate to the drying rack without allowing the water to run back. It will then recede in an unbroken sheet and leave an even surface. In the winter, or at any time when quick drying is necessary, the surfaces should be blotted off or wiped as dry as possible with a clean fluffless cloth.

Print-washing arrangements are usually even less effective than those used for negatives, by reason of the tendency for the prints to stick together. Nothing is better than hand washing, that is to say, transferring the prints singly from one dish of water to another, six changes with five minutes in each water being quite safe. A useful modification of this is found in the cascade washers which are now becoming deservedly popular. These consist of a series of large trays arranged like stairs with a continuous stream flowing through. The prints are first placed in the lowest tray, and after a few minutes' interval placed in the higher ones in succession. It is, of course, necessary to give a good rinsing to the prints before placing them in this apparatus, or the sojourn in the lower tray will not be very effective.

NOTES ON THE CARBRO PROCESS.

The carbo process, eliminating as it does the need for an enlarged negative, has undoubtedly come to stay, and, worked methodically, the results are certain and can be repeated at will.

Though part of the manipulation bears a close resemblance to that required for the production of a carbon print, there are certain differences which may cause trouble and which are dealt with in the text.

It is assumed that the operations requisite for the production of a carbro print are known, either from the details published in the "British Journal," or from the pamphlet issued by the Autotype Co.

The basis of the process, the bromide print, is of prime importance, and the writer has yet to find a type which will not give good results if the right quality of print is provided, and both here and in the subsequent operations temperatures should be taken. A print which has received less than two minutes' development with a normal developer at 60 deg. F. should not be used.

A print a trifle on the dark side is recommended, though a normal print with rather longer between the period of squeegeeing on to the transfer paper and development will give good results.

Very excellent prints are obtained from weak negatives printed on the glossy contrasty paper so much used for press-work.

The chloro-bromide papers which give warm or brown-black tones will give excellent results if the print is first bleached in the usual ferri-cyanide and bromide bath used in sulphide toning, followed by complete redevelopment. To those who, like the writer, make the majority of their prints on this type of paper, the extra operations are well worth the trouble. The extra depth which is a feature of this type of emulsion is an advantage, and the print should not be too dark. The best print which can be obtained from the negative is just right with this class of paper; and a rather longer immersion in the No. 2 bath, *i.e.*, the bath containing formalin, acetic and hydrochloric acid is advisable, and here 30 secs. can be taken as the normal time.

One of the troubles which has been experienced has been a tendency for the high lights to wash up. A print should on no account be too hard.

As regards the solutions recommended by the Autotype Company there is little comment to make, except that the stock solution of potass ferri-cyanide, bromide and bichromate will in cold weather crystallise out to some extent as regards the bichromate, and, of course, failure will result if the working bath is made up on such circumstances.

During all the operations the temperature appears to be most important, and heavy blocked-up shadows lacking in detail will result if the solutions or the room in which the prints are worked are below 60 deg. F. It is as well to keep as near to 62 deg. F. as possible throughout.

Much modification of the print is possible by varying the time in the No. 2 bath, and this appears to be a point where improvement in the process is possible. The normal time of immersion, 20 secs., is too short, as an error of a few seconds is such a large percentage of the whole as to make a considerable difference.

The writer has not yet experimented with a modified bath, but one timed to give an exact reproduction of the bromide with an immersion of, say, 60 secs., would be wonderful.

Care must be taken in placing the pigmented paper on the bromide to prevent slipping, or a double image may result, and a convenient method of obviating this is to lay a flat boxwood ruler along one edge of the plaster and hold it down tight while the remainder of the print is being squeegeed.

Special boards made with a folding flap to achieve the same result are obtainable.

When the pigmented plaster has been in contact with the transfer paper for 30 minutes—a shorter time is not recommended—the two are placed in water at 95 deg. F. This temperature is lower than is usual for carbon printing, and should be measured with a thermometer, while if the time the pigmented paper has been in contact with the transfer paper before development exceeds 30 minutes a somewhat higher temperature is advisable.

The development is usually quicker than with carbon, and after gentle splashing with water on the face to remove the bubbles which show on the deep shadows, the remaining pigment which is soluble can be easily removed by holding the print under water by one end and shaking it to and fro quickly.

Some trouble has been experienced, and this is not confined to the writer's efforts, in using old tissue which shows a tendency to pull up in the shadows when trying to strip the backing. This, even with pre-war carbon tissue, only occurs at times, and hotter water for stripping should be used; but the tissue now supplied by the Autotype Co. and labelled for carbro works so easily that it is better to get a fresh supply.

As regards the mechanics of the process, if one pigment plaster is immersed in the sensitising solution (normal time three minutes), and after two minutes a second is put in, the two minutes intervening between the time when the first is taken out for immersion in No. 2 solution and the second is ready for the same operation, leaves just sufficient time for the subsequent operation of squeegeeing and placing the first print between waxed paper to be comfortably performed.

As 15 minutes is the time for contact of the plaster with the bromide print, it follows that five prints can be treated one after the other, but as the transfer papers have to be wetted this is rather a rush, and it is better to be content with four. The fourth print having been completed as regards squeegeeing to the plaster in ten minutes, will be ready for its final home on the transfer paper after twenty-five minutes from the start. The first print is ready for development after 45 minutes—*i.e.*, 15 minutes in contact with the bromide and 30 minutes on the transfer—so that 25 minutes having been expended up to and including the fourth print will leave about 20 minutes for a fresh batch to be started, and the earlier operations repeated, before the first print is ready for development. If therefore a second person can be employed for the simple operations of development and aluming, the process can be practically continuous for as long as is required, each print prior to development taking an approximate time of 6½ minutes.

The times of squeegeeing the tissue on to the bromide should be noted in crayon on the back, so that the correct time for contact can be maintained. For those interested in the bromoil process it is worthy of note that a print from which one or two carbros has been taken, and which has been redeveloped and dried, is in a specially suitable condition for this process and will usually be found to pigment exceptionally well.

A. H. Hall.

KEEPING PHOTOGRAPHIC MATERIAL IN THE TROPICS.

[The following article, which we reprint from an American contemporary, "The Camera," describes how difficulties when using films in the tropics were overcome.]

Few travellers go abroad nowadays without a photographic equipment. Yet not many take the trouble to foresee and prepare for the special conditions under which photography must be pursued in the countries visited. The tropics, especially, present all sorts of difficulties. Among dozens or scores of camera carriers whom I have met in two trips to South America, I have encountered no one who had attempted to solve these difficulties. One or two expert photographers were securing a very low per cent. of good negatives, and were taking no special precautions to safeguard those few. And still everyone knows how much good pictures depend on taking care at every step.

Nearly all stages of photography are subject to special troubles due to high temperatures and high humidity. The unexposed film, the exposed film, the processes of development, fixation and washing, the negatives, and all the printing processes must receive special care. My own difficulties were multiplied by the necessity of constant travel, which meant a reduction of equipment and working under makeshift conditions.

I have experienced little deterioration of unexposed film. That problem has been well solved by buying film sealed for tropical use. However, in travelling across the Andes, the decrease in atmospheric pressure at high altitudes caused the foil tubes to bulge, and a few showed evidence of having admitted air. As an additional precaution I kept the films packed well in the centre of packing boxes, surrounded with crumpled newspaper. At convenient intervals I would unpack everything for a thorough drying. When travelling with pack animals, I did not risk the entire photographic outfit in one pack, but distributed it among several loads of material. This proved a wise precaution, for one animal did stumble and fall on his pack while fording a river.

Filmpack has shown less deterioration than roll film in my experience, possibly due to the intervening air spaces. Roll film seemed to improve in this respect when I had learned not to wind it too tightly, after exposure.

Most workers have found the caution against over-exposure an easy one to follow, and live up to it too well. The tendency is often to under-expose through excess of caution. Such is certainly the case in murky weather and in the dense shade of the tropical forest. The result is that many negatives are nicely exposed for the high-lights and make a good appearance, but over-print the details in the shadows. Another trouble which puzzles the newcomer is that a film may become wrinkled and uneven, due to moisture, while in the camera. Of course, some parts of it are then out of focus. This can be avoided only by keeping the camera well protected from moisture, especially during the tropical nights.

The real difficulties begin when the film is exposed. In all climates the exposed film suffers from the continued action of sunlight. That is, when exposure has been made, the affected areas continue growing denser and denser, until after a long time the result is an over-exposure—at least an exposure greater than originally calculated. This effect is apparently heightened in a humid climate, due to moisture in the film. Moisture does not attack all parts of a film surface equally, but in patches, depending on the way air is admitted, and on the contact with the black or ruby paper. The over-exposure is consequently uneven also, so that it cannot be compensated

for in printing. Both before and after development films may be attacked by mold.

Development, fixation and washing are the most fruitful of trouble. When travelling constantly it is out of the question to carry stock solutions, both on account of bulk and rapid deterioration. I have found it advisable to carry a considerable excess of dry chemicals and to make up fresh solution whenever needed. Special care must be taken to keep the chemicals dry in transit. Airtight containers should be used, for the chemicals absorb moisture from the air and become soft and semi-liquid. This makes it difficult to follow the formulæ.

The temperature of the bath is very difficult to regulate. I have taken the temperature of the natural waters of tropical Peru and Brazil in many places. There is almost a complete uniformity—river water and spring water were always near 80 degrees F. This is exasperatingly near the melting-point of the gelatine, and working with it raises its temperature still further—above the critical point. Even when water is allowed to flow about the trays it is too warm to accomplish much. Working with such water is on the border line of impossibility. Tropical developers are designed to extend the range of working temperatures some 20 degrees. I carried a supply of them, but while travelling constantly, did not find conditions suited to their use.

On a few occasions I was able to catch considerable quantities of rain water having a temperature of less than 70 degrees F. If used at once it served very well, through surrounding the baths with the cooler water and changing frequently.

The only really satisfactory arrangement is to surround the baths with ice. By using plenty of ice, exact temperature control can be had. Even then, if the air is humid and the films dry slowly, trouble may appear while the film is hanging wet. But it is only in the larger cities that ice may be had at all. Without the use of ice I have experienced all the following troubles in development: A longitudinal checking of the gelatine, which may or may not disappear on drying; reticulation, pinhole, stain, frilling and loosening of the gelatine, fog, etc. Few perfect negatives were obtained without ice, though a large number of good ones survived through taking all possible care.

The longer the film remains in baths near the melting point of the gelatine the greater is the injury. It is important to remove it then at the earliest possible moment. Certain of my negatives, under-developed by the tank method and intensified on returning home, turned out to be among the best in printing qualities. This suggests that it may be a wise policy to expose well, to under-develop consistently and re-develop later when necessary. Formaline-hardened film is said to be too brittle to allow wetting again, but none of mine showed any loosening of the gelatine in the intensifier.

If working at high temperatures, the developer cannot be used for more than one or two films at most. For that reason it must be used in small quantities and the small two-powder packages made up for amateur use are a very convenient form. Having the fixer strong and fresh shortens the time the film must remain in the solutions. The washing must be reduced to a minimum when warm water is used. Rapid rinsing through several changes is imperative.

More vigilance is necessary in safeguarding the negatives after drying than the sealed unexposed film. They must be kept dry and isolated from each other to prevent mildewing or sticking. If 10 per cent. formaline is used for the last wash water the film is hardened considerably. I have found negative albums the safest means of carrying negatives, and after all they are no more bulky than any other arrangement.

Printing equipment I have always left at home and deferred the pleasure of seeing prints until my return. This, of course, simplifies one's outfit considerably. Bulk may be further cut down by planning to do developing at night and reducing the dark-room outfit. Trays, tank, thermometer and candle lamp will answer. Film clips are of vital importance.

If one is located rather permanently in a large city where ice may be had, it is worth while to equip a dark-room, and most of the above difficulties will be avoided. But in the field such is not the case. From the foregoing account it is clear that one must solve the problem of saving the film in one of two ways—i.e., either one must be able to develop film at frequent intervals under adverse conditions or one must be able to carry exposed film a long time until reaching a suitable place to do his work.

Tropical developers are a more or less successful attempt to solve the problem in the first way. This article is written especially to show how I have met the situation in the second way, as will be seen in the following paragraphs:—

Manufacturers of film warn the user not to seal it again after exposure in the tropics. To do so would enclose a certain amount of moisture with it. They argue that it is better to allow it to ventilate than to sweat in an air-tight container. My attempt has been to find a way of storing film dry by enclosing it in a dry chamber, and the resulting device is shown in the photographs (figs. 1 and 2). If the humidity and temperature are not permitted to become excessively high there is no reason why film should not enjoy as long life in the tropics as elsewhere. Temperature control has not been so difficult as might be supposed. It is mostly a matter of keeping the container in the shade. The obvious solution of the question of

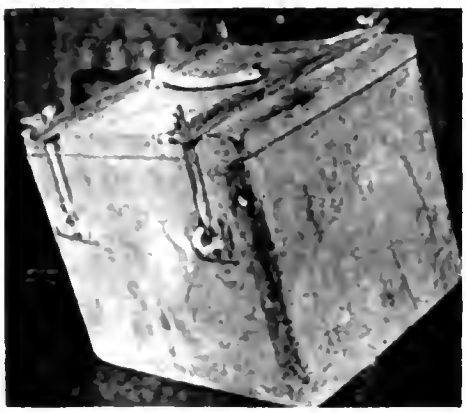

Fig. 1.

Fig. 2.

humidity was to enclose with the film a quantity of a deliquescent salt to absorb water. This I attempted to do with chloride of calcium. But this obvious plan did not succeed, due to the difficulty of drying the salt.

I had about despaired of making the hermetically sealed chamber successful when a very simple solution came by chance. I had dried some old newspapers used for packing and went to

gather them just as the sun was setting. It was a region of heavy dews, and I found the paper already damp when I picked it up. It then occurred to me that crumpled newspaper, easily dried in the sun and readily taking up moisture again, was the thing needed to complete my film-box. From that day forward there was no trouble. The box was kept closed except near the noon hour on bright, sunny days. I never opened it at night, on cloudy days or after recent rains, even to add films. Luckily at such times little film is ever exposed. Whenever a good drying day came I was sure to spread the open box and the crumpled paper in the sun for an hour, and the exposed films in the edge of the shade.

No detailed description of the box is needed, for the idea is quite adaptable, and suited to either the use of crumpled paper or any other desired drying agent. The figures will be a sufficient explanation. Hermetic closure of the box was secured by its soldered zinc lining, its rubber gasket and thumb-screws. The bolts should be battened to prevent the loss of the thumb-screws. The box was made sufficiently large to hold considerable film and two folded cameras. Only in case of great and continued humidity is it necessary to keep the cameras in it.

There are three sorts of evidence which demonstrate that the device is successful:—(1) When the box has been opened after a week or so of wet weather, the paper still felt dry and crisp to the touch. (2) My best negatives are those which were developed at home in a dark-room from eight rolls and filmpacks that had been exposed four to six weeks before in the upper Amazon country. They arrived still fairly free from humidity after a fortnight on the Amazon and an equal period at sea, with no perceptible defects due to dampness. (3) At first I carried my negative albums in other containers. Some negatives were placed back to back by twos in the pockets of the albums. Whenever baggage was opened and spread out to dry, the albums were aired as well. But the negatives were sure to be damp and sticking together more or less. Then I began keeping the albums also in the closed box. They never again felt soft and humid and there was no further sticking. It is reasonable to suppose that the undeveloped exposed film in the box was likewise much drier than it would have been outside.

While I may not have eliminated all film trouble in the above way, I believe I have reduced the risk to a point much below the risk assumed in trying to develop film in warm water. If the traveller has access to ice every two or three months the method will enable him to save has exposed film for a much longer period than has usually been safe, and enable him to wait for suitable working conditions. The method may be worth all the trouble in merely safeguarding negatives.

M. R. Allen.

PUSHING CAMERA SALES.

We have camera enthusiasts with us all the year round. But by far the greater portion of them again take up the hobby with the first touch of spring. Right from then up till the late autumn is the harvest time for cameras and accessories.

You should be there with attractive window displays—window displays which reflect the season of the year.

The Doll Photographer.

The Quality Shop, Washington, D.C., U.S.A., had a pleasing camera display. Seated on an empty camera carton was a large doll. She held the small camera that had come out of the carton. The camera was fastened over the doll's hands with a rubber band, and the doll was posed in the attitude of taking a picture of three "Splash Me" dolls, reposing on an empty camera box at the other end of the trim. A card at the centre front announced: "Look Pleasant, Please."

A Tennis Net for Atmosphere.

Koeniga, Newark, N.J., enclosed the rear of their camera window with a tennis net, which was decorated with seasonable flowers, with photographic booklets hung at intervals. The net was bunched like rosettes at the sides. Cameras were exhibited on the floor of the display.

Studies in Good Times.

Willoughbys, New York City, attracted attention to their display by a series of painted panels. These panels, enclosed in gilt frames, were placed across the background. The first panel showed a gipsy girl carrying a jug of water to her caravan, which was drawn up by the country roadside. The subject matter of the second panel was that of a modern maid having her fortune told under a tree by a gipsy. The third panel dealt with a city chap using his camera in the woods. The middle panel simply bore the following caption :—

"Good Times are in Store with a Kodak."

Cameras and accessories were neatly set about on the floor, with cards describing the uses for each article. Here are some examples :—

"Stop guessing distance. Use McMillan's Distograph and obtain sharp pictures."

"A simplified method of developing your own films. The ——— Tank. Ask for demonstration."

"For speed pictures—a Reflex. You see the image up to the moment of exposure."

"Use a colour filter when photographing clouds and flowers these days."

"Knowledge is power. Come in and see our selection of photographic publications."

At the Beach.

The Kern Music Co., Providence, R.I., desired to make camera sales to folks going away to the beach over week-ends and on holidays. As a window display feature, they introduced the wax model of an attractive young woman, attired in a cerise one-piece bathing suit. A green cape partly draped one of her shoulders. The floor underneath was carpeted with artificial grass (beach sand and pebbles would have been more appropriate), with cameras and films laid about the same.

Another Beach Setting.

The Robey-French Co., Boston, Mass., covered their window floor with green crêpe paper, with a square plot at the centre rear covered to a depth of two inches with beach sand. There was a bathing girl kewpie doll lying on the sands, with her head protected from the blazing sun by a miniature parasol. Over the other side of the sand was a second bathing girl kewpie, with a camera in her hands, focussed at the first kewpie. Little bits of atmosphere were provided by a beach pail and spade. The space elsewhere in the display was given over to cameras.

Concentrating on One Camera.

Wheeler's Claremont, New Hampshire, concentrated their window display on the 2C Kodak. Their window floor was draped with white crêpe paper, with samples of work done on the camera exhibited here and there. One of the cameras was displayed on a mound at the rear centre. Across the rear was a three-panelled screen in light green, with a card on the middle of each panel. These cards bore such messages as those given below :—

"Wise men who travel carry a Kodak."

"Kodak as you go."

"For the out-of-door days—Kodak."

A Neat Display.

The Almer Coe Co., Chicago, Ill., arranged cameras on white enamel plates, with an occasional camera placed on a raised glass pedestal. On a raised plate at the front centre were several small articles needed by photographers. Albums, opened to show what the photographs were like, were leaned against the background.

The window down by the glass sloped up, and on this wooden base camera pictures of local interest were placed.

The Camera Bellows.

The Denver Photo Co., Denver, Colo., achieved the effect of camera bellows in an ingenious manner. Cheese cloth was stretched out from front to rear, the smallest portion being at the rear, where the bellows met almost at a common point. Here the lenses of a camera were placed.

Verifying that Fish Story

The North-Western Photo Supply Co., Seattle, Wash., adorned the background with a large framed picture of the lake and mountains. The opposite rear side was occupied by a coloured picture of fishing tackle, with fish surrounding the basket. A bunch of real fishing tackle was placed on the floor at the centre, with a card that advised :—

"Let your camera verify your fish story."

A Daily Reminder.

Cunningham's, Detroit, Mich., had a large sign over their camera counter with space left for the insertion of a small white card, which is changed daily. On the particular day that I entered the store the sign announced :—

"Sunday, September 5.
Buy that Camera to-day."

Clever Way of Using Prints.

The Seattle Film Shop, Seattle, Wash., was responsible for a simple but effective glass-case display. The word "Kodak" was spelled out on the showcase floor with the aid of camera snapshots. The prints were arranged over a black crêpe covering, and ran down the case in a zig-zag angle.

An Elaborate Showcase Display.

The Broadway Department Store, Los Angeles, Calif., covered the bottom of their large counter showcase with a raffia rug. Green foliage covered the rear and sides of the showcase, with a spotlight hidden at the top right rear. This threw a light that resembled sunlight—a great assistance in a dark store. Inside the showcase was the wax figure of a little girl doll in white muslin, sitting on a kiddie car at the centre front with the "sunlight" on her face. At the opposite side was another girl doll, this time in blue muslin. She was manipulating a tripod camera. At her feet was an empty film pack. ERNEST A. DENCH.

ADVERTISING FOR PHOTOGRAPHERS.

A Talk by a photographer of Kansas City, U.S.A., before the Cameracraftsmen of that city at a recent meeting.—Reprinted from "Abel's Photographic Weekly."

Business is like a machine—it will not run of its own accord, but must be driven by some vital force. What steam is to the locomotive, electricity to the motor—advertising is to business.

The mighty force of advertising is creating and keeping alive all our business institutions. Every successful business is backed by advertising. Every business can widen its commercial horizon and swell its profits by advertising.

Also, business is like a plant, it must be nourished or it will die. What water and care are to the plant, advertising and attention are to business. If your business is sick or run down, it needs nourishment—a tonic—give it more advertising.

All advertising is not good advertising, any more than all eggs are good eggs. I have wasted money on advertising, because I did not know the good from the bad. I am going to tell you what experience has taught me about advertising.

Photography is not only a profession but a business. Every man, woman and child in your community is a prospective customer. Rich men, poor men, from bank presidents to labourers; society women to waitresses, boys and girls, even babies. Go after this business with advertising.

I believe that good work is the best advertising. Every good portrait the photographer turns out is for him a lasting advertisement. A satisfied customer will return to your studio, or send some member of his family, or friend, or speak a good word for you.

I believe a street display is good advertising. I have three street entrances to my studio; two on one street and one on another street. At these entrances I have large brass show cases and I keep them filled with fresh, new pictures. In the lower hallways I have other cases filled with pictures, and at all the entrances, on each step on the stairs, I have the words in large display type, "MOORE'S STUDIO." In the upper halls I have other cases filled with pictures, and the rooms of my studio are filled with specimens of my work.

I have a large electric display sign which projects far out over the sidewalk. This sign is so large that it can be read for a good distance in either direction. Passers-by are continually stopping to look at my display pictures, and it would be hard for anyone passing on either side of the street to miss seeing my signs and pictures.

I believe in newspaper advertising. The local newspaper carries my advertisement all the year round, at least once a week, often three or four times a week. In my newspaper advertisements I use pictures of men, women and children—a different picture each time. These pictures are reproduced by an artist at the newspaper office—with the wording "Photo by Henry Moore," so that no one can look at the picture without seeing the name of the photographer. This makes the picture in itself, an advertisement. The pictures are two columns wide, and the little write-up I put under the picture is usually two inches long.

Under a child's picture I make a little statement referring to the value of the child's photograph to its parents, and under the picture of a grown person I write something concerning the appreciation that always follows such a gift to the children, relatives or friends. Under the picture of an elderly person, I have found it profitable to advertise that I would make one photograph free of charge—of any man or woman who had reached the age of sixty years—offering additional copies at the regular price. And as an excuse for making this offer, I mention the fact that old people seldom realise what their portraits mean to their children, or their friends. The people who accept my offer always get my best work, and they seldom order less than three additional copies, and very often a dozen copies.

A personal letter, well written and signed by the photographer, commands the favourable attention of your prospective customer. The letter that is friendly and dignified in appearance, will be read and remembered. Money spent in this kind of advertising is not wasted. I believe that a circular letter, printed on a machine, with a rubber stamp and mailed at the cheapest rate, is a waste of time and money.

I dictate to my typist a form letter that would apply to a certain class of customer. She writes a separate letter to each customer, repeating in the body of the letter the name of the prospect. This adds a personal touch to the letter, and is proof that the letter is typewritten—not printed. Each letter is signed with pen and ink. I employ three typists and keep them going writing individual letters. I could have these letters printed, and names and addresses filled in—saving me person to do the work, but the letters would not show the personal touch, would lack force and real advertising value, and the results would not be satisfactory.

Nowadays most people accept you at your own valuation. It's the same with a piece of postal matter—the value you place on it is shown by the way it's written and addressed. You must make your customer understand that you want his business and are willing to spend time and money to get it. Your customers are apt to figure that if the letter you send them is not worth dictating, and signing, and sending out with a letter-post stamp, it's not worth reading. I have tried both methods and experience has taught me that the more care I take in advertising the better the results. I do not believe in long letters. A short letter tempts even the busiest business man to read it. A long letter, unless of vital importance, is often laid aside to be read later, or tossed into the waste basket.

I do not believe in hand bills, or advertising matter distributed

from house to house. This method of advertising places the mark of cheapness and unimportance on it. I don't care how nicely the advertising is prepared. If you distribute your advertising as if it were of little or no importance, it will be accepted at the low valuation you place on it, but if you post it as a letter it ranks in importance with the regular correspondence, and is given the careful attention it deserves.

You can prepare your mailing list from the telephone book, selecting the names and addresses of the people whose patronage you desire. There are other ways of securing suitable names.

It is required under the law that each birth be reported and recorded at the office of the Board of Health. I have an arrangement with a clerk in that office whereby I am furnished with the name and address of the parents in the event of a birth in their home. For this service I pay two cents for each name. I write the parents a personal letter expressing my good wishes for the baby, and hope that I may have the pleasure of making its first picture.

Also, I have an arrangement with a clerk in the office of the Recorder of Marriages. Very often, within five minutes after the notice of a marriage has been given I have the home address of the bride and groom. Sometimes, if they live out of the city, my letter is waiting for them when they arrive at their home. The letter conveys my best wishes, and an invitation to come to my studio for a sitting.

I have been fairly successful at my profession and in my business, and there are two reasons for my success. First, because I have always tried to make good pictures I have never been fully satisfied with a picture, but always tried to improve on my work. Second, I believe in good advertising, and have patiently and persistently kept at it.

HENRY MOORE.

THE GLOSS CHARACTERISTICS OF PHOTOGRAPHIC PAPERS.

(A Communication from the Research Laboratory of the Eastman Kodak Company.)

IN a systematic study of the characteristics of photographic papers a consideration of the surface quality is of great importance. The most important factors required in the specification of surface quality are colour, texture, and gloss. The colour can be measured by the employment of suitable colourimetric methods, the results being most conveniently specified by stating the diffuse reflecting power, wave-length of the dominant hue, and the saturation. These three factors, which are necessary for the specification of colour, completely define from the subjective standpoint the quality and intensity of the light reflected from the surface.

The word "texture" is used in referring to the topography of the surface. Thus far no simple numerical method of expressing quantitatively the texture of the paper has been developed. At the present time the texture is best studied by examining the surface under a microscope. A magnification of from 10 to 20 diameters has been found to be most suitable for this work. Photomicrographs made with a fixed magnification and under certain specified and constant conditions of illumination are found useful in case a permanent record of the texture characteristics is required.

The third factor mentioned, that is, gloss, is dependent upon the geometrical distribution of the light reflected from the surface under consideration.

In general it may be said that of the light reflected from the surface of such materials a part is diffusely reflected while the remainder is reflected specularly, that is, in accordance with the law that the angle of reflection is equal to the angle of incidence. Considering surfaces in general, it is found that an infinite number of variations in the ratio of specular to diffusely reflected light exists, the scale being theoretically limited at one end by a surface which reflects all of the incident light, according to the law that the angle of incidence is equal to the angle of reflection, and at the other by a surface which reflects light equally in all directions regardless of the angle of incident illumination. The characteristic of the surface referred to by the words "glossy" or "glossiness" is dependent upon the relation existing between the light which is diffusely and regularly reflected from the surface, and it is with the measurement and numerical specification of this factor that this paper deals. It is customary, at the present time, to designate the gloss factor of a photographic paper by the use of such descriptive words or terms as "matt," "semi-matt," "velvet," "glossy," etc. It is evident that the use of the words can only approximately specify the gloss quality, and it is very desirable for the sake of more precise designation to develop a method for the numerical specification of this quality.

The problem of mixed specular and diffuse reflection has been treated at considerable length in the reports of the Committee on Glare[1] of the Illuminating Engineering Society. In these reports Dr. P. G. Nutting, who was chairman of the committee at that time, presented a very complete mathematical treatment of the problem and proposed as a logical specification of gloss the ratio of the specular reflecting power to that of diffuse reflecting power, the illumination being incident normally and the illuminating source of such dimensions as to subtend .01 steradian at the surface. In one of the reports considerable data relating to the gloss of various print papers and to some photographic papers are given.

Taking advantage of the fact that in the case of mixed specular and diffuse reflection the regularly reflected component is almost completely polarised under certain conditions, Professor L. R. Ingersoll[2] has developed a polarisation method of measuring the gloss factor. In his instrument the conditions of illumination both as regards angle and size of source are chosen arbitrarily. Under these conditions, the ratio between the intensity of the regularly and diffusely reflected components is measured by some type of polarisation photometer such as the Martins photometer or the Pickering polarimeter. This instrument provides, therefore, an arbitrary scale upon which the gloss values may be expressed.

The term "gloss" is used as descriptive of the subjective impression received when observing a surface from which light is reflected, and there is little doubt that the degree of glossiness is dependent upon the contrast between the brightness of those portions of the surface which are seen by diffusely reflected light and those which are seen by regularly reflected light. In other words, gloss must be a function of the brightness contrast existing between the more or less clearly defined specular images of light-sources having relatively small angular dimensions and the contiguous portions of the surface which owe their brightness to diffusely reflected light. It seems logical, therefore, that the absolute scale of gloss can be established only by measuring this brightness contrast under certain specified conditions of illumination and observation.

The Gonio-Photometer.

Before deciding upon the conditions under which such measurements were to be made, it seemed desirable to measure the distribution of light reflected from the surface under consideration for various conditions of illumination. This involved the determination of the reflection characteristics of the surfaces for all angles of observations, and under certain specified conditions of illumination.

For this purpose a special instrument termed, for convenience, a "gonio-photometer" was designed and constructed. A diagram showing the essential parts of this instrument is shown in fig. 1.

A heavy cast-iron base, A, supports the arm B, at the end of which is carried the photometric apparatus. In order that the observer and the photometric equipment might not interfere with the illumination of the sample at angles approaching closely to the normal, the axis of observation was bent at right angles by use of the total-reflection prism C. A portable photometer of the illuminometer type was mounted at D; and the small lens E, placed imme-

1. Trans. "I.E.S.," vol. 10, 1915, p. 353, 379 and 388.

2. "J. Opt. Soc. Amer.," May, 1921, p. 213.

diately in front of this photometer, permitted the formation of an image of the surface under examination in the plane of the photometer cube. In case the texture of the surface was such as to interfere with precise photometric settings, this lens could be displaced by amounts sufficient to eliminate the troublesome surface texture. A rigid bearing E supported by the base casting carries a movable arm G, on one end of which is mounted the lamp-house H, while at the other end a counterpoise weight I is placed. A holder is pro-

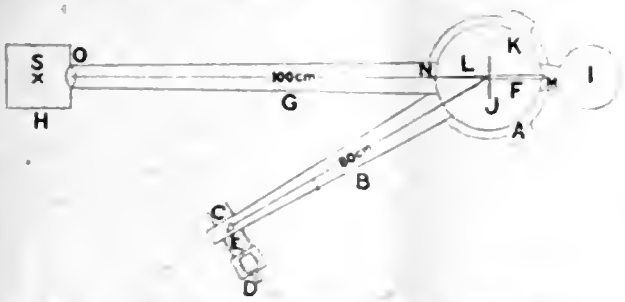

Fig. 1.—Diagram showing essential parts of instrument.

vided for the sample at J; this is so mounted that it holds the surface of the samples being examined in the plane passing through the axis of rotation of the arm G. The circular scale plate K is mounted in a fixed position relative to base A. A pointer attached to the sample holder indicates the angle on the divided circle. By means of a pin M, the sample holder can be connected rigidly with the moving arm G, so that the plane of the sample will remain perpendicular to the incident illumination for all positions, and as the arm G is rotated the angle of observation alone varies. This provides for the measurement of the surface brightness at various angles of observation and fixed direction of illumination. By removing the pin M and clamping the sample holder to the base, A, the arm G moves independently of the sample, and observations of brightness at a fixed angle of observation, but with a variable angle of incidence, can be made. In the front of the lamp-house is mounted a lens O of such focal length that the source S falls at its focus. Under such conditions the light incident on the sample is approximately parallel. The dimensions of importance are as indicated in the figure. It is also so arranged that the lens O can be removed, and in its place substituted a disc of diffusing material, such as ground pot opal glass.

The dimensions are so adjusted that the effective area of this diffusing material is just sufficient to subtend an angle of .01 steradians at the surface of the sample under examination. A 500-watt Mazda C lamp of the concentrated filament type was used as a source for illuminating the samples. A photograph of the apparatus is shown in fig. 2. The voltage was precisely controlled in

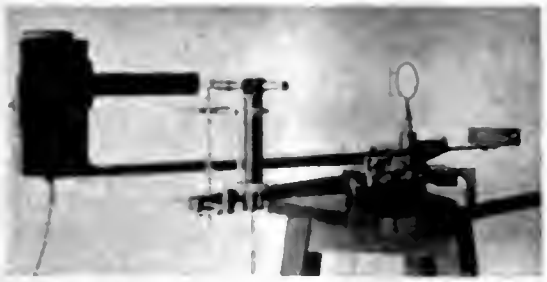

Fig. 2.—Photograph of apparatus.

order to eliminate variations in brightness due to fluctuations in the line voltage. Complete distribution curves of the light reflected were obtained from a series of samples, with the illumination incident on the sample at various angles.

From a consideration of the way in which the average observer adjusts a photograph, which he is examining with respect to the line of sight and the direction of its illumination, it appears that the most favourable and comfortable conditions are obtained when the line of sight is normal to the surface of the print and the illumination incident at an angle of approximately 45 deg. from the normal. Such an adjustment of conditions prevents the observer from being annoyed by specular reflection from the surface in case such exists. In a previous paper[3] this same condition of illumination and observation was adopted as being the most suitable under which to measure the photographic densities of prints and of sensitometric test strips used in the determination of sensitometric constants of such materials. These conditions were chosen as representing most closely the average conditions of illumination under which photographic prints are observed.

From a consideration of the distribution curves and also from a consideration of the way in which a photographic print is usually observed, it was decided that a comparison of the brightness of the surface when viewed normally, and at the angle of specular reflection with the illumination incident at an angle of 45 deg. from the normal, would give a determination of gloss most nearly in accord with the commonly observed value of that factor.

The diagram in fig. 3 illustrates the conditions of illumination and observation which were adopted for the measurement of gloss. The line *MN* represents the plane of the sample under consideration. This is illuminated by a beam of parallel light incident in the direction *AO*. A brightness measurement of the surface is then made in the direction represented by the line *BO*, and this brightness will be designated by the symbol *Bd*. A second brightness determination is made in the direction *CO*, and this value is designated by the symbol *Bs*. Let the curve *KLPR* represent the complete brightness distribution curve of the sample under consideration. It is evident from the shape of this curve that the reflection from this sample is of a mixed specular and diffuse type. It is evident that the value of *Bd* is a measure of the diffuse reflecting power of the sample while the value of *Bs* is a measure

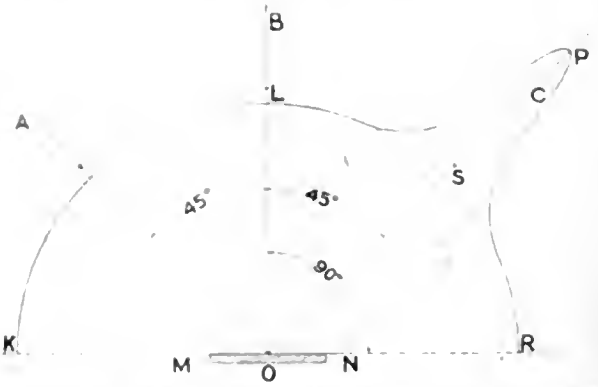

Fig. 3.—Illumination and observation adopted for measurement of gloss.

of the specular plus the diffuse reflecting power of the sample. The brightness (*Bs*) due to specular reflection may therefore be obtained by subtracting *Bd* from *Bs*. That is, $B_s = B_s - B_d$. As previously stated, gloss is a function of the brightness contrast between the more or less clearly defined images of light-sources having fairly small angular dimensions and the contiguous portions of the surfaces which are visible by virtue of light diffusely reflected from them. It is very evident from a consideration of the values obtained in practice that the subjective impression of gloss, or perhaps, more properly speaking, of "glossiness," is not directly proportional to the contrast value. This contrast may, however, be taken as an adequate measure of the physical stimulus producing the sensation of glossiness. It may be convenient to use different terms as representative of the physical aspect or stimulus and the subjective aspect or sensation. Such a procedure will be analogous to the use of "brightness" and "brilliance" in referring to the intensity factor of radiation and the subjective sensation resulting from its action on the retina. In this case the term brightness is used as descriptive of the physical or objective aspect of the stimulus, while the term brilliance is used in reference to the resulting sensation.

It is proposed, therefore, to adopt the term "gloss" as descriptive of the stimulus, while the term "glossiness" will be used in referring to the subjective sensation produced. The experimental results given in the paper relate almost entirely to the measurement of gloss, and while some indication has been obtained as to the relation existing between the stimulus, that is gloss, and the

3. "B.J.," 1921, 9, 22, 38; and "Phot. J.," 1914, 54, p. 342.

resulting sensation, glossiness, the data available are entirely inadequate for the formulation of a definite physical relation between the stimulus and the sensation. The distribution curve of a surface having zero gloss is represented by the curve *KLSR* and for such a case $Bd = Ba$ and $Bs = 0$. Gloss (G) may therefore be defined by the equation

$$G = \frac{Bs}{Bd} = \frac{Ba}{Bd} - \frac{Bd}{Bd} = \frac{Ba}{Bd} - 1 .$$

On the basis of this definition, the scale of gloss extends from zero, for a surface which reflects light equally in other directions, that is, one obeying Lambert's cosine law, to infinity for the surface from which the reflection is entirely specular.

It will be recalled that in the reports of the Committee on Glare (loc. cit.) it was recommended that a source of such dimensions as to subtend .01 steradian at the sample be used in the measurement of gloss. The practical objection to this procedure is that under such conditions it is difficult to obtain illumination on the sample sufficiently high to give a field brightness in the photometer which will result in high precision and absence of fatigue in reading the instrument. In order to determine the magnitude of the difference in the measured gloss values when using this type of illumination and that obtained by using a beam of parallel light, a series of measurements were made. A group of samples varying from very high to very low gloss were chosen, and the gloss values of the group determined with both types of illumination. The results, which will be given in detail later, show that when illuminated with a collimated beam the gloss values ranged from .43 to 24.0, while with a source subtending .01 steradian the values varied from .36 to 12.4. This indicates that the use of collimated illumination provides a more extended gloss scale, thus permitting the measurement of smaller differences in gloss than could be measured when the source subtends a larger angle. For these reasons it was considered advisable to specify that gloss measurements be made with the sample illuminated by parallel light. While it is quite possible to make gloss determinations by using the goniophotometer, this requires two individual photometric readings, one made with the direction of observation normal to the surface and one at 45 deg. from the normal. Although this method is satisfactory, it is not suitable where a very large number of samples are to be examined, nor does it afford the precision required for the comparison of samples differing but little in gloss.

The Gloss Meter.

The best conditions of illumination and observation having been determined from an analysis of the results obtained with the goniophotometer, an instrument for the direct measurement of gloss was designed and constructed. A schematic diagram of this instrument is shown in fig. 4.

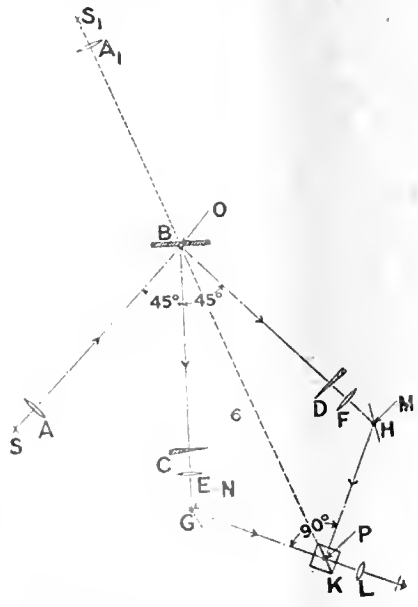

Fig. 4.—Schematic diagram of instrument.

The light-source is placed at the focal point of lens A, which is a well corrected telescopic objective. The light-source used is a tungsten lamp having a highly concentrated filament, thus approaching as closely as possible to a point source. The collimating beam is incident upon the sample B at an angle of 45 deg. from the normal. The lenses E and F placed respectively on the normal to the surface and on the line at 45 deg. from the normal form images of the sample B in the photometer cube K. The focal length of these lenses and the distances are such that the images are of unit magnification. The mirrors G and H properly placed serve to reflect the beams of light as indicated so that they intersect each other at an angle of 90 deg. in the photometer cube. The photometer field is viewed through the lens L with an eyepiece of the type commonly used for such work. The brightness of the two images formed by the light leaving the surface normally and that formed by the light leaving at an angle of 45 deg. can be varied by means of the neutral tint wedges C and D. The zero of the instrument is set by replacing the sample by a piece of pot opal glass so placed that the line *OP* which bisects the angle *NOM* is normal to its surface. This is illuminated by swinging the light-source with its collimating lens into the illuminated normally with a beam of parallel light, and images of this surface are formed in the photometer cube by light which leaves the surface at equal angles on the opposite sides of the normal to the surface. With the scale which is attached to the neutral wedge D set at zero, a photometric balance is made by adjusting the position of the neutral tint wedge C; this adjustment having been made, the light-source is returned to the position for the illumination of the sample as designated by the letters S and A. The sample to be examined is then placed in position B, and a photometric balance made by moving the neutral tint wedge D. This gives a direct measurement of the relative brightness of the surface as viewed normally and at the angle of specular reflection. The scale carried by the wedge D may be calibrated either to read the ratio of these two brightnesses or, if desired, to read directly in gloss values. In the case of some surfaces having a marked texture, it may be found difficult to make precise photometric settings when the image is focussed in the photometric cube. By displacing slightly the lenses E and F the sharp focus can be destroyed and this difficulty overcome.

FORTHCOMING EXHIBITIONS.

April 4 to 19.—Royal Photographic Society. Prints by Dr. H. B. Goodwin. Open daily from 11 a.m. to 5 p.m. 35, Russell Square, London, W.C.2.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography."

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 27 to April 1 :—

ENLARGING APPARATUS.—No. 8,951. Photographic enlarging apparatus. E. A. Green.

SHUTTER MECHANISM.—No. 9,188. Shutter mechanism for photographic cameras. T. Litchfield.

CAMERAS.—No. 9,191. Photographic cameras. T. Litchfield.

TRIPODS.—No. 9,030. Tripods, etc., collapsible stands. H. Ranson.

FILMS.—No. 9,457. Securing strip of photographic film in flat coil for treatment by liquid. Correxmüvek Filmipari Gepgyar C. Lazlo.

SURVEYING.—No. 8,919 Photographic surveying. J. W. Gordon.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SILVER-IRON SENSITISERS.—No. 175,317.—(August 20, 1920). In Patents 9,993/1902 and 9,855/1907, were described photographic emulsions containing silver phosphate in the insoluble form. According to the present invention silver phosphate is used in dissolved form, *i.e.*, paper is sensitised by the use of a solution of silver phosphate and the ferric salt of an organic acid, and may be developed by the alkali salt of an organic acid.

Such solutions of silver phosphate may be prepared by treating either the orthophosphate, meta-phosphate, or pyro-phosphate of silver, especially when freshly prepared, with a sufficient quantity of ferric salts of organic acids, more particularly ferric oxalate or citrate which must be free from the corresponding ferrous salt. The ortho-phosphate readily dissolves in a solution of such salt at ordinary temperature, but the pyro-phosphate and meta-phosphate require to be heated to about 50 to 60 deg. C.; possibly the pyro or meta-salts are converted into the ortho-phosphate prior to or during solution. In any case the solutions so obtained appear to represent either true or colloidal solutions of silver phosphate.

The silver phosphate, preferably in the freshly prepared form, *e.g.*, the product of double decomposition, is then treated with a solution of the ferric salt of an organic acid, preferably ferric oxalate which appears to be the most satisfactory, when a solution is obtained which is found to be capable of preservation in the dark for prolonged periods while still remaining photographically perfect.

Such solutions under whatever conditions they may have been prepared appeared always to possess the same speed and gradation and to produce the same tone provided the nature and the proportions of the components are unchanged.

The sensitising solution so obtained may be treated to increase its viscosity, *e.g.*, by mixing the finished solution with suitable colloids such as solutions of gelatine, gum-acacia, or the like, but these colloids must not be added during the process of preparing the silver phosphate. Albumen must not be mixed with the solution as it is coagulated thereby, and if it is necessary to employ albumen in the manufacture of the paper, the materials to be sensitised must be coated first with plain albumen and dried before sensitising by the solution.

After exposure, the print is developed by treatment with an alkali salt of an organic acid preferably the alkali salt of the acid present in the ferric salt.

It appears that when sensitised material prepared from the above solution is exposed to actinic light, two different photochemical actions are produced, viz., the ferric salt is reduced to ferrous salt in proportion to the amount of light received and the silver phosphate, which possesses all the properties required for the production of a perfect image, is, at the same time, affected also in proportion to the amount of light received. Now when the reaction has taken place, the ferrous compound produced will act as a developer for the silver compound in presence of the alkali salts of the organic acid, and it will be seen that the amount of the developer is automatically proportionate to the amount of exposure which has taken place.

The invention is illustrated by the following examples; the operation should be carried out in yellow light or taking other precautions to exclude actinic light.

A.—SENSITISER WITHOUT COLLOIDS.

(1) Place 30 gms. of ferric oxalate (stales) free from proto-salt in a suitable vessel, add 100 ccs. of distilled water, stand the whole in a boiling water bath, and, stirring or shaking from the start, leave it there till all has dissolved. Remove from water bath, let cool to ordinary temperature and filter through pure paper.

(2) Into a glazed porcelain or earthenware dish (mortar) place:

4.8 gms. silver nitrate.

2.3 gms. sodium phosphate ($Na_2HPO_4 . 12H_2O$).

70.0 ccs. distilled water of ordinary temperature.

Rub up with pestle until the salts have dissolved, and the yellow silver phosphate has settled out.

Then add to the contents of the dish, 70.0 ccs. of the iron peroxalate solution 1 at ordinary temperature and rub up with pestle till the silver phosphate has dissolved, add

(3) 3.0 gms. of citric acid (powdered crystals, free from lead) rub up till the citric acid has dissolved, filter through pure paper. Preserve in glass-stoppered bottles of deep yellow glass in the dark.

B.—SENSITISER WITH A COLLOID (GELATINE).

If an addition, *e.g.*, of gelatine be required, proceed as follows: Make up the filtered sensitiser exactly as described above, but instead of the 70 ccs. of distilled water prescribed for preparing the silver phosphate (No. 2 of Example A), use only 30 ccs. In the 40 ccs. of distilled water remaining, soak and afterwards dissolve at about 30 to 40 deg. C. the desired amount, say 4 gms., of medium photographic gelatine, add the filtered sensitiser to the warm gelatine solution, well agitating during addition, and finally filter the mixture through absorbent cotton or other suitable material. The concentration of the gelatine sensitiser will then be exactly the same as that of the sensitiser without gelatine described above.

This gelatine sensitiser remains liquid at temperatures above 10 deg. C. It is evident that sensitisers with any other suitable colloid may be prepared by simply substituting the gelatine of the above example by such colloid.—York Alexander Ferdinand Schwartz, 14, Park Parade, Harlesden, N.W.

STEREOSCOPIC PROJECTION.—No. 175,930 (June 21, 1921). The invention relates to the analyser for viewing projected stereoscopic pictures.

It is, of course, necessary that the movements of the shutter in such analysers shall synchronise with the appearance of the views on the screen, and this is effected by pneumatic means, in such manner that the movement of the analyser shutter is controlled by the movement of the lantern shutter or in the case of a cinematograph projector by a moving part thereof, so that the left eye sees one picture and the right eye sees the complementary picture immediately afterwards. These two pictures being coalesced, by the persistence of vision, produce on the retina of the eye the impression of a single picture in stereoscopic relief.

The analyser is conveniently made in a form somewhat resembling a pair of opera glasses mounted on a frame and supported in the centre by a handle, the two eyeholes being provided with, or being without, lenses and a shutter or shutters operated to alternately cover these openings.

Fig. 1 shows somewhat diagrammatically the construction of an analyser as worked by pneumatic means alone, and fig. 2 shows part of an analyser constructed to work by pneumatic means in conjunction with electricity.

The shutter *a*, fig. 1 is attached to a rod a^1, suitably pivoted at *b*, so that it can be reciprocated quickly back and forth over the eye openings *c* and c^1 on frame *d*, in order to alternately uncover and cover these two openings, the shutter device being adapted to be reciprocated by pneumatic means.

One way in which this can be effected is by providing the instrument with a small conical, cylindrical or otherwise shaped box *e*, containing a diaphragm *f* of thin rubber. The top part of this box, also the diaphragm, would be open, in order to give free access to the atmospheric pressure, also to allow the rod *g* to pass from the centre of the diaphragm, where it would be attached to the crank and pin *h*, for the purpose of connection. The lower part of the box beneath the diaphragm would be closed, except that a metal tube *i* would pass from the bottom of the box through the handle *j*, so that a rubber tube *l*, preferably armoured, could be easily attached. This rubber tube would lead to a pneumatic impulse-generating device, through

which, in conjunction with valves, periodic impulses would be transmitted to actuate the diaphragm and by suitable rod connections and gearing, also the shutter of the analyser in synchronism with the pictures.

An electro magnet *m*, as shown in fig. 2, may be attached to the analyser, which would be so placed that it could act upon armature *n* when the electric current is in circuit, which armature would also act as a valve and be a part of the valve shown at n^1. Immediately this valve was opened, the air would pass through inlet *o* and thence through *p* and tube *q* to the diaphragm box *e* and force diaphragm *f* upwards, and by means of suitable connections the shutter would move, say to the right, and immediately the electric circuit was broken the spring *r* would pull the armature back again and so close the portion of the valve *n* and at the same time open the portion of the valve at n^1, consequently letting the air contained in the diaphragm

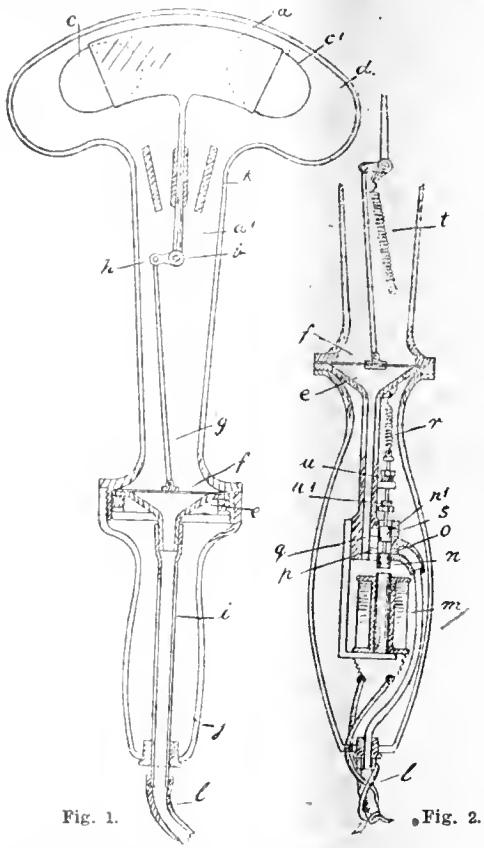

Fig. 1. Fig. 2.

box escape through the exhaust *s*. The air pressure being thus cut off, the diaphragm with the assistance of the spring *t* would drop, or be forced down again, and the shutter would be pulled to the left.

Two rubber stops *u* and u^1 (fig. 2) are employed to prevent the poles of the electro magnet and armature touching and the arrangement and manner in which the air tube and wire leads pass out through the handle of the analyser is shown at *l* fig. 2.

The electric current for exciting the magnet and attracting the armature would be controlled by means of a commutator, or make and break device which would be attached to some suitable working part of the projector, or in case of still life projection to the shaft carrying the revolving shutter placed before the double lantern. The electric leads could run along the connecting tubes, and so reach the analyser.

In the case of an exhibition of sterenscopic pictures more than one analyser may be used at the same time, it only being required to make the necessary tube or wire connections so that the movements of the diaphragms (or the diaphragms and armatures) of the individual analysers are all effected and controlled from the lantern or projecting apparatus.—Arthur Norton Wright, 26, Court Road, West Norwood, London, S.E.

The following complete specifications are open to public inspection before acceptance :—

Photographic Machine.—No. 177,537. Photographic machine. E. Zoffinger.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Kodak (Design).—No. 420,930. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials. November 25, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

Desium.—No. 414,023. Light filters for cinematograph projectors. David Kennedy, 215, Selhurst Road, South Norwood, London, S.E.25, manufacturer.

N. G. (Device).—No. 412,035. Philosophical instruments, scientific instruments, and apparatus for useful purposes; instruments and apparatus for teaching. Nitsche & Gunther Optische Werke, 4-5, Dunckerstrasse, Rathenow, Germany, manufacturers of scientific and optical instruments.

Teddy.—No. 415,931. Photographic cameras. Edmond Francis Stratton, 1, Cedar Street, South Norwalk, State of Connecticut, United States of America, manufacturer.

Wellington Speedy (Design).—No. 412,492. Photographic dry plates. Wellington & Ward, The Elms, Shenley Road, Boreham Wood, Elstree, Hertfordshire, manufacturers.

Zenith.—No. 417,425. Chemical substances used in photography, photographic plates and photographic films included in Class 1. Ilford, Ltd., Britannia Works, Roden Street, Ilford, Essex, manufacturers of photographic plates, paper and films.

Bayrapid.—No. 417,364. Chemical preparations for photographic purposes. Farbenfabriken vorm. Friedr. Bayer & Co., Leverkusen, near Cologne-on-the-Rhine, Germany, manufacturers.

CROYDON CAMERA CLUB.

Quite one of the most enjoyable evenings of the session was afforded by Mr. G. H. Gardner with a lecture on "Photography and Crime," a two-sided subject, he said, both aspects doubtless being, more or less, familiar to his fellow members.

Photography was largely employed by a certain class of malefactors who were not necessarily of the pictorialist order, and the same craft rendered invaluable service in the detection of crimes and their perpetrators. As methods improved so the habitual criminals endeavoured to defeat them—a sort of "gun *versus*

armour-plate" contest, quite a nice game played slowly. Consequently he proposed to refrain from describing any procedures a knowledge of which might be helpful to the enemies of society.

Of considerable utility in training the powers of observation were portraits, which were largely used in the education of recruits to the police force. Although it might not seem so, really accurate descriptions from memory of facial characteristics were very difficult.

Following came a sketch of the photographic department at Scotland Yard, evidently thoroughly up-to-date and complete in all respects, and a brief allusion to the many scientific and highly ingenious methods in use. Next, a full consideration of the finger-print method of identification, and the really wonderful system by which finger-prints of suspected persons can be quickly identified with their counterparts if in stock. The lecturer then appropriately asked the President thus to record himself. "Don't do it unless you want to be on the file at the Yard," excitedly warned the "office boy." "The records are probably there now, along with yours," sadly observed Mr. Gardner.

In the discussion Mr. Ackroyd inquired what was the lecturer's opinion of "Sherlock Holmes"; whether any steps had been taken by Scotland Yard to disguise policemen's boots; and if it were not true that the guardians of law and order were under considerable obligations to "narks."

Mr. Gardner replied that as the originator of the Sherlock Holmes happened to be a personal friend, he would content himself by saying that this remarkable character in fiction resembled an ideal photograph—one heard of, but never seen. Policemen now bought their own boots. "Narks," certainly, were very useful at times.

Mr. Walker, referring to a chart issued by the Yard during the war showing the probabilities of future air raids day by day, asked if copies were publicly distributed. "They were sent to all police stations," answered the lecturer. "I never saw one," indignantly exclaimed Mr. Walker.

During the evening a pleasant letter of partial farewell from Mr. Catharine was read, expressing gratitude for the happy times he had spent in the club, and the useful information acquired on many subjects, including photography. Escaping once a week from the depressing artificiality which pervaded Suburbia, to a community where a man could call another a blithering ass in a spirit of pure friendship, had been a welcome relief. It is understood that Mr. Catharine has joined the R.P.S. as the London society best suited to his needs.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on Monday, April 3. Present: Mrs. MacKay, Mr. J. Campbell Harper, Mr. Norman Thomson, Mr. W. B. Hislop, Mr. E. D. Young, Mr. Ferguson, Mr. Aikman and Mr. Swan Watson. Mr. J. Campbell Harper, the President, in the chair.

Apologies for absence were intimated from Mr. J. B. Johnston, Mr. P. S. Moffat and Mr. George Balmain.

The President, one of the visiting committee to Mr. Hislop's Class on Optics and Practical Chemistry at Boroughmuirhead School, stated that after his visit on the 7th ult. he should have liked very much to have been present at every one of Mr. Hislop's lectures. He considered that Mr. Hislop's methods of teaching were of a very high standard, and his ability and business capacity enabled him to deal with the subject in the most effective manner possible. The students appeared to be exceedingly interested, and altogether the class impressed him as being well conducted and most instructive. Mr. Swan Watson, another member of the committee, stated he had only unqualified praise to speak of the lecturer, whose lectures came to him as a great revelation. He had attended a number of the lectures, and throughout the instruction had been intensely interesting, lucid and of a very high standard. He thought that the Society owed Mr. Hislop a real debt of gratitude for the time and trouble which he devoted towards these lectures. Mr. Hislop stated that owing to lack of time and pressure of other business he regretted he could not undertake the tuition of the class for next session. He thought it might be an excellent opportunity for a professional photographer to take it up. He further stated that he understood the Heriot-Watt College authorities had serious intentions of re-starting classes for process engravers next session, in which event he suggested that the Society should endeavour to get the class for optics and chemistry conjoined with these as an elementary class. He personally preferred the classes run by the Heriot-Watt to those of the Education Authority, as the student who attended the former got every consideration, and the Heriot-Watt College had more appliances and working utensils for demonstrating lectures. Mr. Hislop's resignation was received with much regret, and he was at once asked to re-consider his decision. Mr. Hislop, in view of the unanimous and hearty feeling of the meeting, undertook to re-consider the whole matter and write a report for the next meeting.

Mr. E. D. Young stated that he had been informed by the Secretary of the College of Art that any apprentices who wished to attend the classes conducted by Mr. Hislop at Boroughmuirhead School and by him at the College of Art on applying in June next to Mr. Arthur Butler, Edinburgh Educational Trust, Castle Terrace, Edinburgh, would have their fees paid, and also a certain sum would be allowed to the College for each apprentice for working utensils for the classes.

It was unanimously agreed to grant a donation of £1 1s. towards the prize fund of the retouching class at the College of Art, and the Secretary was authorised to pay the same.

The Secretary read a letter from Mr. T. Black, Secretary of the Glasgow and District Professional Photographers' Golf Club, addressed to Mr. George Balmain, suggesting May 12, at Glasgow, for the golf match between the Societies. It was agreed to accept the date mentioned.

The President and Mr. E. D. Young reported that on March 16 last they went as a deputation from the Society to Glasgow to discuss with a committee of their Glasgow brethren the proposed Federation and the holding of a Scottish Congress. The Glasgow Committee agreed to a Federation being formed, and it was proposed that draft schemes be prepared by each Society and thereafter a joint meeting be held. It was agreed that subscriptions for a country member to either society should not be less than 10s. per annum. This joint meeting of committee had been fixed for Friday, April 21, in Edinburgh.

The Committee of the Glasgow Society approved of the holding of a Congress in Edinburgh in 1923, and recommended that they should collaborate with their Edinburgh brethren on the subject. Questions of how much would be required to run such a Congress were discussed, and it was remitted to the Federation Committee for consideration and report.

Mr. Fergusson and Mr. Yerbury were co-opted members of the Committee, and it was resolved that the Society entertain the Glasgow Committee, who are coming to Edinburgh on the 21st inst.

The meeting thereafter considered the formation of a Federation between the Edinburgh and the Glasgow and District Professional Photographers' Societies, in order that professional photographers throughout Scotland may become directly interested in the activities of the profession. Various theories were put forward and discussed in detail, and it was suggested that a circular should be prepared, setting forth the aims and objects of the Federation and the benefits to be obtained by professional photographers joining one or other of the societies to which they would be allocated. It was resolved that Scotland and the North of England be subdivided into two parts, and that professional photographers in the provincial towns be invited to join the society allocated to it; that the societies form a Federation and each society appoint a joint committee to manage the affairs of the Federation; that each society contribute to the Federation a fixed sum per member towards the funds of the Federation, to be applied towards propaganda work, exhibitions and lectures. It was proposed to suggest this scheme to the Glasgow Committee at the meeting on the 21st inst. and thereafter continue the discussion.

A vote of thanks to the President terminated the proceedings.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—The Society is holding its annual meeting and conference at Blackpool during the Trades' Exhibition there from May 15 to 20. All professional photographers in the North of England and in Scotland will be invited. Special facilities will be provided for exhibitors, since the promoters have taken over from the Blackpool Trades' Exhibition the whole of the stands for the week, together with the electric lighting and other equipment. Particulars from the secretary, Mr. W. H. Hulsh, 39, Blackfriars Street, Manchester.

News and Notes.

Mr. A. S. Ray, who is very well known in photographic circles, and who for many years has represented Mr. T. K. Grant for the Lumière products in this country, has just joined Messrs. Griffin's as representative in the northern part of England and in Scotland.

Mr. George J. Hughes, formerly of Waterford, and now established at Bridge-of-Allan, sends us an attractively printed booklet of reproductions of his artistic work in portraiture and also in landscape. Among them are works which have won awards in notable open exhibitions.

Avoid Printing Failures.—Under this title Messrs. Griffins, Kemble Street, Kingsway, London, W.C.2, have just issued a free instruction booklet dealing with the making of prints on their "Noctona" (gaslight), "Goldona" and bromide papers. The booklet contains many practical hints, and also formulæ for brown, blue and green tones on "Noctona."

Hand Cameras at Lower Prices is the title of a 72-page list just issued by the City Sale & Exchange, 81, Aldersgate Street, London, E.C.2. In the preparation of this closely printed catalogue of a part of the firm's large stock regard has been paid to the reduction in prices, which are now on a considerably lower level than at the corresponding time last year.

A Few Wise Words from Wellington.—A spring booklet from Messrs. Wellington & Ward announces in an appropriately lively vein some forthcoming introductions from the famous Elstree firm, including the twelfth edition of the well-known Wellington Handbook, which will contain an additional chapter on cameras, a revised article on the Bromoil process, and will be illustrated in photogravure.

Self-Desensitising Plates.—According to a patent No. 175,296 (applied for but not yet accepted) in the name of K. Wiebking, Weissenburg, Germany, to the back of a sensitive plate is applied a coating of gelatine, gum arabic, or isinglass containing safranine or other desensitiser which is soluble in the developing solution. This enables the development of the plate to be completed in a pale yellow light. An anti-halation medium such as manganese dioxide may be included in the coating.

Westminster Photographic Exchange.—A 56-page price list of cameras and other apparatus has just been issued from 111, Oxford Street, London, W.1, and represents a systematic marking down in the prices of the whole stock held by this leading firm of dealers in second-hand photographic requisites. The list fully describes a very great number of hand cameras of all types, and, moreover, offers a large variety of lenses and miscellaneous accessories. Obtainable free on application to the address given above, or to the other establishment of the Westminster Exchange at 119, Victoria Street, London, S.W.1.

Boat Race Photographs.—The many professionally-made photographs of the Oxford and Cambridge Boat Race this year were, as a whole, very much better than those taken in previous years, particularly the cinematographic renderings. Many photographers were given special facilities this year, and operators belonging to one firm were allowed to have their cameras on the two University launches which accompanied the umpire's launch. This is the first time these launches have been allowed so near the actual boats, and the result is practically a "close up" of the crews from start to finish. In the past cinema cameras had to be content with precarious perches on bridges or stations on the banks.

Wiggins Teape and Co.—The directors of Wiggins Teape and Co., Ltd., have concluded a provisional agreement with Mr. F. D. Pirie, acting on behalf of the ordinary shareholders of Alex. Pirie and Sons, Ltd., whereby the former company is to acquire up to 600,000 consolidated ordinary shares of £1 each in the capital of Alex. Pirie and Sons, Ltd., at the price of 16s. 8d. per share, to be paid and satisfied wholly in fully-paid £1 ordinary shares taken at their nominal value. This will effect an exchange of shares in the proportion of six shares of the Pirie Co. for five shares of Wiggins Teape and Co. To give effect to the arrangement it will be necessary for Wiggins Teape and Co. to increase its capital of £2,000,000 by the creation of 500,000 additional ordinary shares of £1 each.

Eye-Training with the Camera.—Criticising some statements made in the "Daily Chronicle" by a writer on art matters, Mr. Gordon Ivey, in a letter to the Editor, says: "There are two points of view: (1) To 'see' because one has one's eyes open and anything visible will naturally be recorded in a very elementary and temporary fashion; and (2) to 'see' with the eye of constructive critical observation which records itself permanently in one's mind. The latter requires interest, appreciation of art, and sympathetic understanding of the blending of light and shade to form contrast: this can be acquired by anybody who will just use his eyes. If one feels that he cannot cultivate the 'seeing eye,' let him go in for photography, that will compel the eyes to 'see.'"

The "Weekly Dispatch" Competition.—Professional photographers appear to be doing well in this competition, in which good cash prizes are offered weekly for "mother and child" photographs, prizes going to the subjects as well as the photographers who make the pictures, and special show-cards for window-display are issued to professional workers. Judges award the prizes each week, and at the end of the 16 weeks during which the competition lasts, a committee will select from the weekly prize-winners twelve competitors whose photographs make the prettiest, healthiest and most appealing pictures, and readers will be asked to vote upon them for the award of a first prize of £100, a second of £25, and a third of £10. Entries are also invited to a further competition for the best photograph of a child taken with one of its grandparents. For this a weekly prize of £2 2s. is offered, and at the end of the competition a final prize of £10. The names of several well-known workers have already appeared in the prize lists.

THE NEED IN PICTORIAL PHOTOGRAPHY: AN ACADEMY.

To the Editors.

Gentlemen,—I feel a few words of appreciation of Mr. Tilney's recent paper ("B. J.," March 31, 1922) will help to strengthen his statements on pictorial photography. He has put his case in a very strong fashion, and I am prepared to support most of his statements, all but the dramatic remark of his isolating himself in a wilderness; that is more funny than true. Surely, Mr. Tilney has lived long enough to find a few men as wise as himself; men who have been preaching the same gospel of art, men who not only have preached by words, but by works, many of whom have accomplished much for the pictorial side of photography. One of the best men who ever uttered a word in support of pictorial photography was our esteemed friend, the late Snowden Ward; his words and examples still live, and he led many a man to realise the right proportion of the picture.

I quite agree with Mr. Tilney that the bulk of the works now produced are bad, and the workers go blindly on copying and repeating the same mistakes, applying the methods that are absolutely wrong from beginning to end.

I contend that to fully realise the power of the photographic process in art there will have to be established a proper school or academy for teaching under well-organised conditions by men who know, and there seems to me only a few men in England who possess the gift of the real outlook; men who are seriously convinced of the truth of seeing correctly and have the capacity of reproducing these truths to paper. I personally feel that several of these men can top the average portrait painter of to-day. Photography will eventually occupy its rightful position in art, but the strange thing is the professional of the future is not being created in the studios of to-day; the leaders of the art will issue from quite a different source. I am convinced the public are learning, and learning to appreciate the good things even faster than the studio man is himself, and I contend that before many years half the studios of to-day will be closed, whilst new individual workers will rise, men of good, solid knowledge of art and all the details

required to produce one thing. This change is serious on the one hand and a welcome sign on the other; what is required is the Association to be so strong that it will be able to help the profession over the change.

Many of the new workers are much too freakish and fickle to last; there is too much evidence in their work of cheap copy without personal knowledge as to the why and wherefore. Mr. Tilney is quite right in most of his teachings, and it will pay all photographers to read and re-read his article until the dawn of the new light grips every man of the profession.

The serious questions for every studio man to ask himself are:—Where did we start from? What are we doing now? Where are we drifting? Then let us assemble our ideas into a solid form and with the Talbot Fox fund let us establish the Academy in memory of our great founder.—Yours sincerely,

MARCUS ADAMS.

43, Dover Street, London. April 4.

PRESENT-DAY TECHNICAL QUALITY.

To the Editors.

Gentlemen,—I was interested in your leading article of April 7, which appeared to me to represent here and there a school of thought in photographic technical matters considerably different to that to which I and some others belong.

The following quotations from the leader indicate this difference:—

(*a*) "With correct exposure, development becomes a simple task, and the necessity for a number of special printing papers to compensate for bad negatives is almost entirely eliminated."

(*b*) "There is a mischievous doctrine that certain classes of negative are required for different printing processes, and this has been the cause of much poor work."

(*c*) "What might be called a good negative is one which can be printed successfully by any process, etc., etc."

I hope that the meaning of the quotations has not been mutilated by their removal from the context.

Admittedly the correct exposure of the plate is as essential to-day when there are many printing processes available as it was in the days gone by when only a few printing papers were known. The "badness" of a wrongly exposed plate cannot be compensated for in printing. But I, recently, and many others before me, have preached that the quality conferred upon a negative by development is that of "contrast," meaning by that term the magnitude of the range of light-intensities which it transmits during the act of printing. I believe it to be a fact that different printing processes do require varying ranges of light-intensities in order to produce the same results, and that given appropriate negatives all printing papers can be made to yield exactly the same result, the colour of image and the character of the surface excepted. If this be true, and the truth thereof can be readily established by simple experiments, it follows that:—

(1) Development is the difficult task of fitting the range of the negative to that of a particular paper—a contradiction of "*a*."

(2) Negatives of different "contrast" are required for different printing processes—a contradiction of "*b*."

(3) A negative, no matter how good, will yield different prints with different printing papers because of the different properties of those papers.

With regard to (3) I am aware that occasionally a negative is produced which will yield a pleasing result upon several different printing papers. Nevertheless, the prints are different in appearance and they remain equally pleasing because the type of subject is such that the several renderings are agreeable. The virtue is in the subject and not the negative. Can it be seriously suggested that a negative can be so excellent in technical qualities that it will both yield a good print on vigorous gaslight paper and P.O.P., or be capable of yielding similar prints on platinum paper and in gum printing?—I am, yours very truly,

B. T. J. GLOVER.

Sunnymere,
Birkenhead Road, Meols,
April 8, 1922.

[As stated in the first few lines of our article, the notes on development and printing papers related to portrait work, and perhaps we should have said, to commercial portrait work. While we cannot deny Dr. Glover's theorems Nos. 1, 2 and 3, we still hold the opinion that within the scope of work to which our article referred negatives may be made which for practical purposes print equally well in such different printing media as P.O.P., bromide, gaslight, platinum and carbon. We say so because we have used many such negatives in these different media; in fact have made them. So far as we can discover, the versatility of such negatives is not accounted for by the accepted sensitometric doctrines, in regard to which the fault plainly lies with the doctrines and not with the negatives.—EDS., "B.J."]

EQUIVALENT PLATE-SPEED NUMBERS.

To the Editors.

Gentlemen,—I was very interested in the article on plate-speed numbers in the current "B.J.," and quite agree with you that anyone who, like M. Clerc, seeks to express the relationship between the different systems of plate-speed rating is attempting a very difficult task.

M. Clerc has arrived at certain comparative figures, which are supposed to represent the same plate speeds under the different systems in vogue, but do they? The German and Austrian systems do not concern us, but the H. & D., Watkins and Wynne systems do concern us very much, because they are all used by English plate makers. The H. & D. numbers appearing upon plate packets to-day do not agree at all with M. Clerc's table—in fact, they are practically double for the Watkins equivalent. That is to say that a plate of Watkins speed 360 would be marked H. & D. 500, whereas according to M. Clerc's table it should be about 245, and his H. & D. figures are somewhat higher than Eder's.

These higher figures are of little importance, however, so long as we are accustomed to them and we can obtain a proper equivalent as an actinometer number, but when it comes to an attempt to synchronise the Watkins and the Wynne numbers we get on to much more difficult ground.

The comparisons given by M. Clerc are the usual ones which appear to be accepted by most authorities, and are based upon mathematical formulæ, which, I believe, are agreed to by the respective meter makers. I submit, however, that they are incorrect, and also that a proper comparison is a practical impossibility for reasons that I shall endeavour to explain.

In comparing the exposure scales of the two meters it will be found that the equivalent speed numbers assume that the time required to obtain a tint match is 50 per cent. greater with the Watkins than with the Wynne meter, i.e., a ratio of 1½:1, and this is correct, when the tests are made direct to very bright sunlight, but, with the same strength of light, if the tests are taken in the shadow of the body and facing the sky, the ratio changes to 2:1. If a number of tests are made under a variety of lighting conditions—both indoor and out—it will be found that the ratio increases to as much as 8:1.

Which meter will indicate correct exposure is another question, but I submit that to attempt to make a true comparison is bound to end in failure.

E. A. BIERMAN, F.R.P.S.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—We cannot but demur to Mr. Bierman's description on p. 190, "B.J.," March 31, of the system of half-tone operating used by us at the L.C.C. School of Photography and Lithography. In that system the aperture ratio and the screen ratio are kept constant, but he makes us change the stop with different screen rulings, which is contrary to our practice. It is not to be assumed that we regard this system with any degree of finality, but we consider it the most complete and simple with which we are at present acquainted, and it has stood the test of commercial practice. We are by no means clear as to what is comprised in the "pinhole theory," but we have used as a working hypothesis the idea that the varying exposure in the penumbral shadow of the screen is the controlling factor in the formation of the different-sized dots. Whether it is really the effect of this, or of the plate characteristic, or of the scatter in the film, or of

diffraction, has yet to be demonstrated. Mr. Bierman's statement regarding diffraction is interesting, and we await with interest the publication of his experiments.—Yours faithfully,

W. J. Smith, F.R.P.S.
E. L. Turner, F.R.P.S.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. K.—The Tudor cameras are, or were, made by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, from whom perhaps you may be able to obtain plate-holders

E. F.—We cannot identify the camera from the description in your letter, but cameras of this kind of all makes are supplied by Messrs. Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2. Your best plan would be to apply to them for particulars.

S. Boyle.—A lens bearing the mark of 1748 cannot be what is now called a "rapid rectilinear." So far as photographic lenses are concerned we do not think your instrument has any historical value, and probably it has no such value as a specimen of pre-photographic lenses.

H. E. H.—In many places the police authorities require a hawker's licence to be taken out by people carrying on the class of business you describe, while in other places the police do not place any such restriction. We should think you would not run any risk in starting without a licence. If you were pulled up you would then have to obtain a hawker's licence.

G. G.—So far as we know there is no particular reason why the chrome alum should be used in any definite proportion to the metabisulphite. The metabisulphite is the anti-stain constituent, and requires to be present to the extent of, say, one-twelfth to one-twentieth of the hypo. The chrome alum determines the degree of hardening, and an average strength for this purpose is from 3 to 5 per cent.

E. F.—A power of 400-c.p. is not nearly enough. We should say 1,000 is the minimum, used either as one lamp or two, but 2,000, that is two 1,000-c.p. lamps, would be better. A good deal depends on the size of the room and the colour of the walls. In a comparatively small room, with light walls, you could do with somewhat lower power, but in any case we do not think you can very well go below the powers we have mentioned.

M. F.—We can quite imagine that the metal surface repels mountants such as starch and dextrine. We think you could mount the prints with a solution of shellac in spirit, which is a bit tricky to use but quite practicable, at any rate if the prints are not of very great size. Another mountant, which perhaps would be satisfactory, is gelatine used hot, that is to say, the mountant liquefied by heat and the latter quickly put on the mount. Again, if prints are of large size this is not an easy process, but is facilitated by working in a well-warmed room.

G. W. N.—You can procure the tracing cloth from any firm selling engineer's draughtsman's materials, such as J. Halden & Co., 15, Broadway, Westminster, London, S.W.1, or Winsor & Newton, 37-40, Rathbone Place, Oxford Street, London, W.1. If your lamp cabinet is to be a fixture it will be advisable to have an extra lamp as a high front light, or you will be able to get very little variety in your lighting. If your half-watts are on the opposite side of the sitter from the window, we should advise blocking out the daylight, as it would be very difficult to balance the two sources of light of different colours and values.

J. U.—(1) The folding focal plane camera of the Goerz Anschutz type, it is used by the majority of Press photographers. (2) In proportion as you increase aperture (for a given focal length) you decrease depth. There is no way out of this difficulty. The reason why you observe such great depth in cinema pictures is that these are taken with a very small lens of about 3 in. focal length, and, say, *f*/4.5 aperture. The depth in the small pictures is, therefore, very great, and when they are enlarged on the screen the want of sharpness is not observable at the average distance of the spectators. For high-speed Press work with a 5 x 4 camera *f*/4.5 is about as large an aperture as can be usefully employed. If of half-plate size, we think *f*/6 or *f*/5.6 is as fast as it is well to have.

J. B. A.—Hydroquinone stain, if heavy as that on your negatives appears to be, is difficult to get rid of. About the best means is a process worked out some year or two ago by the Ilford Co. and consisting in using a solution which, at one and the same time, bleaches the negative and acts upon the stain. This solution is :—

Potassium permanganate	50 grs.	5.7 gms.
Common salt	¼ oz.	12.5 gms.
Acetic acid (glacial)	1 oz.	50 gms.
Water	20 ozs.	1,000 c.c.s.

If the negative is one freshly made, it is as well to pass it through a weak bath of chrome alum (about 50 grains in 10 ounces of water—i.e., 10 gms. per litre) before applying the bleacher. The latter is allowed to act for ten minutes, rocking all the time. It cannot harm the gradations of the negative, and this full time makes sure of the removal of the stain, and avoids a repetition of the process. After a brief rinse, the negative is left in a solution of potass metabisulphite (1 ounce in 20 ounces of water) until white everywhere to the back of the film, and is then re-developed in any non-staining developer.

G. Y.—It would take too long to give detailed instructions by letter for fitting studio blinds. You will find them with diagrams in "The Portrait Studio," which our publishers will forward for 1s. 3d. post free. Dark casement cloth, blue, green or brown, will do for the dark blinds, but be careful that the colours will not fade. White nainsook or madapolam, which you can get from any draper, is best for the white ones. Backgrounds are usually 8 x 8 ft., but smaller ones, about 7 x 5, will be sufficient for heads or half-lengths. It is better to have them fixed upon frames as you can then place them where you please. It is a good plan to finish one end of the studio with a dado and frieze like an ordinary room to serve as a group background. Ordinary light brown linoleum is best for the floor, with a small carpet or rug to lay down for indoor full lengths. Messrs. Marion, Kodak and Griffin all specialise in backgrounds. We cannot say whether your customers would appreciate P.O.P. portraits. It would be wise to give them the choice of these and bromides. We do not think it matters to the public whether you use the initials M.P.P.A. or not.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3233. Vol. LXIX. FRIDAY, APRIL 21, 1922. Price Fourpence.

Contents.

SUMMARY.

Next week's issue of the "B. J.," that of April 28, will contain a full advance notice of the "Photographic Fair, drawing special attention to the many new goods which are to be shown there for the first time by exhibitors. (P. 225.)

Good use of that portion of the overhead charges of a studio represented by the window display is the theme of an article by Mr. Mervyn Thompson, whose advice is prompted by the different kinds of display employed by two adjacent studios. (P. 227.)

We publish an interesting photograph of three veterans of professional portrait photography—Messrs. E. Ireland, Lafosse and Warwick Brookes, all of Manchester. (P. 228.)

Some of the means which may be taken during a season of flatness towards the reconstruction and improvement of a photographic business are the subject of an article on page 226.

At a recent meeting of the Lancashire Society of Master Photographers Mr. Percy Guttenberg had many valuable hints to give on the business management of a photographic studio, and afterwards gave a demonstration in his own studio of posing and lighting by artificial light. (P. 236.)

The condemnations by Dr. Henry B. Goodwin of theatricality in photographic portraiture, delivered at an R.P.S. lecture, will be found reported on page 235.

In the concluding part of their paper on the gloss of photographic papers Messrs. Loyd A. Jones and Milton F. Fillius, of the Eastman Research Laboratory, bring together a number of the results of their measurements. (P. 229.)

Convenient practical forms of background reflectors are described in a paragraph on page 226.

A fitment for the making of lantern slides by the use of an enlarging installation is described by Mr. D. Charles in "Assistants' Notes." (P. 232.)

The service which careful choice of a border tint may render in improving the appearance of a faulty print or enhancing that of a good one is referred to on page 226.

A very simple formula may be used for ascertaining the best point on which to focus for the purpose of avoiding unnecessary stopping down of the lens when making large scale photographs of small objects. (P. 226.)

The making an application for a provisional patent specification is an inexpensive means of obtaining protection for an invention for a limited period, with option to abandon the publication of details which the completion of a patent involves. (P. 225.)

A specification dealing with the design and construction of the Eastman vertical self-focussing enlarger will be found under "Patent News." (P. 233.)

EX CATHEDRA.

The Fair. Further information which has reached us of the exhibits to be shown at the Photographic Fair, opening at the Horticultural Hall, Vincent Square, Westminster, on Monday week, May 1, shows us that the visitor, whether professional, amateur, or dealer, will have so much to see that no one wishing to know of the many new goods coming on to the market for the coming season can consider for a moment the possibility of absence from this gathering of the manufacturers. Among makers of cameras and other equipment for amateur photography reduced prices claim as great a share of firms' propaganda as the many new models and kinds of apparatus, a two-fold description of progress which must inevitably draw within the ranks of active photographers those who have perhaps held aloof during the past two years. The caterers for the professional photographer are equally active in these respects, and in the display of portraits on the latest grades and varieties of printing media offer for the professional's inspection collections of work which in the aggregate are comparable with the exhibition of portraiture by leading professional photographers in the United States which forms one of the special features of the Fair. The particular kind of result which a printing paper yields is one of the most difficult things to describe or to show by one or two specimens, and probably portrait photographers have no better opportunity in the course of the year of fully informing themselves of what manufacturers are doing for them than at the Fair. As already announced, bona fide professional photographers may obtain a pass for the whole period of the Fair for the sum of one shilling on application to the Organising Secretary, Sicilian House, Sicilian Avenue, Southampton Row, London, W.C.1.

* * *

Protecting Inventions. From time to time we are the recipient of often confidential enquiries from readers who have perfected some new photographic requisite—such as a piece of apparatus, material used in the making of negatives or prints, or some chemical preparation. The enquirer naturally has the wish to profit by his originality, and usually is in doubt of the best course to take for that purpose. While the advisable course differs according to the invention, there is one thing which applies to any novelty, and that is, protection of the invention, at any rate, until some arrangement has been come to with a manufacturing or other firm. Many of the leading firms, in fact, make it a condition that an invention shall be protected before they will receive particulars of it, for the obvious reason that they do not wish an inventor to be able to charge them with having taken any unfair advantage of him. Although the full protection of inventions by letters patent is a complicated and costly business, it is fairly

simple and inexpensive at this initial stage, for provisional protection, lasting for a period of about nine months, is obtainable at the cost of £1, if the inventor draws up his provisional specification himself, or for a pound or two more if he employs an agent. During this time he is protected from the date of his application, and if on negotiation it is thought undesirable to allow the details of the invention to be published, as they would be in a complete specification, the application may be dropped at the provisional stage, so that even such particulars as have been given in the provisional specification are not published, since the Patent Office issues copies only of such specifications as are completed, accepted and sealed.

* * *

Background Reflectors. The orthodox studio reflector is rather an expensive item nowadays, and many photographers now prefer a home-made article. A frame covered with white calico with a hinged strut answers the purpose perfectly, but for fancy lighting, in which more than one reflector is needed, it will be found advantageous to construct the second one so that it will serve on occasion as a white background for heads and sitting figures. Six feet by four is a convenient size, and the frame should be fitted upon feet or brackets so that it will stand vertically. One side should be distempered white and the other a rather light grey. This latter colour is useful, not only as a background, but as a reflector when white would be too glaring. As an alternative, one side may be painted a dead black, forming a useful background for some classes of portraits or commercial work. Care must be taken in mixing black distemper to avoid an excess of size, which gives a slight gloss. The colour is improved for photographic purposes by mixing in a little Venetian red, which gives a warmer tone to the eye and a more non-actinic colour in working.

* * *

Border Tints. There is a great temptation in dry-mounting photographs to introduce a border tint, whether it be necessary or not. Although many portraits show to the best advantage upon a perfectly plain mount, there are others whose shortcomings can be minimised by using a suitable border. Thus, a hard black and white print is rendered more harmonious by mounting upon a pure white board with a black tint. Conversely, a flat greyish print is better upon a mount and tint, neither of which is lighter or darker than the highest light or deepest shadow in the subject. Prints which are unsatisfactory in colour can be improved by choosing a suitable tint. Thus, a print which is brownish, or perhaps, more correctly, rusty looking, should be mounted on a warm toned border, which by contrast makes the image appear blacker. A cold grey would have the effect of making such a print look still more rusty. As a general rule, warm French greys, buffs and browns will be found most generally useful, with black and white for special effects.

* * *

The Point to Focus On. Among the many formulæ relating to depth of focus there is one which has a greater practical usefulness than many others, since it does not involve the much-discussed standard which may or should be taken for the diameter of the disc of confusion. This formula is that which gives the distance from the camera on which one should focus if the best available definition is to be obtained also on a nearer and a more distant object. In the case of subjects, all the parts of which are at a relatively great distance from the camera, the formula is not of much importance, since any required definition is readily obtained by stopping down the lens, depth being great in those regions of the object space which are at considerable distances from the lens. On the other hand, if a quite near object, *e.g.*, a mineral specimen, is being photographed on a large scale, such as same size, and therefore is necessarily close to the lens, depth is very small, and it is worth while to ascertain by simple calculation what is the best point on which to focus. On then stopping down the lens the minimum waste of definition will be secured with any given stop. The formula is as follows:—Multiply the distance of the further point from the diaphragm by the distance of the nearer point and then by 2, and divide the product by the two distances added together. Thus, if the furthest point is 5 ft. and the nearest 3 ft., the distance on which to focus is $5\times3\times2\div(5+3)$, that is to say, $3\frac{3}{4}$ inches. In other words, we should focus on the part of the object which is 9 inches behind that portion of the object nearest to the camera.

SLACKNESS AND PROGRESS.

THERE are one or two months, sometimes more, in every year in which orders for portrait work become few and far between, and during such periods the photographer usually becomes despondent and wonders why he did not choose some occupation less seasonal in its character. When trade revives this melancholy vanishes, not to return till the next dull period. A very useful tonic in such cases is to adopt the plan of making a chart on which the rise and fall of the business barometer can be recorded week by week, which will show that in a properly-conducted business such fluctuations are normal, and, provided that the year's takings are well maintained, need cause no anxiety.

In a progressive art like photography these periods of leisure may be utilised to the profit of the artist, if he is sufficiently in love with his work and wishes to raise its standard year by year. It is a mistake for the humblest photographer to think that his work is good enough for his customers, and not to trouble to do better. Customers may accept their portraits and consider them as good value, but in these days of cinemas, illustrated magazines and picture shops, there are few who are so uneducated as not to appreciate good work when they see it. Now, it is a remarkable fact, which few seem to appreciate, that it is no more trouble or expense to make good photographs than to make bad ones, once the way of making good ones has been mastered, and the slack season gives the opportunity for this to be done.

A photographer, whose name is well known in the profession, says that when a young beginner, being discouraged by the difference between his work and that of the best portraitists of the day, he reasoned thus: "My lens will give as good definition as is shown in these pictures, I can buy the same plates and papers, I use the same daylight. Why, therefore, is my work inferior"? It was obvious that the fault was with the producer and not the materials, so securing a few really good specimens he set to work in dead earnest to make something like them, taking negative after negative, until a near approach to the desired standard was attained. The printing problem was next attacked, with the result that a soft warm-toned picture superseded the hard purple-black results of his early efforts.

Not everyone is in need of such drastic reformation as this, but there are few experienced workers who would not be the better for taking stock of their methods and endeavouring to bring them up to date. Unfortunately,

there is some little difficulty in obtaining specimens of the best work for comparison, and the exhibitions are little helpful in this direction. In the old days, when the Exhibition in Pall Mall was devoted to the technical rather than the artistic side of photography, the humble professional had the opportunity of seeing what was then considered the highest class of work; now small every-day work is never seen. If the P.P.A. could include a section of such work in their exhibition it would be of the greatest educational value.

Apart from improving the general style of work there are many matters of detail to which attention may be turned in times of leisure. There is such a multiplicity of plates and papers now on offer that it is impossible to tell, without actual experiment, whether a more suitable grade might be selected in place of that already in use, and this cannot be done in a perfunctory way. It is quite a common practice to test a fresh brand of paper with the developers already in use, irrespective of the fact that a special formula is necessary, with the consequence that the paper is condemned as inferior to that which is being used with its appropriate solutions. The same thing occurs with plates; a new brand of high speed requiring long development is treated in the same way as a slower, quick-developing plate, and is found to give flat thin images. If the maker's word is to be relied upon—as practically it always can—it is up to the photographer to follow the instructions given until success is attained.

As it is with materials, so it is with apparatus. Many photographers have at one time or other bought lenses with which they have been disappointed, this being specially so with those of the soft-focus variety. These require a special study to be made of focussing, and this cannot be done while a sitter is waiting. Once mastered by a few experimental exposures on the same model, these lenses are as easy to use as any others, softness in the place of fuzziness being afterwards readily attainable.

Another direction in which spare time may be employed with profit, not only to the individual but to the whole profession, is in the instruction of assistants. We have letters from time to time on the ignorance and incompetence of those who apply for work. Who is to teach them but their employers. It may seem altruistic to recommend teaching a youth to do good work when he may at any time leave "to better himself," but a moment's reflection should show that if he is worth more money to another photographer it is time the original employer raised his wages.

The necessity for making structural alterations in the premises, repairing and remodelling apparatus, renewing blinds and all work of this class during the slack season should be so apparent that it hardly needs pointing out, yet it is often neglected because there is little or no money coming in. It should be remembered that facilities for working mean increased profits, and that such work can usually be obtained more cheaply before the spring rush of decorating and building begins.

A QUESTION OF OVERHEAD CHARGES.

Passing down one of the principal streets in the West End, I stopped to examine carefully the window display of a particular photographer. The portraits were displayed in close formation upon a panelling of dark oak, and must have numbered nearly a hundred. The quality of the work was excellent. The combined cost of the fittings and specimens must have represented something very considerable in cash outlay, both in the initial stage and to maintain. In spite of the expensive "get-up" I was not particularly impressed. I did realise that here was a photographer's shop where work of reasonable quality was produced, but that was all.

Strolling along I presently came across another photographer's. Accepting a certain standard of technique to be common to both, it would have been extremely difficult to find two businesses, that upon a first acquaintance, appeared to be administered in a manner so completely different. In this second case a few simple hangings and less than half a dozen specimens represented the photographer's "appeal" to the public. The cost, compared with the other man's oak and brass plates, was surely infinitesimal! Here, I felt, was not only the photographer but the artist—and yet I was conscious of something more.

During the next two months business took me into the neighbourhood, and I set myself to spend a few minutes each day in careful observation. I found the shop with the panelled oak did attract, but in a very superficial manner, whereas the other window seemed to draw the public in a much greater degree. Passers by not only stopped to look into this window but, having looked at the photographs, looked up again at the shop. The shop attracting in the first place drew recognition to the work; the specimens and the method of arrangement seemed to convey not only a photographer's work exhibited in a shop, but this photographer's and this shop. Here I thought was that something more—but not quite all.

Fifteen times was this window changed—seeming carelessly. A specimen added, a specimen taken away, a bowl of fruit in tumbling disarray pushed into the centre space, an alteration to the drapery, in any case a comparative triviality, but creating a distinct and definite change. Here, then, was that something—here was not only the artist photographer but the keen, alert, business man, who, realising the permanent liability upon his business by the very fact of his shop rent, saw that he got value for money. He gave the shop window his constant personal attention, and expended just as much of his care and skill upon getting people into his studio as he did when he had them there. I was not surprised when, at the end of five weeks, the window with the oak panelling was taken out, remained out two days, and was then replaced in precisely the same manner with exactly the same conflicting and monotonous effect.

Photographers, as business men, should realise to the full the meaning of establishment charges. The man with the oak panelled display laid out his money both in capital expenditure and recurring charges presumably of a very substantial nature. His shop rent, with rates, etc., added, probably represented his largest individual liability, which he apparently was content to leave to the care of a junior assistant.

Establishment and overhead charges are the big bug-bear of business. When things are slack less material is used, less labour employed, but rents and so forth remain substantially the same. It is one thing to reduce establishment charges to the minimum which is that all business men seek to do, but it is not enough. Such heavy expenses should be kept continually in mind, be continually reviewed, and be administered or applied with the utmost skill. It is only fair to your business.

I do not quarrel with the gentleman of the oak furnishings because of his oak or because of his hundred specimens; his

show probably served his purpose as well as the other man's. I do question his policy of leaving the matter in the entire hands of an assistant.

Photography as an art is appealing more and more to the artistic sense of the public. The days of the crude "likeness" are past. A photograph now is expected to render not only outline of form and feature, but something of character as well. By applying skill and technique to the careful consideration of the characteristics of the sitter and production of the finished portrait, the photographer hopes to give satisfaction and build up or increase his business. It is not too much to say that that same skill and consideration should be continually used for the administration of all your assets, in order to apply them to the greatest advantage, for the benefit of the business as a whole.

MERVYN THOMPSON.

A TRIO OF PHOTOGRAPHIC VETERANS.

IT IS not often that the opportunity occurs of making a photograph of three veterans of photography such as that which we reproduce on this page by the courtesy of Mr. C. Ireland, of Manchester, son of one of the sitters. The photograph represents Mr. Lafosse who is now 85, Mr. Warwick Brookes who is 76, and Mr. Ireland who is 79. They may justly be called the three veteran photographers of Manchester, and are all fortunately still hale and hearty and happy in their well-earned leisure. All three were enthusiastic in their art in the early sixties, and made their mark in one branch or another of photography at that time. Mr. Lafosse, perhaps, is notable chiefly for the share which he took in raising the photographic portraiture of his time to a higher artistic level. Those of us whose memory goes back a number of years readily bring to mind the characteristic beauty of not only his portraiture but his outdoor figure studies and landscape. Mr. Lafosse still retains his artistic talents, and employs himself almost every day in making studies in black and white after the style of George Shelfield, whose pupil he was. He is seen in the centre of the group.

Mr. E. Ireland, a most assiduous worker, may perhaps be described as the man of many studios, the arrangement and supervision of which absorbed his energies. He did much to popularise portrait photography not only in Manchester but in many of the adjacent towns. In his day the whole plate portraits, particularly by their artistic mounting, struck a high and meritorious note in studio portraiture.

For Mr. Warwick Brookes may be claimed the introduction of the present practice of negative retouching if not into Europe, at any rate into England. Both he and Mr. Lafosse brought retouching to a high state of technical perfection. For some time the method was a secret which puzzled competitors, and brought its possessors greatly into favour among fashionable customers. Mr. Brookes was the inventor of a small magazine hand camera, on which principle many cameras of this type were made, and obtained widespread popularity until the introduction of roll film rendered easier the design of much more portable instruments.

THREE VETERANS OF PHOTOGRAPHY. *Photograph by C. Ireland, Manchester.*
From left to right, Mr. E. Ireland, Mr. Lafosse, Mr. Warwick Brookes.

It is, of course, hardly necessary to mention that all three of these pioneers made their reputation, artistic, technical or commercial, in the days of the wet-plate process. At such gatherings as that shown in the group photograph they can be imagined as exchanging notes on the stages through which photography has progressed since their early days, and on the disappearance of the vagaries which attended the making of wet-plate negatives. It may perhaps be questioned whether they are of the view that the technical quality of modern studio work has advanced in correspondence with the facilities with which modern manufacture has endowed those of the present day.

THE GLOSS CHARACTERISTICS OF PHOTOGRAPHIC PAPERS.

(A Communication from the Research Laboratory of the Eastman Kodak Company.)

(*Concluded from page* 218.)

Results.

Effect upon Gloss of Variations in Illumination.—In order to determine the influence of the type of illumination used in illuminating the sample upon the resulting gloss values, the following series of measurements were made. Eleven samples of paper varying widely in glossiness were chosen. The gloss values for each of these were then measured, using a collimated beam incident at 45 deg. in illuminating the sample. The results of these measurements are given in Table 1 in the column marked "parallel." By removing the lens, D (see fig. 1), and replacing it with a disc of opal glass of proper dimensions, the sample was illuminated by a source subtending .01 of the steradian at the sample. A second series of gloss measurements were made and the results are given in Table 1 in the column marked "semi-diffuse." It will be noted that in all cases the values obtained with parallel illumination are higher. For instance, for the most glossy surface, the reading of the semi-diffuse illumination is 12.4, while with a collimating illumination a value of 24.0 was obtained. It is evident in both cases that for a glossless surface the reading must be zero. The use of

TABLE 1

Sample.	Parallel.	Semi-diffuse.
1	0.43	0.36
2	0.43	0.39
3	0.78	0.78
4	1.20	1.03
5	1.89	1.65
6	2.28	1.91
7	3.96	3.12
8	13.6	9.0
9	21.2	10.9
10	22.9	12.6
11	24.0	12.4

collimated illumination, therefore, gives a more extended scale and increases the ability to detect differences between samples varying but slightly in gloss value. For this reason, therefore, and also because a satisfactory brightness can be obtained more readily for this type of illumination, it was decided to adopt the parallel illumination as a standard condition for the measurement of gloss values.

Effect upon Gloss of Various Surface Treatments.—In order to determine the effect of certain surface treatments upon the gloss characteristics of various stocks, eleven samples of raw stock used in the manufacture of photographic papers were chosen as representing the entire range of gloss variations which occur with these materials as they come from the mill. The values of gloss will be found in Table 2, column 1. It will be noted that there is a relatively small variation in the gloss of these samples. Other samples from the same stocks were examined after having been coated with baryta. The gloss values obtained are shown in the second column of the table. A typical photographic emulsion was chosen, and by coating this on each of the eleven stocks selected a finished developing-out paper was obtained. Samples of each were fixed out, washed and dried in the usual way, and the gloss values determined. These values will be found in column 3. A second lot of emulsion containing a suitable material for the production of a more matt surface in a photographic paper was used in making up an additional set of samples from the same paper stocks. Samples from these were treated as previously, that is, fixed out without exposure, washed, dried and the gloss values obtained. The values determined are shown in column 4.

It is impossible to analyse completely the results shown in Table 2. The effect of the baryta coating is not the same in all cases, and this undoubtedly is due to peculiarities of treatment that occur in the process. However, it will be noted that in all cases the gloss values are increased appreciably by coating the various samples with plain emulsion, while the use of the matt emulsion reduces the gloss value in all cases. In fact, the gloss values given in column 4 are so nearly equal that but little variation in gloss is apparent in this group of samples.

TABLE 2.

Sample No.	1. Raw Stock.	2. Baryta Coated.	3. Plain Emulsion.	4. Matt Emulsion.
1	0.33	0.10	0.43	0.24
2	0.36	0.14	0.43	0.19
3	0.62	0.06	1.89	0.18
4	0.45	0.05	0.78	0.29
5	0.69	4.21	24.0	0.44
6	0.40	0.31	3.96	0.29
7	0.70	4.94	21.2	0.29
8	0.50	5.08	13.6	0.35
9	0.49	0.55	1.20	0.34
10	0.83	8.45	22.9	0.35
11	0.51	1.65	2.28	0.55

Variation of Gloss with Diffuse Reflecting Power.—When a photographic paper is exposed and developed, small particles of metallic silver are produced which, since they have a very low reflecting power, reduce the reflecting power of the surface. This blackening of the surface reduces the amount of light diffusely reflected without appreciably changing the amount of light which is reflected specularly. This follows from the fact that practically all of the specularly reflected light is that which is reflected from the surface layer of the material that is at the boundary of the air-gelatine surfaces. It will be seen, therefore, that when gloss measurements are made on photographic papers that have been subjected to varying degrees of exposure, a rapid increase in the gloss value must occur, since R_s remains practically unaltered, while R_d decreases to a very marked extent.

In order experimentally to determine the relation between photographic density and gloss, a series of measurements were made on the samples that had been subjected to various degrees of exposure, developed, washed, and dried in the usual manner. It might be well to point out at this place that the word "density" as used in this connection is defined by the equation D (density) = the logarithm of $\frac{1}{R}$ (reflecting power), where R is the value of diffuse reflecting power as measured under certain definitely specified conditions of illumination and observation.

Three standard photographic papers representing a low, medium, and high gloss were used for the determination of the relation existing between density and gloss. Numerical results are given in Table 3, and these are plotted in graphic form in fig. 5, curve A representing the variation in gloss value with

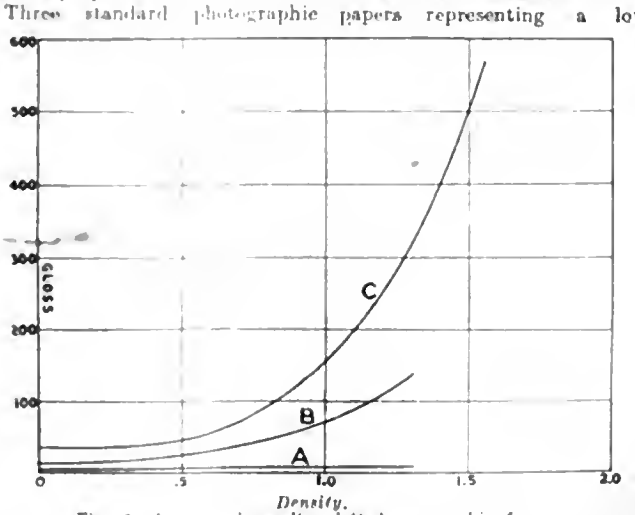

Fig. 5. Numerical results plotted in graphic form.

density for *Iris D*, curve *B* for *Azo K*, and curve *C* for carbon black glossy.

TABLE 3.

Sample.	Density.	Gloss.
Iris D	0.00	0.22
	0.36	0.39
	0.70	0.85
	1.02	2.00
	1.30	3.25
Azo K	0.00	4.30
	0.59	22.8
	0.92	51.0
	1.30	135.0
	1.70	307.0
Carbon Black Glossy	0.00	31.2
	0.40	29.5
	0.70	72.3
	1.07	157.7
	1.55	569.0

These results make it very evident in the case of photographic papers at least that some specification of the condition of the material under which the gloss measurement is made must be given. For photographic papers, it seems most logical to specify that gloss measurements be made on a sample which has been fixed out without exposure, washed, and dried in the usual manner. In the case of a photographic print which is made up of areas differing widely in density, usually from the minimum to a maximum density obtainable with the material, it is evident that no single gloss value applies to the entire surface—that is, gloss varies from point to point depending upon the density. While this makes it impossible to establish a fixed value of gloss to a photographic paper without specifying the value of its diffuse reflecting power, such a procedure seems to be in harmony with our fundamental concept of the term glossiness.

At first thought it may seem more logical to assume that a given surface should have a specific value in gloss regardless of other factors such as density, but a careful consideration of the problem leads us to the conclusion that our judgment of glossiness is very vitally dependent upon the diffuse reflecting power of the surface. Of, two surfaces having equal values of specular reflecting power, the one having the lower value of diffuse reflecting power will undoubtedly appear the more glossy. It has been suggested that in order to avoid the dependence of gloss upon the density, an absolute value of specular reflecting power be taken as a measurement of gloss. Such a procedure would seem to be in direct opposition to the fundamental concept of the word glossiness. As an illustration of this, let us consider the case of two equally well-groomed horses, one black and the other white, seen under a brilliant illumination such as a clear, sunny day. It is probable that the value of specular reflection in the two cases is approximately equal; and the high-lights produced by the specular reflection of the sun would be of about the same brightness, while it is undoubtedly true that a great majority of judges would say that of the two the black horse had the more glossy coat. Careful examination of samples prepared by exposing pieces of the same photographic paper to various extents and developing so that a series varying in reflecting power was obtained, indicates that glossiness increases as reflecting power decreases. The magnitude of the increase in glossiness, however, is not proportional to the increase in the value of gloss as previously specified. The correlation of the subjective sensation with the stimulus remains to be accomplished. It is probable that a method similar to that used in other fields of visual sensitometry involving the determination of the magnitude of change in the stimulus required to produce a just noticeable difference in the sensation will yield the desired results. The conclusion that our judgment of glossiness is a function of contrast seems inescapable, and, therefore, in the case of photographic papers gloss must undoubtedly be dependent upon density.

Gloss Measurements on Developing-Out Papers.—A satisfactory method for measuring and specifying gloss having been developed, and the effect of various factors upon gloss having been determined, a large number of samples of commercial developing-out papers were measured. As stated previously, certain words and phrases are at the present time used to designate in a qualitative way the gloss of such materials. There are a large number of such terms in use, but the four most commonly used are "matt," "semi-matt," 'semi-gloss," and "glossy." In Table 4 are given the results of the measurements. In column 1 is given the trade name of the material, and in column 2 is the term used by the manufacturer in designating the gloss characteristic of the surface, while in column 3 are the gloss values obtained by measuring under the standard conditions previously outlined.

The samples were prepared by taking an unexposed sheet of the material, fixing it out in a clean, fresh, acid-fixing bath, washing, and drying in the usual way. These samples were then mounted by the dry mounting process on sheets of aluminium about 1-16 of an inch thick. This method of mounting was found to be necessary in order to obtain precisely repeatable results. It is absolutely essential in doing precise work of this kind that the sample be mounted in such a way that it is held perfectly flat and smooth. If precautions are not taken to obtain perfect flatness very slight variations in the planeness of the sample introduces variations in the readings which are serious, especially in the samples having relatively high gloss. By using care in pre-

TABLE 4.

No.	1. Name.	2. Surface.	3. Gloss.
1	Magnesium Carbonate	Matt	0.10

24	Carbon Black	Glossy	31.2
25	Bromide Enamelled	Glossy	32.2
26	Solio Ferrotyped	Glossy	66.3

NOTE.—The values in this table were determined on samples taken at random from stock, and do not represent the standards for the materials indicated.

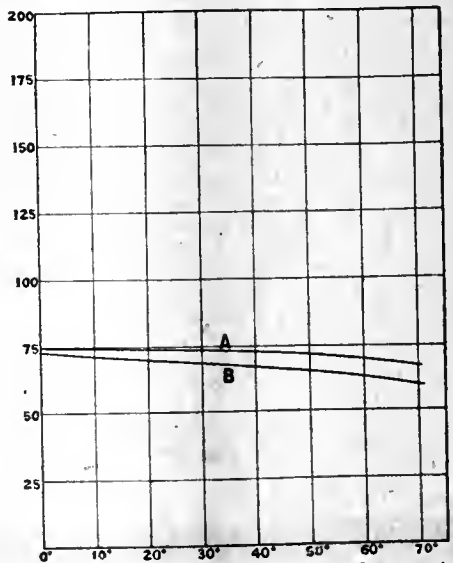

Fig. 6.—Distribution curves for samples Nos. 2 and 12.

paring the samples, it was found that values can be repeated from time to time to within approximately ± 4 per cent. The first value given in Table 4 is that for magnesium carbonate. This sample was prepared by taking a block of the material, and carefully scraping the surface with a steel straight edge. It will be noted by comparing the value of gloss with the terms used in the description of this factor that surfaces having values up to .67 are described as matt or carbon, while values ranging from 1.57 to 2.78 apply to surfaces described as "semi-matt" or "smooth." Only two surfaces designated as "semi-gloss" were measured, and for these the gloss value was 4.3. The range from 14.5 up to 66.3

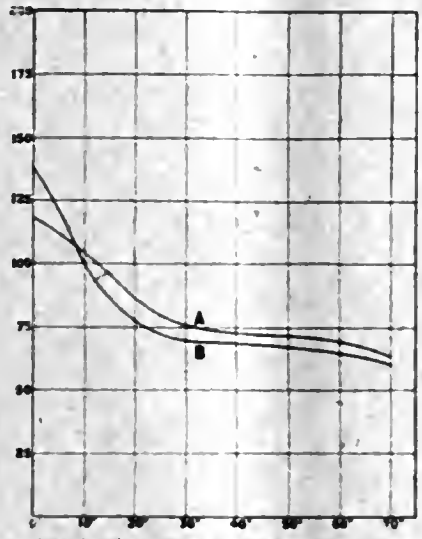

Fig. 7.—Distribution curves for samples Nos. 13 and 17.

applies to those surfaces designated as "glossy." Before reaching a final correlation between the numerical gloss values and verbal descriptions of the surface, it would be well to examine a much larger number of surfaces. However, on the basis of those already examined, the following classification is proposed.

In the following table are given the numerical ranges of gloss value which apply to the various descriptive terms. It is obvious that there is no distinct line of demarcation between the various classes, but it is convenient from the practical standpoint to make

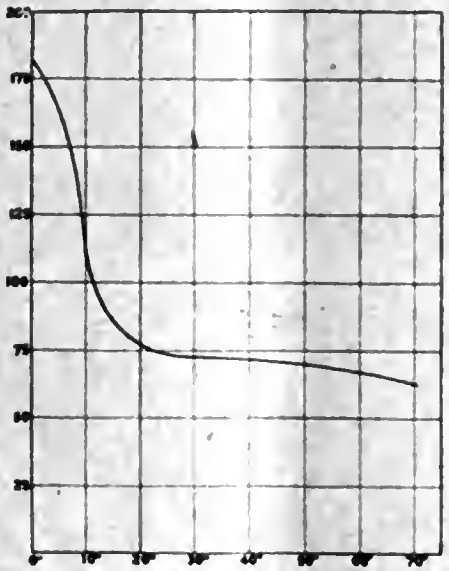

Fig 8.—Distribution curves for semi-gloss class.

a more or less definite division of the scale. The point separating the classes designated as "semi-gloss" and "gloss" is indicated as 7.0. This is a rather rough estimate since but few surfaces designated as semi-gloss have thus far been examined. It is possible that more complete data on the subject will make it necessary to alter the division point between these two classes, but at the present time it is thought that the value chosen is approximately correct.

TABLE 5.

Descriptive Term.	Range of Numerical Values.
Matt	0.0 to 1.0
Semi-Matt	1.0 „ 3.0
Semi-Gloss	3.0 „ 7.0
Glossy	10.0

In order to show the relation between gloss values and the distribution curve of the light reflected from the surface, it may be

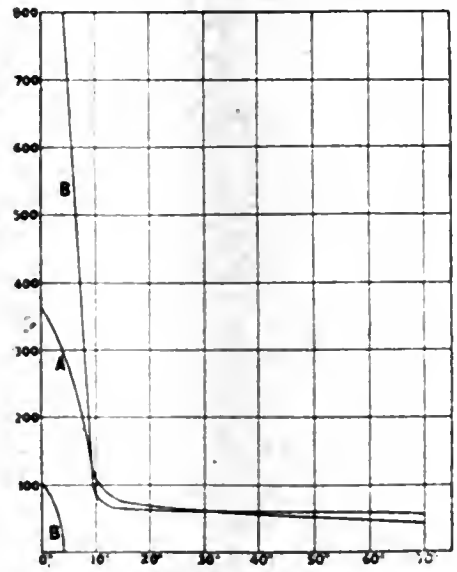

Fig 9 Curves for samples 20 and 25.

well to show graphically some of these distribution curves. In fig. 6 are shown the distribution curves for samples Nos. 2 and 12, these representing the high and low gloss values for the matt class of surfaces. These distribution curves were determined by illuminating the sample normally with parallel light and measuring brightness at various angles as indicated by the abscissæ values. The ordinate values are in terms of relative reflecting power, the reflecting power of the magnesium carbonate surface under normal illumination and observation being taken as 100 per cent. In fig. 7 are shown the distribution curves for samples

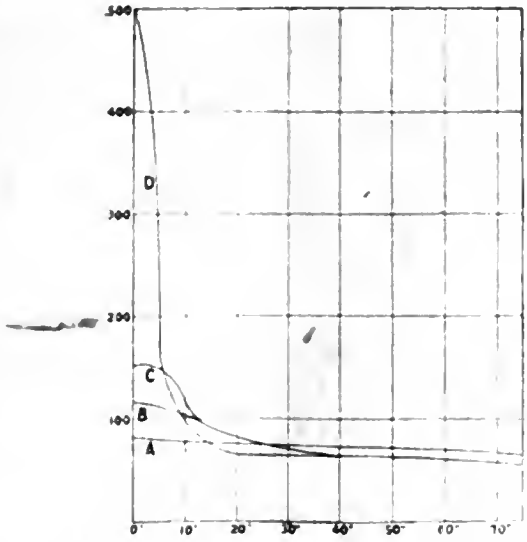

Fig. 10 Distribution curves of various classes of surface.

Nos. 13 and 17, these representing the high and low limits of gloss in the "semi-matt" class. In fig. 8 is given the distribution curve for the "semi-gloss" class. Only two examples of the classification were examined, each having a gloss value of 4.3. In fig. 9 are given curves for samples 20 and 25, these representing the limits of the "glossy" group. In order to show more clearly

the relation existing between the distribution curves of these various classes of surface, the four curves shown in fig. 10 are given. These curves represent a typical surface of each of the four groups, curve *A*, being that for sample 8, having a gloss value of .38. This value is the approximate average for the matt group. Curve *B* is that for sample No. 15, having a gloss of 2.00, this again representing the average gloss for the semi-matt group. Curve *C* is that for sample No. 19, being the semi-gloss material, while curve *D* is for sample No. 21, a typical representative of the glossy group.

THE ACTION OF LIGHT ON A PHOTOGRAPHIC FILM.

(A Note in the Journal of the American Physical Society.)

It is a well-known fact that there is a remarkable similarity between the photoelectric and photographic properties of the silver halides. This has suggested to several writers (cf. Allen's "Photoelectricity," Chap. XIV.) the possibility of explaining the action of light on the photographic film as due to some sort of photoelectric action.

Now it has been shown that when plane-polarised light is incident upon a photoelectrically sensitive surface, more electrons are emitted when the electric vibration in the incident light is normal to the surface than when it is parallel to it. Consequently a very narrow line if photographed through a Nicol's prism should appear sharper when the direction of the electric vibration is parallel to the line than when at right angles to it. This was tried experimentally and found to be the case.

The source of light consisted of a very carefully ruled set of rectangular lines on a plane white background. Between this source and the camera lens was a high-grade Nicol's prism. The lens was a good anastigmatic lens, and fine-grained, contrast photographic plates were used.

Several photographs were taken with the Nicol so oriented as to make the electric vibration parallel to the vertical lines and several with it parallel to the horizontal lines. In every case the lines parallel to the electric vector were the sharper. The direct image on the ground-glass of the camera was also examined with a magnifying glass, but no difference could be observed between the two sets of lines.

These experiments seem to indicate the possibility of explaining the effect on the assumption of some photoelectric action. The experiments are being continued in a slightly different manner with the object of finding some more direct evidence of the effect.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

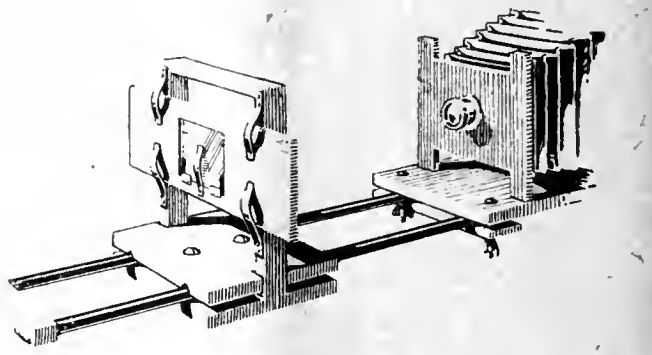
A Lantern-Slide-Making Attachment to an Enlarger.

To the half-watt enlarging installation described by me in these columns some few months ago, I have since added a detachable fitment by means of which a number of lantern-slides can be made with the greatest of ease in the minimum of time. As the construction of this arrangement is such that it can be quite well adapted to any outfit, no doubt some "B.J." readers will like to have a description of it.

It consists roughly of a pair of rails on which slides a base-board carrying an upright square frame. The latter holds, by means of flat springs, a strip of board, in the centre of which is a hole of the standard 3¼ in. by 3¼ in. The latter takes a piece of ground-glass for focussing, and when the image has been correctly focussed and centred, etc., which this apparatus renders rapid and easy, a ruby cap is put on the lens and the ground-glass replaced by a lantern-plate.

The rails are two pieces of electric-lighting conduit about 4 ft. long. At each end of these holes were drilled to allow of screwing securely to wooden cross-pieces. The base-board of the enlarger is bored with two ¼-in. holes, through which a couple of bolts are dropped. These bolts pass through similar holes in one of the cross-pieces that keep the rails together, and wing-nuts are employed for tightening up. The cross-piece at the other end is hinged to a strut of the same height as the base of the enlarger from the floor. When detached, the strut folds against the rails and the whole hangs up out of the way on a nail. The base-board and frame are built of hard wood one inch thick and about a foot in each direction. The clamping piece will be seen in the illustration and is of similar substance, and both this and the fixed base are grooved slightly to ensure alignment when sliding on the rails. A couple of bolts and nuts allow of tightening up to a nice sliding fit that will permit of easy focussing without slipping when not required to.

The plate carrier is of half-inch stuff. The hole was carefully cut just on the loose side. After one or two experiments, instead of having a rebate the aperture was cut clean through. At the lower part of each side was fixed a bit of smooth brass about an eighth of an inch thick, shown black in the sketch. These are



just over an inch long. Higher up on each side are driven in a pair of fine nails and the heads cut off. At the bottom of the hole a pair of bits of metal are screwed to prevent the slide, when placed in position, from slipping out backwards. The spring shown holding the plate is swung to one side or the other on to the wood, and then a tap on the ground-glass or the plate, as the case may be, causes the glass to lean back, but it is prevented from falling by the spring and the metal tags; at the same time the plate is easily lifted out. To insert a plate it is only necessary to push the bottom corners against the two thick brass pieces, in which operation the senses of feeling and hearing assist that of sight, and then allow the plate to drop to the bottom. A finger and thumb are sufficient both for this and for pushing the plate forward and pulling the spring over to secure it in the upright position. This procedure takes a number of words to describe, but I have done this simply to show the best way of handling the apparatus. The extension-frame of the camera projects over the rails, although this is not shown very clearly in the drawing, and I prefer to do fine-focussing by sliding the easel rather than by moving the lens.

Suitable springs can be obtained from old printing-frames, or can be purchased under the name of "drawer-springs" from the ironmonger.—D. CHARLES.

PHOTOGRAPHING MOUNT ETNA.—A curious competition in which photography is to play a part is reported from Rome. After several weeks of violent eruption the Etna volcano is very quiet, and special efforts were to be made this Easter to secure photographs of the place. Italian holiday makers were invited to spend their Easter holidays at or near Catania (Sicily), and two ships were chartered for the trip. It was proposed to make an ascent of the mountain last Sunday morning, and, according to handbills which were distributed, there was to be an opportunity for some of the tourists to be lowered into the crater of the volcano by means of a cage affair. An offer of prizes is made by the King and Queen and the Ministers for War and Instruction for those excursionists who bring back the best souvenirs, photographs and other proofs of their courage.

FORTHCOMING EXHIBITIONS.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography." Open daily from 11 to 5 p.m. 35, Russell Square, London, W.C.1.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications April 3 to 8:—

Colour Photography.—No. 9,955. Photography in two colours. O. Pfenninger.

Thermometer Stands.—No. 9,838. Stand for thermometer for recording temperature of solutions in shallow vessels. Johnson & Sons, Manufacturing Chemists, Ltd.

Apparatus.—No. 10,022. Apparatus for photographing or projecting images. H. H. and S. H. Mears.

Apparatus.—No. 10,086. Photographing apparatus. J. Pecso.

Projection Apparatus.—No. 9,870. Apparatus for direct-vision or projection of separate transparent photographic views upon films, etc. H. de Ruyter.

Reproduction Method.—No. 9,953. Mechanically reproducing portraits, models, etc., from stereoscopic photographs. E. E. Townsend.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Vertical Self-focussing Enlargers. No. 156,515 (February 6, 1918). The invention relates to automatically-focussing projection apparatus of the kind described in Patent No. 156,224, and has for its object to provide means whereby such apparatus can be used with lenses of different focal lengths, the lens being held in optical co-relation with the object plane and the image plane of the apparatus automatically whatever the degree of enlargement. The pinion or other member by means of which the lens board is moved relatively to the negative upon the camera support has a slotted arm mounted upon it in adjustable operative relation thereto. The slot in the arm is so curved and engaged by an adjustable lever on one of the swinging links carrying the camera support that as the support is moved towards or away from the screen or image plane the correct focus of the lens is automatically secured after the slotted arm has been initially set. Thus by varying the relative position of the slotted arm upon the driving pinion and by simultaneously varying the effective length of the lever engaging the slotted arm it is possible to secure automatic focussing whatever the focal length of the lens and without having to provide an interchangeable slotted arm as hitherto.

In the drawings, the camera 1 is mounted upon arms 2

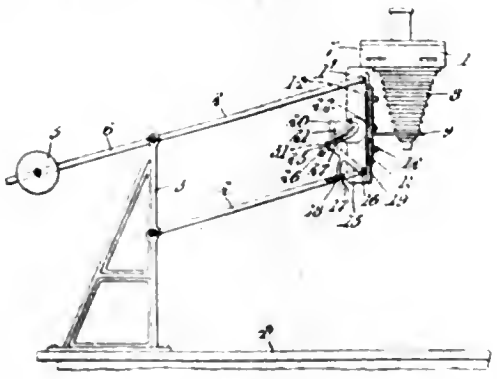


Fig. 1.

pivoted for movement in a vertical plane on to a frame or support 3 which may be attached to the wall, or, as indicated, mounted upon a table 4. One of the arms 2 may be extended as at 6, and provided with a counterweight 5 to balance the weight of the camera and other mechanism carried by the arms 2. The arms 2, together with the frame 3, and camera support 1^1, constitute a parallel link system so that the camera always moves in a plane at right angles to the projection screen or table 4.

The enlarging camera of the outfit comprises the usual box or frame 7 rigidly connected to the support 1^1, and is provided with bellows 8, terminating in a lens board 9 mounted on a carrier 11. Mounted to slide upon the support 1^1 is a bar 10, carrying a rack 14, the bar being adjustably attached to the carrier by means of set screws 12 extending through enlongated slots 13 formed in the carrier. Adjustably connected to the lower arm 2 is a lever 15 which is free to turn about its pivot 16, but is provided with a quadrantal arm 17 formed integral therewith, locked in the position of adjustment by means of a set screw 18. Thus the arm or lever 15 can be held at the required angle to the pivoted arm 2.

On the support 1^1 is mounted with a pivot 20^1 a plate 20

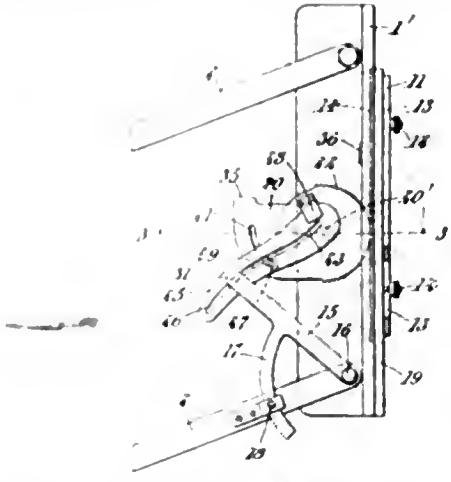

Fig. 2

having a curved slot 21 and a semi-circular portion provided with teeth 22 to engage the rack 14, the whole constituting a driving member for the rack. The plate 20 also carries a short stud 23 eccentrically mounted thereon. An arm 25 having a cam slot 26 engages the stud 23 and carries a pin 27 to engage the curved slot 21. Suitable means such as a spring plate 28 secured to the face of the plate 20 may be provided to hold the arm 25 and plate 20 against lateral separation while at the

same time admitting relative sliding movement in the plane of contact.

The pin 27 has a screw-threaded extension engaged by a nut 29 so that the arm 25 and the plate 20 can be locked together, the slotted arm then constituting a lever for turning the complete or partial pinion 22 to engage the rack. Mounted on the lever 15, near its free end, is a stud 31 adapted to engage the cam slot 26, the studs 23 and 31 and the arm 25 being so related that there is no interference between the studs during their movement in the cam slot 26. The bar 10 preferably has grooves 10^1 engaging ribs on guides 19, which may be secured to the support 1^1 in any suitable way, as, for instance, by screws 19^1.

The operation of the apparatus is as follows:—Assuming that the focal length of the lens is unknown the mechanism is set by loosening the clamping screw 18 and moving the whole apparatus into a low position. The lever 15

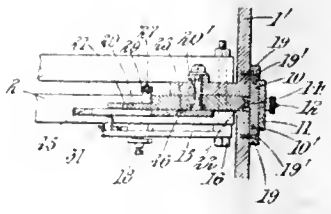

Fig. 3.

is then thrown over as far as possible to the right so that the point 35 on the plate 20 makes contact with the stop 36 on the support 1^1. With these two points in contact the projected image is focussed sharply at 1½ in. diameters magnification on to the table used as the projection screen. While the parts still occupy this position the set screws 12 and 18 are tightened whereupon the pivoted arms 2, together with the camera support, are pushed upwards a considerable distance above the screen, and the nut 29 on the stud 27 is loosened while the set screws 12 and 18 remain clamped. The sliding bar 10 is then adjusted until a sharp image is again obtained, and by so manipulating the bar the teeth on the driving member 20 by engaging the rack 14 bring about a definite angular adjustment on the driving member about its pivot. At the same time the slotted arm 25, by engagement of the stud 27 in its slot 21, is made to occupy a definite position relatively to the driving member 20.

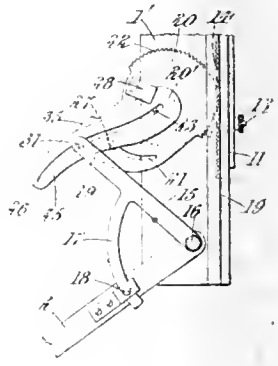

Fig. 4.

The nut 29 is then suitably tightened to lock the arm 25 and driving member 20 together, and the apparatus is then set to obtain absolutely sharp focus for any enlargement between 1½ in. to 18 in. diameter when using a lens of approximately 7½ in. focus. The form of the cam slot 26, as computed or experimentally determined for a particular lens, depends upon the length of the arms 2, the length of the lever 15 and the radius of the pinion forming part of the driving member 20.

It has been found that the cam slot designed for the longest focal length lens to be used may be used for any shorter focus lens by shifting the position of this cam slot relatively to its support and that for each lens there is one definite position in which the cam slot operates for the purpose specified. By providing means such as the curved slot 21 in the plate 20 and the stud 27 on the arm 25, the cam slot is forced to undergo such movement relatively to its supporting plate 20 that its successive positions correspond to lenses of successive varying focal lengths. The cam slot 21 is designed to cover a particular range of lens powers ordinarily met with in practice being available for use with lenses having a focal length of from 4 to 10 in. It is to be understood that there is no definite limit to the range, and the cam slot 26 illustrated is designed to admit of a magnification of 1½ in. diameters as its lower limit. Figs. 2 and 4 show, by way of comparison, the two extreme adjustments, fig. 2 illustrating the device set for a lens of approximately 5 in. focus, while fig. 4 shows the adjustment for a lens of 10 in. focus. As can be easily ascertained from the drawings, the rate of movement of the bar in the case of fig. 2 will be much less than in the case of the setting illustrated in fig. 4 for the same angular movement of the arms 2. Kodak, Ltd., Kodak House, Kingsway, London, W.C., assignees of Roy Samuel Hopkins, 1221½, Market Street, Parkersburg, W. Va., United States.

The following complete specifications are open to public inspection before acceptance:—

Films.—No. 177,805. Method of and means for securing a length or strip of photographic film in a flat coil in a condition suitable for treatment by liquid. Correxmuvek Filmipari Gepgyar C. Lazzlo.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Apem.—No. 419,775. All goods included in class 1. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers. October 21, 1921.

Apem.—No. 419,776. All goods included in class 8. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers. October 21, 1921.

Apem.—No. 419,777. All goods included in class 13, but not including needles or fasteners for collars, and not including any goods of a like kind to any of these excluded goods. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers. October 21, 1921.

New Apparatus.

The Apem Reflex Camera. Made by Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1.

In this camera we have the first fruits which have come under our notice of the enterprise which the Kershaw branch of the A.P.M. has undertaken, namely, the manufacture on a scale permitting of popular prices of cameras for the amateur photographer. The fact that it has been found possible to place upon the market a quarter-plate reflex camera with three single metal plate-holders and an *f*/5.9 6-inch lens at the price of £10 10s. is sufficient evidence of the success which has followed the specialised organisation of this company in camera manufacture.

As makers for many years of the Soho reflex, Messrs. Kershaw can claim perhaps a unique experience in this country in the manufacture of this particular type of camera. It is not claimed that the present model represents refinements of design and inclusion of details which have made the Soho as reliable and efficient a reflex as any to be bought. Nevertheless, the Apem reflex, which we have had through our hands during the last week or two, is a thoroughly reliable instrument, and, moreover, one which pays due regard to the considerations which are of most practical importance in the successful use of a reflex. The camera is of the single extension type, excellently rigid with the lens front at its maximum distance of about 8½ inches from the plate. It can be used with certain lenses of as short a focal length as 5⅜ inches, while as regards the needs of those photographers requiring a long focus, it is easy to fit one or other of the fixed-focus telephoto lenses, giving an

equivalent focal length about 1½ to 2 times the camera extension. The introduction of these lenses, of aperture from about f/5 to f/8, may be said to have disposed of the necessity of a double extension in a reflex, or, in fact, any other hand-camera. The lens front of the Apem has nearly 1 inch rise and ½ inch fall, and the lens itself is provided with a cover of ample size, which automatically springs up when released and then forms a sky shade. The hood is of good design, 6¾ inches high, and affords a clear view of the focussing screen. We are glad to see that the makers have made the focussing screen instantly accessible for dusting. In our considerable experience with a reflex camera, this is one of the movements that is most frequently required. In carrying about a camera throughout the day the settling of dust on the focussing screen is the chief cause of any difficulty there may be in the sharpest focussing. In the Apem the focussing screen itself is also quickly removable, giving access to the mirror for the dusting which, in its case, is much less frequently necessary.

The mirror is one of the self-falling variety, but remarkably smooth in action and requiring a very much lighter pressure to raise

it than many in cameras of this type which we have used. Reversing of the plate (into the horizontal or upright position) is obtained by means of a detachable square back.

The focal-plane shutter has a quite quick enough wind, is adjustable for time exposures and is fitted with the old, but simple and reliable, method of adjusting the width of slit, consisting in operating a cord which draws two ends of the blind together or allows of their being extended. Although this method of slit adjustment is slower than that of more modern types of shutter, we would as soon have it as any on account of the less complicated construction of shutter which it permits. In finish the camera is of good appearance, covered in black leather cloth, with most of its metal parts of semi-glossy black finish. Without lens, but including three single metal-holders, its price is £9 9s. At £10 10s. it is fitted with an f/5.9 Wray Lustrar, whilst other lenses may be fitted up to a price of £21 15s., which is the figure for the camera fitted with a Ross f/4.5 Xpres.

Developing and Fixing Tanks.—Messrs. Otter-Judge & Co., 45-47, Rudyard Road, Sheffield, offer a set of vertical developing, fixing, and washing tanks, which have many of the special qualities demanded of such articles. The tanks are made of 22-gauge lead, tested for leakage, and are then sunk—by a special process—in a case of selected seasoned timber. The case is cemented with an impervious cement, and is itself water-tight. The inside dimensions are 42 in. x 9 in. x 8½ in.; capacity, 10½ gallons; developing 250 spools in one bath. The developing tank and fixing tanks are fitted with brass taps; the washing tank can be fitted with a syphon tube of small or large diameter, as required for slow or rapid outflow. Although strongly made the tanks are quite portable—weight about 56 lbs.—and are well designed. The bottom of the tank is protected by prolongation of the sides, and the whole constructions is such that accidental breakage is impossible. The lead lining deserves special mention; the makers experienced difficulty in securing a suitable lead, but persevered until they obtained one with a remarkably smooth surface, and the tank submitted for our inspection left nothing to be desired in this respect. The tanks are listed at £9 9s. per set of three, complete and carriage forward, and the makers are prepared to quote for other sizes.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday April 11. The president, Mr. W. I. F. Wastell, in the chair.

Dr. Henry B. Goodwin, of Stockholm, delivered a lecture entitled "Photographic Portraiture, Pure and Simple." It was an outspoken expression of his views on the recent tendencies in photographic portraiture and figure-study work. Although a member of the London Salon, Dr. Goodwin strongly dissents from a large part of the policy which is reflected each year in the exhibition, and, it would seem still more so from the choice of examples of pictorial photography which find a place in "Photograms of the Year." He dwelt emphatically upon the baneful effect of those pictorialists who have shown great theatricality in their work. While not exactly saddling the late Rudolph Duhrkoop with the genesis of this school, he was inclined to attribute the straining after theatrical effect to a misunderstanding of the misconceptions of Duhrkoop. The gist of his criticism was applied first to the kind of thing he called "theatrogram," a rendering of an actress, dancer, or cinema star, the characteristics of which were created in the subject, and owed nothing to the photographer's discernment and interpretation of natural beauty. They were simply stages, made up productions, the output of a mind exclusively concentrated upon style.

He quoted Mr. Herbert Lambert's definition of simple portraiture, namely, one which produced a certain feeling of rightness and inevitability, and he showed in contrast therewith some specimens of modern "theatrograms," another name for which he had coined viz. "choreographic arms." Another modern vogue which came under his criticism was "adulterated portraiture," quasi-portraits, but adulterated by fancy lighting, stagey posing, loud

backgrounds, or all of them together. Dr. Goodwin showed some examples of the way in which all character rendering had disappeared from the portraits of several sitters of note by indulgence in these methods; on the other hand, he had a few examples to show of works of artistic simplicity by Luboshez, Madame d'Ora, Pirie Macdonald, and Nicola Perscheid. The last-named had been a great benefactor and friend to some photographers in Scandinavia by his lectures and courses of lessons.

He urged that the portrait photograph should emulate the well-written story as distinguished from a police-court report. Future generations would expect photographs to be reliable human documents, revealing the characteristic look of the personality. Yet the works of fashionable portrait photographers fell infinitely below this aim. Dr. Goodwin instanced a portrait of Jenny Hasselqvist, the greatest Scandinavian dancer, made in London, and largely published, which utterly failed in rendering the extraordinary psychic and physical beauty of her face. The remedy for the harm which was being done to photography by the spurious works of the ignorant and the arrogant was a return to the study of nature and the study of life.

A discussion followed, in which Messrs. Herbert Lambert, F. C. Tilney, Marcus Adams, Dudley Johnstone, W. Thomas and the chairman took part, and a most hearty and appreciative vote of thanks was accorded to Dr. Goodwin by acclamation.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

The members of the Society assembled at the studio of Mr. Percy Guttenberg, 40, Oxford Street, Manchester, on April 5, by kind invitation of the proprietor. The proceedings opened with a short business meeting, which was presided over by Mr. Arthur Winter, president of the Society.

The secretary reported that at the committee meeting held that day arrangements had been made to hold an exhibition of photographs in conjunction with the Trades' Exhibition to be held at Blackpool on May 15 to 20, and a sub-committee had been appointed to take charge of the same.

The date of the annual meeting was fixed for May 17, and the trade dinner will be held on the evening of the same day. During the run of the exhibition several demonstrations will be given. Particulars of these will be fully reported at a later date.

The secretary reported that a number of new members had joined the Society since the last meeting, and the treasurer's report was a very satisfactory one.

The president (Mr. Arthur Winter) stated that Mr. Lang Sims was honouring them by a visit, and he introduced him to the members. Mr. Lang Sims stated that he felt honoured to be given the privilege of saying a few words to them, and would like to take the opportunity of explaining his position with regard to the P.P.A. As was well known, he had recently resigned his position as secretary, but he would like it to be distinctly understood that he was on the best of terms with the Council, and he had been unanimously elected a member of that body. His object in visiting Manchester was to meet as many members as possible of the P.P.A., and to ask for their support for the Conference which will be held in London in the month of September. He had been associated with the P.P.A. from its very inception, and had seen a number of local societies come and go, but he congratulated the Society of Master Photographers on being the only local society that had lived. He did not think that they had in any way interfered with the work of the P.P.A., as their organisation was a purely local one, whereas the P.P.A. was national, and he knew that a large percentage of their members were also members of the P.P.A.

He was pleased to inform them that very shortly the P.P.A. would be in a position to issue a monthly journal, and, should the Society desire any assistance so far as that journal was concerned, he felt certain the Council would be only too pleased to help them. He hoped that the members of the Society would do their best to arrange to be present at the Congress in September, as it would be purely of a professional nature, and they hoped to have an international exhibition, which would be of great interest to every professional photographer. He thanked them for the kindly welcome that they had given him. It was the first opportunity he had had of meeting the members of the Society, and he hoped at some future date to renew their acquaintance.

The president, in thanking Mr. Lang Sims for the information he had given with regard to the Congress, promised that the members would support the P.P.A. in every way possible. He then called upon Mr. Percy Guttenberg to give his address on "How to Conduct the Modern Studio."

Mr. Guttenberg stated that in considering the question of "How to Conduct a Studio" he would start from the window or showcase, and impress upon the professional photographer the necessity of giving these his close attention. He called attention to his own window, which was illuminated with very bright lights, and he took advantage of every opportunity to make a good show at night. The lights in his window were so arranged that they not only illuminated the sign in the window, but helped to light the reception room. The lights were hidden from view, and the window was always attractive. In his opinion, the specimens in the window should be frequently changed, and he thought it a good idea to have specimen prints done at the same time as the customer's order; if not, they were never done. This would give a ready supply of fresh prints. So far as his window was concerned, it was changed daily, not necessarily with new specimens, but the positions of the specimens in the window were altered.

With regard to the question of dealing with customers, more often than not people come in and say, "I don't know what I want." This is the opportunity for the receptionist. His personal experience was, the fewer specimens you submit the more successful you are in getting the best out of your customer. This was a "golden rule" in every business. They should begin by showing the most expensive, and only go slowly to the cheaper ones. When people call in to make an appointment, and not to sit immediately, reverse the order of things, and show them the cheapest styles, trusting to do better when they come for their sitting.

Proceeding to describe his business methods, Mr. Guttenberg said:—

"We keep an appointment book, and an appointment card is given in each case. Nearly the whole of our orders are cash at the time of sitting, or, in the case of copies or enlargements, the time of ordering. All enlargements are quoted without frames; by so doing it lessens the first cost. When sending a written quotation for enlarged portraits, send measurements of actual picture only. Point this out distinctly, because if it is in competition someone else may include outside edge of mount, and, in consequence, the other quotation may appear better value.

"Each of our customers has a registered number. This number is quoted on the negative, and on all correspondence, etc. For reference we also keep a 'reminder book,' which is dated, and all special orders or promises are entered into it.

"A ticket is given to the operator with a registered number on and particulars of order. This number is put on the plates, and any details that the clients may ask the operator in regard to proofs or otherwise is referred to the receptionist, a telephone being fixed from the reception room to the studio. The negatives, when developed, are sent upstairs each morning for naming and numbering. Retouched, but light and unfinished, proofs are always posted in from six to seven days, and, when returned, are marked on the back with the number required. The date of the return of proofs is also entered with the original order. This saves any disputes. We take about sixteen days to complete, but we are in a position to complete one dozen 11 × 7 sketch portraits in twelve hours if absolutely necessary.

"Our work is mostly called for if within reasonable distance, and our customers are advised when they are ready. The saving of postage by this means is very great, and sometimes leads to other business, as the oftener you can bring your client to the studio, the better. All proofs and orders are sent to the works at 5 p.m., and are passed through a duplicating book, and the order sheets are returned with the complete work. No verbal orders are permitted or given, and there is no saying, 'You said this' or 'I said that.' We keep a negative register, which is most necessary to trace up negatives for re-orders, or to see from the books what the clients had previously. This is also a general guide as to all previous transactions.

"My works are connected by a private telephone, and are only a few minutes away; it is there we do all paintings, printings, retouchings, and mounting, etc.

"My books are kept by chartered accountants, who attend on

the seventh day in each month, to write up all accounts. A balance-sheet and profit and loss account is prepared each year, so that we can see at a glance what has been spent on rent, rates, salaries, mounts, plates, postages, etc., and we compare and correct or stop if there is an undue increase. I pay all my accounts on the 28th of each month, and never lose a discount, and it is surprising what these discounts mean and amount to.

"The studios are open from 9 to 6, Saturdays 9 to 1. Punctuality in opening and closing are of vital importance, and I am most particular as to this. We have a contract for the cleaning of windows, which is done every morning outside and twice a week inside, but is dusted inside twice a day. We keep two cleaners, and they are always busy attending to some portion or other of the premises.

"I draw your attention to the fact that you will not see any accumulation of old accessories or frames or rejected negatives, as I scrap anything that is useless, and replace immediately any plant that can be bettered. In conclusion, I would like to say a word about invitation sittings. I feel very keenly about this, and so did my father. He commenced business in Bristol in 1845. We have thus been established 77 years, 45 of which has been in Manchester, and I can thus claim to be one of the oldest firms in the profession. I am very proud of that fact, and can honestly say that, as far as I know, and certainly not in the last 30 years that I have been in business, we have never given an invitation sitting, so much so, that the photographs taken of the King and Queen, the Prince of Wales, etc., were ordered and paid for by the city. If the members of the trade would abolish invitation sittings, it would add greatly to the dignity of the profession of photography."

During the evening Mr. Guttenberg gave a demonstration of posing and lighting by artificial light. His studio is so arranged that lighting effects can be demonstrated in any part of it, the result being that backgrounds are dispensed with and different sections of the studio are utilised in place of them.

The exposures were made on flat Eastman films, as Mr Guttenberg uses nothing else in his studio.

Several prominent members of the Society acted as models, and specimens of the results were shown to members before the close of the meeting.

Mr. Percy Guttenberg concluded his address by stating that he had for the past 27 years been greatly indebted to his wife for the great assistance she had been to him in his business, and they had been true partners all through their married life.

At the conclusion of Mr. Guttenberg's address, Mr. Fred Read proposed a vote of thanks to Mr. Guttenberg for his address, and to Mr. Lang Sims for his remarks with regard to the P.P.A.

Mr. N. S. Kay seconded the vote of thanks, and it was carried unanimously.

The President called upon Mr. Lang Sims to reply on behalf of himself and Mr. Guttenberg, and Mr. Lang Sims having suitably replied, a most successful meeting held by the Society terminated.

CROYDON CAMERA CLUB.

Kindly changing dates with Mr. Reynolds (billed for "Colour Vision"), Mr. J. W. Purkis, at short notice, discoursed on "Platinotype in a Test Tube," and succeeded in bringing home to the least scientific of his audience the main principles underlying the process.

To follow the lecturer through the instructive experiments conducted, and allude to the results of others passed round, would involve a treatise on the subject, and will not be attempted. Very clearly he explained that platinotype paper is coated with two salts, one a salt of platinum, which is practically insensitive to light, and the other a light-sensitive iron salt, which on exposure to daylight undergoes a definite and visible chemical change, being converted from the ferric to the ferrous state. The initial iron picture thus formed in the act of dissolving in the developer reduces *in situ* the platinum salt to metal proportionally to the original light-action. The residuum of salts left in the paper is removed by weak acid baths, and a short wash completes operations.

Quite a feat was the preparation of a sheet of platinum paper; its exposure behind a clear-glass thin negative to ignited magnesium ribbon, and the production of a print all well within ten minutes. Not an inexpensive experiment either, with a 15 gr. tube of the platinum salt priced at 7s. 6d. In point of "quality" the print left something to be desired.

This led Mr. Purkis to emphasise the fact that a wide gulf yawned between laboratory experiments and the high-grade commercial article of consistent uniformity. In his opinion far too little recognition was afforded the men who by scientific methods patiently and laboriously evolved the many almost perfect products of the present day.

In the discussion the first blast from Mr. Harpur woke up with a start an elderly visitor who had peacefully dropped off to sleep. Mr. Harpur made various suggestions for improvement in platinotype procedures, which at least possessed the merit of originality. The vapour from a bottle of hydrochloric acid, accidentally left unstoppered, combined with an equally fragrant drift from the president's cigar having reached the secretary's nostrils, here caused a momentary change of subject. Next came a consideration of the respective advantages of rubber pads, American cloth, celluloid, oil-silk and old sausage skins as damp-proof backing for the paper during printing, the balance of opinion being in favour of the first-named.

Mr. Salt congratulated the lecturer on an admirable exposition out of the ordinary rut; chided him for calling the clearing baths "fixing baths," and pointed out that although the paper should be kept dry in all stages, only reasonable precautions were demanded. Paper, however, required to be stored, i.e., should not be allowed to absorb damp. A most hearty vote of thanks was accorded Mr. Purkis for a lecture which must have involved much preparation.

Commercial & Legal Intelligence.

LEGAL NOTICES. Notice is given, pursuant to Section 242 (3) of the Companies (Consolidation) Act, 1908, that, at the expiration of three months from April 11, the names of the undermentioned companies will, unless cause is shown to the contrary, be struck off the Register of Joint Stock Companies, and the companies will be dissolved:—Essex Photographics, Ltd.; Keystone Art Company, Ltd; Life Portraits, Ltd.

NEW COMPANIES.

E. GOULD & SON, LTD.—This private company was registered on April 5, with a capital of £100 in £1 shares. Objects: To carry on the business of chemists, druggists, photographers, etc. The provisional directors are: J. S. Stooke-Vaughan, 12, John Street, Bedford Row, W.C., solicitor; A. Wilson, Bourne Farm, Bexley, Kent, secretary. Registered office: 35, Moorgate Street, E.C.2.

OPTEX, LTD.—This private company was registered on April 6, with a capital of £100 in £1 shares. Objects: To carry on the business of opticians and makers of photographic appliances, etc. The first directors are: T. Edwards, 233-5, Queen's Road, Battersea, S.W.8, manufacturer; H. R. Herbert, 126, Barry Road, S.E.22, merchant. Secretary (*pro tem.*): H. R. Herbert. Registered office: 45 and 46, King Street, Cheapside, E.C.

GRAPHIC ENGRAVERS, LTD.—This private company was registered on April 6, with a capital of £2,000 in £1 shares (1,000 ordinary and 1,000 preference). Objects: To carry on the business of engravers of photographic or any other process, etc. The subscribers (each with one share) are: G. T. Cooke, 22, Broad Street, Bristol, solicitor; O. G. Cooke, 22, Broad Street, Bristol, solicitor. The subscribers are to appoint the first directors. Secretary: J. W. Corrigan. Registered office: Westown House, Brislington, Bristol.

GEORGE E. GIBSON, LTD.—This private company was registered on April 6, with a capital of £1,000 in £1 shares. Objects: To take over the business of a chemist formerly carried on by G. E. Gibson at 359, Portswood Road, Southampton, and to carry on the business of dealers in photographic supplies, etc. The first directors are: A. E. Popplestone (governing director), 55, St. Denys Road, Southampton; Mrs. Alice M. Popplestone, 55, St. Denys Road, Southampton; S. E. W. Martin, 89, Bullar Road, Southampton. Qualification: One share. Registered office: 359, Portswood Road, Southampton.

CLARENDON CHEMICAL CO., LTD.—This private company was registered on April 6, with a capital of £1,500 in 1,000 "A" shares of £1 each and 10,000 "B" shares of 1s. each. Objects: To carry on the business of chemical and drug manufacturers, manufacturers of and dealers in photographic apparatus, etc. The first directors are:

E. Todd, no address stated; J. K. Watson, Wivelsfield, 116, Kew Road, Richmond, Surrey; T. H. Forteath, no address stated; E. Cohen, Finsbury House, Blomfield Street, E.C. Qualification: One "A" or one "B" share. Remuneration: £250 each per annum (chairman, £100 extra), free of income tax up to 6s. in the £. Registered office: Finsbury House, Blomfield Street, E.C.

News and Notes.

STOLEN CAMERAS.—Several binoculars and cameras, valued at £140, were stolen during the week-end from a house in East Dulwich by thieves, who entered the house by breaking the glass of the fanlight.

ROYAL INSTITUTION.—On Thursday (April 27) Professor E. H. Barton delivers the first of two lectures on (I.) "The Resonance Theory of Audition"; (II.) "A Syntonic Hypothesis of Colour Vision."

CAMERA SMUGGLING AGAIN.—For smuggling four watches, a camera and parts of cameras, the Dover magistrates last Saturday imposed a fine of £134 on a Japanese Channel passenger, stated to be director of a company.

THE CAMERA EXPLAINS RELATIVITY.—A Reuter telegram from Berlin announces the publication of a trick film, 9,000 feet long, to illustrate the Einstein theory. The photographic work has taken six months to perfect, and the object of the picture is to make clear to the lay mind various facts in the domain of physics and light which lie at the root of the relativity theory.

THE BRIGHTON POST OFFICE CAMERA CLUB has recently been formed, and the thirty-eight members are mostly beginners. Under the guidance of Mr. A. Deane, the Club is concentrating on the elementary processes of negative making and printing. A convenient dark-room fitted with a ½-pl. enlarger and accessories has been provided for the use of members. The Honorary Secretary is Mr. Albert Gill, 35, Stanford Road, Brighton.

RACE TRAFFIC PHOTOGRAPHS.—Last year, it may be remembered, a large series of photographs was taken from the air of the traffic going to the "Derby" and other races at Epsom. The authorities now state that such pictures have enabled them to remodel many traffic regulations and to make many improvements in the diversion of traffic at the numerous cross roads where congestion occurred. Aerial photographs will again be taken of any congestion *en route* as well as progress of the traffic at specific times before and after the races.

SIR ROSS SMITH AND PHOTOGRAPHY.—Sir Ross Smith, who was killed at Brooklands last Thursday in an aeroplane accident, played an important part in aerial photography during the war in Palestine. At one time (the "Daily Telegraph" states) the British advance upon Jerusalem was held up by difficult country. The old maps were of very little use, and the Air Service had to prepare new ones. An order was issued one night, and the next day two Australians, Lieut. (later Sir) Ross Smith and Lieut. Austin, photographed from the air an area of thirty-seven square miles, the work enabling the staff to organise an advance, and five days later our troops had driven the Turks from the precincts of the Holy City.

FLASHLIGHT PHOTOGRAPHY FETCHES FIRE BRIGADE.—The taking of flashlight photographs in a warehouse in London Wall last week resulted in a false alarm of fire and the appearance of six engines and escapes. A similar incident occurred at a flashlight demonstration given at the old London and Provincial Photographic Association about twenty-five years ago (writes a correspondent). A kindly-disposed passer-by seeing the brilliant light and the smoke —and there was smoke from magnesium in those days—gave the alarm, and in a few minutes the harmony of the meeting, as well as the demonstrator's discourse on the advantages of flashlight, was interrupted by the rattle of fire engines outside and the appearance of firemen at the door.

PHOTOGRAPHY OF FASHIONS AND MODELS.—A correspondent who was particularly interested in our recent article on "The Problem of the Model," sends us some extracts from a special article which appeared in last Saturday's "Daily Telegraph." The writer of the article had the cinematograph camera in mind when penning the note, but his remarks apply equally well to the ordinary camera. In the article it is stated that announcement has been made of a more extended use of the cinematograph for the purpose of displaying the latest models in dress as they appear in wear. The idea is put forward as a novelty, and as showing the developments of the practical application of the film to everyday requirements. But the suggestion is hardly as new as is claimed. It has been tried in connection with exhibitions dealing with fashions, and it has been found wanting in at least two highly important directions. Colour, in the first place, cannot be shown to any appreciable extent in this way, and every woman knows the part that is played in the success of a toilette by having the correct and appropriate tones, whether of the material itself or the accessories in trimmings and embroideries, into which harmonies and contrast are effectively introduced. Again, the film cannot convey the right sense of the texture of the material employed. A cheap muslin and a costly crêpe marocain, a rich velvet or a mere shoddy tweed, would present little difference on the screen.

Correspondence.

PORTRAITS AND THEATROGRAMS.

To the Editors.

Gentlemen,—I was present at Dr. Goodwin's lecture, but could not agree with all he said. Portraits and "theatrograms" are not the same thing, so you cannot judge them in the same way. Chiffon and velvet are both materials and each is good of its kind, but chiffon velvet is both, and is perhaps more beautiful.

Last week at Mr. Lambert's lecture we had two slides of Rodin: the first a bad portrait, the second a very fine "theatrogram." The one photographer "played" (?) with his light to a much greater advantage than the other used his 45 degrees. The best of all portraits are also theatrograms; they are thoughtfully staged to emphasise the personality of the sitter.—Yours,

MAUD BASIL.

100, Tottenham Court Road, London.

THE "R.P.S.": ITS EARLIEST TROUBLES.

To the Editors.

Gentlemen.—Your editorial note on the many flittings of the (now) Royal Photographic Society reminds me of some of its earliest troubles, difficulties, curiously enough, brought about by the (now) "B.J.," and also Fox Talbot, to whom the Society is to institute a memorial. The story was told me some years ago by an octogenarian photographic celebrity who knew all concerned, and your pages are, I consider, a suitable place to record some curious facts not generally known.

Roger Fenton was, it is believed, the real founder of the Society; he was its first hon. secretary, and it was he who got together a few workers to discuss the matter, the meeting being held during the winter of 1850 at the offices of "The Art Journal," a publication which was then paying photography particular attention. This initial attempt to form a society was a failure, though many of the enthusiasts continued to meet, as they had been meeting, unofficially and without rules.

The reason of the failure makes curious reading to-day. It was due to the existence of certain patent rights held by Fox Talbot, rights exercised in such a way as to preclude all hope of forming a really good society. The enthusiasts took no further steps until 1852, when a deputation was appointed to bring pressure to bear on Fox Talbot. The deputation was a very influential one, Sir Charles Eastlake, president of the Royal Academy (and afterwards

first president of the Photographic Society), playing a prominent part; another member of the depntation was Lord Rosse, president of the Royal Society. To the deputation, and particularly to the two gentlemen named, do we owe the partial waiver by Fox Talbot of his rights or claims, and the foundation of the Photographic Society of London, which afterwards (1874) became the Photographic Society of Great Britain, and later (1894) the Royal Photographic Society.

The inaugural meeting was called by advertisement in the leading newspapers for January 20, 1853, and it was held at the Society of Arts. At the end of the first year the number of members was 370, and the receipts £645. The first exhibition of pictures was held in January, 1854, and was visited by Queen Victoria and Prince Albert.

Another little known fact is that concerning the clashing of the Society's "Journal" with your own. The Society brought out the first issue of its journal—called "The Photographic Journal"—on March 3, 1853, and its circulation grew rapidly to 4 000. Then in 1859 the Liverpool and Manchester "Photographic Journal" (which started in 1854) came to London, dropped the names of Liverpool and Manchester from its title, and came out as "The Photographic Journal." Naturally there was trouble and legal proceedings were taken, a Mr. Bohn being appointed arbitrator. The latter decided in favour of the Photographic Society, and your journal, as you no doubt know, was compelled to find a new name—the one it bears to-day.

Most of the facts recorded above are probably well known to the older generation of your readers, but I have an idea that the story of the Fox Talbot trouble will be new to them.—Yours faithfully,

G. W. B.

PERMANGANATE FOR HYDROQUINONE STAINS.

To the Editors.

Gentlemen,—While I can endorse all you say in last week's "B. J." (p. 224) concerning the removal of hydroquinone stains by means of the Ilford solution, I would like to point out that slight stains, particularly upon lantern plates, may be removed by use of a plain but very weak solution of permanganate alone.

Many years ago, when visiting the Paget Works at Watford, I witnessed the making of some lantern slides by their expert, Mr. W. J. Wilson. A hydroquinone developer was used, and there was a brownish stain over some of the high-lights of the slides, and on my commenting upon this defect, Mr. Wilson took a few grains of permanganate and dissolved them in water so as to make a light pink solution; the slides were then immersed in the solution for a few minutes, when the stain vanished, he telling me that the dodge was then not generally known.

On many occasions since that demonstration I have removed slight brownish (hydroquinone) stains from slides in a like manner, also from negatives, but stains upon the latter always appear to be more deeply embedded, and more difficult to remove, than stains on slides. Anyway, the remedy is simple and cheap enough and well worth a trial, but care must be taken to have the solution weak, and certainly not of a deep, or even a medium, pink colour.—Yours faithfully,

S. T. RAWNHAM.

PRESENT-DAY TECHNICAL QUALITY.

To the Editors.

Gentlemen,—In your "Ex Cathedra" Notes of March 10 there is a short article on fixing bath for bromides, which, if carefully followed, would be valuable for those who desire good technical quality and colour in their negatives.

But meanwhile let me say that I consider your leader on the above subject very stimulating for those, like myself, who win their daily bread by photography. It is hard to say what Dr. Glover means by the school to which he belongs. If he is writing for a few select aristocrats, well and good; he has every freedom to do so, but the great majority of photographers would not understand him. If he is to use his ability and learning for the profession he will have to come down a good bit before he can uplift those benighted men who are in the desert with stickybacks and postcards. Certainly Dr. Glover has a marvellous way of expressing a simple fact. In his own language, "The magnitude of the range of light-intensities." Now the blocks in my school would "sling their lamps" on clear glass and good or full density, and say, "Here, Alf, print this negative on any paper you please!" Of course, Dr. Glover will excuse these vulgarisms, because they were suggested by his own letter, and because I was brought up in a school that had only one plate, one developer and one printing paper.

If a negative was thin in those days they brought it up with a few drops of silver and iron to standard strength, and I don't think that they will invent any instrument to beat a good human eye at judging density.—Yours faithfully,

HENRY HOLMAN.

Banff.

To the Editors.

Gentlemen,—Your leader of the 7th, and Dr. Glover's commentary, illustrate the difference between practice and theory, a difference which can only be appreciated by those who depend on practice for their daily bread. While not ignorant of the theoretical facts expounded by Dr. Glover, I agree with your views, and I do so because I have lived photography all day and every day for a good many years. I don't think Dr. Glover can say this; if he could, he wouldn't be a doctor.

He asks, "Can it be seriously suggested that a negative can be so excellent that it will both yield a good print on vigorous gaslight paper and P.O.P.?" Well, what is wonderful about it? Years ago I used a vigorous P.O.P. for thin, soft negatives, and a soft P.O.P. for harsh negatives, and they were equal to any gaslight papers. And why does Dr. Glover say *gaslight?* Perhaps he would be surprised to know that in trying to make pictures for the public from bits of clear celluloid I use *bromide*, not gaslight, and I do not find a want of vigour.

The P.O.P.s mentioned were supplied by Messrs. Griffin and Messrs. Rajar respectively. I cannot say whether they are still obtainable, but grades of vigour are not monopolised by gaslight paper. Had the question been: Can a negative be so excellent as to render good prints from gaslight, bromide, P.O.P., platinum or carbon, without any mention of "vigorous"? I should say that it did not require to be excellent; it only needed to be of the old professional average to do all that.—Yours sincerely,

31, August Road, Liverpool. J. R. HALL.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—Mr. Bierman's note on "System in Half-Tone Operating" raises some interesting points, and I should like to contribute a few notes on his ideal and the two systems which he criticises. Mr. Bierman's ideal is evidently, and quite soundly, based on the scientific and practical principle that the system which involves the alteration of the smallest number of factors is best, unless very great advantages can be proved to result from more complicated methods.

While a system must be very bad before it is equal to no system at all, the Douthitt System seems to depart very far from the ideal stated above, and, in doing so, introduces other objections. Taking the figures given by Mr. Grenell in the "Process Year-Book" as reliable data, I may mention only two curious points.

In the first place, the stop to be used grows rapidly smaller as the screen ruling becomes coarser, when the need for extreme definition becomes less. The second point is the increase in exposure necessitated by small stops. To put it in a more practical way, one would require to be convinced of an enormous improvement in results to be reconciled to giving a "rush" coarse screen (50 line) negative *nine times* the exposure which the same original would require with 150 line screen; or after having done the above newspaper job with a stop equal to *f*/100, to be expected to do an extremely fine job, requiring a 200 line screen, with a stop equal to *f*/25!

With regard to the system of Messrs. Smith and Turner, I think Mr. Bierman is in error in attributing change of stop size with change of screen to them. The fault I have with their system is due partly to the factor which Mr. Bierman has been working on, namely, diffraction. I have been working at the same subject, but not in measurement, which I am inclined to regard as of little use in practice, as the average operator and the average camera are not equal to working to sufficiently exact limits.

Diffraction plays a very important part, but so do several other less calculable factors, such as effect of the glass and balsam, minute differences in width of line, and so on, so that careful working

reveals differences in the working screen-distance of paired screens oven by the best makers.

The system which seems most practical, although to the mathematical mind it may be unsatisfactory, is to keep the stop a constant fraction of the extension, and to find out, once for all, for each individual screen, the distance at which it gives the best result, after which it is a simple mechanical problem to ensure that this distance is employed whenever this screen is used.

There are many other interesting points suggested by Mr. Bierman's article, and by consideration of the figures which Mr. Grenell has published, particularly from the point of view of diffraction, but this letter is already sufficiently lengthy.—Yours faithfully,

Edinburgh. W. B. HISLOP.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. O'BRIEN.—The only lamps for high-power light, apart from gas or electric current, are the incandescent paraffin mantle lamps of either the Kitson Empire Co., Stamford, Lincs., or Blanchard Lamps, Ltd., 151, Farringdon Road, London, E.C.1.

R. B.—A good cement for fastening metal to cloth or other fabric may be made by dissolving gelatine in acetic acid till it is about as thick as cream. This, unlike other glues, does not shell off the metal when hard. The solution is made without heat and remains liquid at ordinary temperatures.

L. J. BOON.—The yellowish marking on the print is evidently due to faulty fixation, that is to say, the whole of the print has not been fixed, probably owing to omission to keep the prints moving and separated from each other while in the fixing bath. A fixing bath which has been used for too many prints favours the defect.

J. S.—In most cases the bloom will easily come off on rubbing with ordinary indiarubber. A soft rubber suffices with some prints, and is really the only one it is safe to use, although with care a harder rubber may be used for obstinate cases. Another means is to use the very fine abrasive preparation made by the Vanguard Manufacturing Co., Maidenhead, as "Frictol." We have used this with good results.

H. T.—So far as we know there has not been a copyright case in the Courts at all corresponding with the circumstances you mention. The case is a rather doubtful one, but our opinion is that in the absence of any definite provision the copyright in the negatives would remain the property of the firm after the operator had left, in which case, of course, the employee could not restrain the firm from issuing prints from the negatives

K. P.—So far as copyright law is concerned, you are at liberty to take and supply a second set, even though the views turn out practically the same as the first lot, but under common law it is quite possible that your contract with either one or other of the two customers would be held to be broken on account of the similarity between the pictures. Both legally and morally you will be well advised to make the views substantially different.

P.—We are not surprised that half-watt lamps were found ineffective, as these are perhaps the least suitable for iron papers. We do not profess to know what arcs are like in the old pattern Halden machine, but we think it very likely they are of a very antiquated type. We think it would be worth while to have them replaced by modern enclosed arcs, the best of which for this work are those of the Westminster Engineering Co., Victoria Rd., Willesden Junction, London, N.W.10. We are sure this Company would give you quite candid and reliable advice in the matter.

M. P.—It is difficult to assign an exact position for the diaphragm, but judging from the Aldis cemented lens or the Cooke lens, which closely resembles yours, it should come behind the centre negative lens at the point we have marked on your diagram (returned). Your best plan would be to cut a card diaphragm, say, *f*/11, and move it to and fro in the tube till you find the best position. The difficulty of inserting a Waterhouse diaphragm can be surmounted by making a tube adapter or sleeve (as we show on diagram) to bring the whole of the lens outside the camera. The slot could be cut through this as well as through the original tube.

B. F.—(1) Bolting silk is quite satisfactory for certain diffusion effects, but it must be used within an inch or two of the paper, not anywhere between the lens and the paper. If you use fine chiffon, on the other hand, you can fix it on the lens hood. (2) You are working on a very wrong plan as regards the fixing bath, and we are not surprised that you get blisters. Make up the bath with alum, sulphite, hypo and acetic acid, according to the fixing-hardening formula of almost any maker of bromide or gaslight paper. (3) Blue spots are generally caused by particles of iron in the wash water, or sometimes from bad samples of alum. We advise you to tie a flannel filter over the tap, and if there is any reason to suspect the alum get a reliable supply from a chemical firm of repute.

C. G.—Impossible to answer all your questions because you do not even say what are the sizes of the tanks, or what the material (plate or film) which you are developing. However, our opinion is that you must, of course, have a water tap over the washing tank, and it would be a great convenience to have another water tap for rinsing negatives as they come from the fixing. Certainly you should have a sink in which the fixing tank and the washing tank stand. The developing tanks should be on a bench adjoining, at least 6 to 7 ft. from the fixing tank. Height of bench and height of sink should be such that the tops of the tanks come at about waist level. Have a red lamp with switch for the development work, and a white light (behind a sheet of opal glass) immediately over the sink for convenience in examining negatives without the danger of letting hypo splash on the floor or elsewhere.

J. S.—The particulars given in your question are contradictory. If the customer ordered and paid for the portraits, the copyright became automatically his, and is almost certainly still his at the present moment. The only way in which it could have lapsed altogether is through the photographer having died at such a time that the term of copyright had come to an end before the present Act came into force. As the present Act came into force in June, 1912, it is hardly likely that the copyright has expired. This being so, we are unable to understand what you mean by saying that the customer was refused the right to have them reproduced elsewhere. If the copyright was his, he had a perfect right to have them reproduced by whom he liked. The explanation may be that the sitting was what is known as a "free sitting," that is in response to an invitation on the part of a photographer, and that the "order" was for prints supplied subsequent to the sitting.

Contents.

SUMMARY.

The Photographic Fair, which opens on Monday next, May 1, at the Horticultural Hall, Westminster, includes a very full showing by the manufacturing and dealing firms in the photographic trade. We publish a long advance notice indicating particularly new introductions which will be found at the various stands. These include new brands of roll film, self-toning and development papers, cameras and other apparatus (at reduced prices), and many other new introductions of interest to the professional and amateur photographer. (P. 243.)

By courtesy of Mr. Arthur C. Brookes we are able to publish an advance review by Mr. F. C. Tilney of the collection of examples of portraiture by American professional photographers which will be on view at the Photographic Fair during next week. Mr. William Crooke is to judge these exhibits for the award of a thirty-guinea cup. (P. 243.)

The Congress of the Photographic Dealers' Association will be held during the Fair week. Particulars on page 253.

This week we begin the publication of a series of articles by a portrait photographer of eminence on the business side of his profession. Later chapters will deal with systems of book keeping and costing, collection of accounts, etc. (P. 250.)

In a leading article we have some hints to give on the selection of lenses for commercial photography and utter a caution against the choice of large aperture instruments of long focus. For many purposes the inexpensive long focus single lenses may be employed with advantage, whilst the telephoto lens has a distinctive usefulness. (P. 242.)

Photographers in the smaller towns could advantageously make much greater use than many of them appear to do of the various attractive styles in enlarged coloured portraits which are offered to them by the various trade firms. (P. 242.)

Some of the amenities which should be observed in photographers' written communications with their customers are mentioned in a paragraph on page 242.

A contributor gives an account of his strenuous experiences in using drain pipes for conversion into tanks for development of amateur films. (P. 253.)

Reduction in the prices of Platinotype and Palladiotype papers is announced by the Platinotype Company. (P. 258.)

The possibilities which are contained in the latest reports of the process of photo-telegraphy invented by M. Belin, of Paris, in the transmission of photographs, etc., for reproduction in the newspapers are the subject of a paragraph on page 241.

EX CATHEDRA.

The Prospects of Photography.

The strength of photography as an industry, which is to be shown next week by the important displays of goods at the Photographic Fair, is a theme which will bear a little stressing at the present juncture when complaints are not uncommonly heard of quiet conditions of business. Depressed as some branches of the photographic trade may be, it is impossible, on deliberate consideration, to take a pessimistic view of the future of any department. Portrait photography, for the time being, continues to suffer from the prevalence of unemployment and the oppressive burdens of taxation. As both of these factors tend to be relieved—and it may be expected that the next few months will show a substantial improvement in the national affairs—we are convinced that both the cheapest and most expensive grades of photographic portraiture will enter upon a period of prosperity at any rate as good as any which they formerly enjoyed. In the cheaper grades the photographic portrait has become an article of commerce in thousands of homes in which previously it had been the rarest of luxuries, whilst the higher artistic standard of the best kinds of portraiture must result in a greater patronage of photographers by the moneyed and leisured classes. Similarly, the hand camera has become the pastime of large sections of the public to whom it was previously strange, an extension for which credit must be ascribed in part to the advertisement which photographic results obtained in many ways during the period of the war. Broadly, it may be concluded that all branches of photography will share in full measure in a revival of the general trade of the country.

* * *

Photo-Telegraphy

The "Times" in its issue of Saturday last, April 22, had a column article from its Paris correspondent giving a general description of the latest results obtained in the telegraphy of drawings and photographs by M. Edouard Belin, who has been engaged upon this subject for the past twenty-five years. As previous accounts which have appeared in our own columns have shown, M. Belin had come some years ago to a practical solution of this problem, and his latest achievements now appear to have brought the process to a stage at which it promises to exert a profound influence upon the methods of collecting illustrations for the daily Press. According to M. Belin it is now possible for a Press correspondent to go to any telephone call office and connect there his little apparatus for the transmission of a photograph. On being connected in the usual way to his office, a receiving instrument is affixed to the instrument in this latter, and within the space of five or six minutes a drawing, photograph, or piece of manuscript can be reproduced in the office of the paper. The "Times" reproduces the message in the holograph of M. Briand received in Washington last

October from Paris by wireless transmission in conjunction with the Belin system. One congratulates M. Belin upon these results, not only on the ground of scientific achievement, but for the reason that we may number him among the experimenters who have been "in photography" for many years. He has always been a keen student of photographic processes and is the author of an excellent French treatise, "Précis de Photographie Générale," published in 1905.

* * *

Speculative Portraits. When one has had, as we recently have, an opportunity of looking at the many varied and admirable styles of coloured photographic enlargements supplied by the trade firms for studios of all grades of status, we are more at a loss than ever to find an explanation for the unattractive appearance of the show windows or display cases of so many photographers, particularly those in the smaller provincial towns. In the large centres competition is a goad which has its result, but where it is less active there seems to be a disposition to think that a few photographs of the kind that happen to be coming from the workrooms are all that is required for a window display. Considering the relatively low prices at which attractive enlargements in colours may be obtained from the enlarging firms, it is somewhat surprising that a greater number of photographers do not "speculate" in them. Probably if they knew of the substantial orders given by their more enterprising brethren purely for portraits of this kind, which have not been ordered by the sitters, yet, nevertheless, are found to sell readily, they would feel a greater degree of confidence and would have the satisfaction not only of making their window displays a real attraction to the passers-by but at the same time of doing so at a substantial profit to themselves. In most places a few enlargements ordered in this way can hardly be called "speculative;" they would be better described as "gilt edged." It is hardly necessary to add that ordinary discrimination must be used in the choice of the style of enlarged coloured portraits which are ordered for "speculative" sale. The range of styles, however, offered by the enlarging firms permits of very nice adjustment to the judged standard of local taste in such matters.

* * *

The Art of Letter Writing. Photographers of all people should be expected to exhibit a certain taste and aptitude in their written communications with their customers. Most of them, we imagine, have the desire of being regarded by their customers as, at any rate, considerably above the intellectual level of the ordinary shopkeeper. Nevertheless, the standard of correspondence, and even of printed letter headings, is lamentably low. The stationery problem is easily solved by giving a free hand to a printer of taste and discrimination in such work. As regards the mechanical production of the letters themselves, the use of a typewriter is to be commended to those undertaking their own correspondence unless the handwriting has both legibility and a certain style. As regards the wording itself, perhaps the most useful thing which can be said within the compass of a short note such as this is to avoid the redundancies and jargon of commercial correspondence. Let the matter be stated as briefly and clearly as is consistent with courtesy, holding aloof from such unnecessary turns of speech as "we may say," and commercial contractions, such as "same," "even date." A customer will judge a man by the style in which a letter is written as much as by anything else; and there is no conceivable reason why the most rigorous business policy should not be pleasantly clad in good English. An unforgivable sin, which we sometimes find committed, even by firms of standing, is to answer a letter by writing a few lines on the customer's communication and returning it to him.

LENSES FOR COMMERCIAL PHOTOGRAPHY.

THE photographer who caters for manufacturers, architects, house agents, *et hoc genus omne*, requires a much more extensive assortment of lenses than is needed in any other branch of the profession, and it is desirable therefore that such money as can be appropriated to this purpose should be expended, so as to secure the most serviceable set of tools. The exact composition of the outfit will, naturally, depend upon the means of the purchaser, but there are certain rules, or perhaps what might better be called facts, which hold good in every class.

The first and most important from the point of view of cost is that for lenses of considerable focal length, there is no necessity for large apertures. With any focal length over ten inches it is rarely possible to work with a larger aperture than *f*/8, *f*/11 or *f*/16 being usually the largest that will give satisfactory depth; the extra cost of an instrument working at, say, *f*/6 is therefore absolute waste, as many have found to their sorrow. Another fact is that with such long focus lenses it is not essential that they be rectilinear, for when only a narrow angle is being subtended there is no perceptible curvature of straight lines in the image made by a single lens. These two points indicate that what are commonly known as "convertible" lenses are particularly suitable for commercial work, the complete lenses having maximum apertures from *f*/5.6 to *f*/8, according to size and series, while the singles give sharp definition at their full apertures of *f*/11 to *f*/12.5. The maximum apertures are only obtainable when the single components are of equal focal length, but as the difference is not great it is wiser to select a lens in which the components are different, that is to say, in the case of an 8½-inch combination the singles should be 17 and 12½ inches respectively, instead of two of 14½ inches. An additional advantage of this type is that other single elements may be added as desired, one of 17 inches giving a combined focal length of 10 inches, or a 21-inch giving an 11-inch combination. The single combinations of many other anastigmats may be used alone, but as a rule require stopping down to an actual aperture of *f*/16 before critical definition is obtained. Cooke and Aldis lenses cannot be used in this way, but both these makes are arranged to take interchangeable front lenses which will increase the focal length by 50 or 100 per cent.

The actual size of the lenses must, of course, be determined by the size of plate most commonly used, the great essential in nearly all commercial work being good perspective, which means a comparatively distant standpoint. Therefore a lens which gives a satisfactory rendering of a piece of china upon a half plate will not do so upon a 12 by 10, as in the latter case the distance would have to be reduced by one half, and the perspective will be too violent. It is difficult to lay down any definite rule, but it is safe to assume that for photographing small articles the lens should have a focal length at least equal to twice the longest side of the plate to be used.

The telephoto lens has not yet received the attention of commercial photographers to the extent that its merits warrant, and we commend its use to those who do not shrink from the little trouble involved in mastering its working. For a comparatively small sum any good quality anastigmat or rectilinear lens can be fitted with

an attachment which will increase its focal length by three, four or more times, so that an image of any required dimensions can be produced from the most favourable standpoint.

Those who cannot afford an assortment of modern lenses will find that for this class of work the older types of rectilinear and symmetrical lenses are little inferior. If of good quality these will cover their normal plate perfectly at *f*/16, while for subjects occupying only the centre of the field larger apertures may be used, but as commercial work usually calls for considerable depth of definition the smaller aperture is usually necessary. The portrait photographer who is in possession of long focus portrait lenses will find these very serviceable for "still life." The larger sizes of the ordinary single lenses, as issued by Dallmeyer and Taylor & Hobson, may also be pressed into service with good effect, and are much to be preferred to even the best anastigmats of short focal length.

A very useful adjunct to the lens outfit is a prism or mirror which can be affixed to the lens for the purpose of photographing objects situated either below the camera or high above it. When working away from the studio it is difficult to improvise a vertical studio stand, especially with a large camera, but with the prism or mirror it is easy to photograph ceilings and monumental brasses, or to make "shadowless" photographs of small objects. Such negatives are, of course, reversed and are best taken upon films or printed upon transferrotype paper which corrects the reversal.

AMERICAN PORTRAITS AT THE PHOTOGRAPHIC FAIR.

By the enterprise of Mr. Arthur C. Brookes, British professional photographers have the privilege of comparing their work with that produced across the Atlantic. The Exhibition of American Pictorial Portraiture, which will be opened next week as one of the attractions of the Photographic Fair, should be intensely interesting, because it may be taken as a true and fair sample of rank and file work.

But although the names that we know are not on the prints, the average of the work is a high one. That it is all pictorial portraiture, as it purports to be, is by no means the case; the majority of the prints are ordinary portraits on behalf of which the only claim to a pictorial treatment rests upon spot-lighting, back-lighting, granular textures and so forth.

The most pictorial example of all occurs in the consignment from the Crowley Stokes Studio, Cleveland, Ohio. This is a landscape—a fine park-like scene, though rather fuzzy, and containing in the foreground small figures of a lady and a baby, the latter on its back on the grass. But it requires some stretch of the imagination to regard these little figures as portraits. Anybody who knew the baby well might risk a recognition, but the presumable mother would defy identification. Garden and park portraiture has been referred to in this journal as a possible field for a new development often enough, and this is the first attempt we have seen in that direction. It suffers from being too parky.

There are also some examples of semi-nude, half-length nude and other interesting things, which can only be described as figure-studies. In this country, at least, ladies do not sit for "portraits" in the nude, or in acrobatic postures with a winding sheet, such as Nickolas Muray, of New York, sends. His distinguished work has already graced the walls of the London Salon, together with that of Rabinovitch, New York, whose portrait of Tagore will be remembered, and that of a young girl, whose characterful face peers out of a black environment in which the dress and the background are indistinguishable.

Other likenesses of well known celebrities are to be seen in the show, the best being, perhaps, the very artistic portrait by R. J. Dooner, Philadelphia, of Pennell, the famous pen-draughtsman. In this there is the complex lighting which American photography has made its own specialty, but which in this case is used, not abused, and is explained by a clever treatment of the background that suggests a source of light for the bright accents. This print is remarkable for airiness and space, while giving full value to the character of the sitter. Mr. Dooner also sends a portrait of the American painter, W. McClure Hamilton, standing at his easel, but the spatial qualities of the Pennell portrait are here quite lacking. A large head, of fine style, in a Bartolozzi red on a grained paper like a Michalet, will be, or should be, much admired. A portrait of Tolstoi and other celebrities are amongst an excellent set sent by Miss Clara E. Sipprell, New York. They are all straightforward, artistic work.

Another excellent group is by Miss May L. Smith, of Binghampton, N.Y., composed of portraits of ladies and children. One particularly delightful baby wears an expression of preoccupation or abstractedness which is very winning, and the interlocking of its pudgy little fingers is most fortunately given.

It is evident that the American parent is enthusiastic in the practice of child-portraiture, to judge by this selection which reaches us from all parts of the great continent; and as a rule the successes are to be found in this genus. Miss Sophie L. Lauffer, of Brooklyn, shows one or two very vigorous presentments of aged persons not remarkable for beauty, but she redeems the attractiveness of her exhibit by a large head of a child in a light key. Two children, in mob caps, are likewise the best things in Miss Peggy Stewart's selection from Canandagua, N.Y. They are brightly yet firmly handled, and have abundant infantile charm. Her other works are less simple in motive: a man, for example, whose face is given with a tightness of focus that is unusual, whilst his shoulder is positively dematerialised by diffusion. Another man is photographed with beads of perspiration on his brow.

Other attractive children will be found in the collections by E. Willard Spurr, Waterloo, especially the girl in a kind of basket hat, with her pretty pose; and by Mrs. Emma Hilton, New York, particularly the delightful group of a boy and girl playing with a telephone receiver. In some of this lady's work there is a curious impinging of dark tones upon the light parts of the print. Whether this is by accident or intention it is difficult to say, but it imparts a sort of transparent, alabaster look to her forms that can hardly be thought desirable.

Of more purely pictorial work there are some good examples by J. E. Mock of Rochester. They are versions of a model who holds a dish of fruit À la Titian's Daughter. In most cases the poses are too violent and strenuous; but one is really fine in style and in its quiet grace does remind one of the famous Titian. The Gerhard Sisters, of St. Louis, have also the grand style in mind. Their designs are good, and one, a girl leaning over in contemplation of a vase, has beautiful lines. All these are executed in a granular method, which is often aggressive unless one puts the print far enough off from the eye. W. A. Vinock of New York also affects a strong grain. This and many another innovation, is probably an excusable attempt to get something that has not been done

before. All such motives may have a commercial justification, but it is difficult to see how such onterprise will exalt the standard of portraiture by photography, whether we claim, or not, that it is pictorial.

For the popular taste perhaps the bright, sparkling and rich style adopted by F. A. Free, of Davenport, is most likely to meet with all-round commercial success. He gets remarkable animation and nttractiveness of personality.

If an exhibition is able to inspire in any way our own workers it must be in the direction of artistic insight and feeling, and for any such suggestions in the Horticultural Hall the thanks of the profession will be due to Mr. Arthur Brookes for having invited the American professionals to submit their work to our judgment, and to Mr. Mackie who, we understand, is the "producer" of the show, as the stage term goes.

F. C. TILNEY.

THE PHOTOGRAPHIC FAIR.

THE Fair, which opens at the Horticultural Hall, Vincent Square, Westminster, on Monday next, will be found to represent as great a gathering of photographic manufacturers and dealers as at any of the previous Fairs. Moreover, there is this year a feeling of strength, arising on the one hand from a more settled state of the national affairs and on the other from the announcements of reductions in the prices of apparatus which figure prominently in the propaganda of camera makers. Last year, it will be remembered, that the Fair opened on the "Black Friday," from the labour point of view, under the threat of a general railway strike throughout the country in support of the Miners' Federation. Fortunately on that occasion wiser counsels prevailed, and the Fair, during the following week, enjoyed what we believe as a record attendance by the public. While that interest was satisfactory, so far as it went, the fact could not be disguised that the high level of prices was a hindrance to the expansion of photography in correspondence with makers' resources in this country. This year as great an interest on the part of the public may be counted upon, in fact greater, since those interested in the pastime of photography can get their equipment at substantially lower prices, and may reasonably look forward to further reductions not only in the initial cost of apparatus, but in the running expenses represented by sensitive materials, chemicals, and the minor accessories. Thus, as we point out in a paragraph on an earlier page, there is the justification for taking a more cheerful view of the near future of photographic business than we find commonly expressed in various quarters. There seems little doubt that the present season will be a thoroughly good one in the sales of apparatus and materials for amateur work; and revival in portrait and commercial photography will follow close upon the heels of a similar improvement in the general trade of the country; and of the latter, returns of various kinds which have appeared in the daily Press provide considerable evidence.

Inasmuch as our issue of next week could not be published until the day before the closing of the Fair, we have followed our usual custom of obtaining from the exhibitors advance particulars of the goods, and particularly the new introductions, which they will show. As will be seen from the notes which follow in an order corresponding with the numbers of the stands, there is a goodly array of these new introductions, the most notable of which may be signalised as follows:—

- A new brand of roll film.
- Two collodion self-toning papers.
- Warm tone development papers.
- Grades of Platinotype.
- Numerous new models of folding film and plate cameras.
- A new folding reflex.
- *f*/2.9 lenses.
- Cine taking and projection lenses.
- Electric drive and distance control of cinematograph camera.
- New type of exposure meter.
- Dark-room lamps.
- Developing tanks for plate and film.
- Printing and drying machines.
- Apron printing machines.
- Vertical self-focussing enlargers.
- Dry-mounting iron.
- Passe-partout requisites.
- Studio spotlight.
- New styles in enlargements in water colours.
- Art leather articles.
- Handbooks on photography.

Although the Professional Photographers' Association haa this year chosen a later date and a different meeting place for the holding of its annual Congress, there is no doubt that the Fair will be largely attended by professional and commercial photographers in the Metropolitan area and from the Provinces. That such will be the case is fairly indicated by the fact that firms whose interests are exclusively with the portrait and commercial photographers are exhibiting as usual, while the general manufacturers and suppliers are giving their normal degree of prominence to professional apparatus and materials in their displays. As already announced professional photographers may obtain a ticket for admission to the Fair during the whole course of the week on application to the Organising Secretary, Sicilian House, Southampton Row, London, W.C.1, at the cost of 1s.

A special attraction is provided for the professional portraitist in the shape of a large collection of examples of portraiture by leading studios in the United States. A review of these portraits by Mr. F. C. Tilney will be found on another page.

The Congress of the Photographic Dealers' Association will be held during the Fair week in accordance with a programme, particulars of which will be found elsewhere in this issue.

Stands Nos. 1 and 2—Kodak, Ltd.

IN the professional section of the Kodak Co.'s exhibit will be shown, among many other items, prints on the Kodura, Kodura Etching Brown and Kodak bromide papers. The Eastman projection printer, with its miraculously ingenious feature of self-focussing, will attract attention, and so also will the diffusing discs which are now obtainable for attachment to any photographic lens, converting the latter into a soft-focus objective. The moderate degree of softening in the definition which is produced by this attachment should find wide favour. A new accessory is the Kodak focussing spotlight, a little electric lamp for the studio fitted with a lens and diffusing screens and serving as an auxiliary source of light capable of infinite adjustment, for the purpose of introducing light accents into a portrait, relieving flatness of lighting, and, if the photographer has a liking for theatrical effects in portraiture, providing the means of getting the showy and striking effects which are fashionable in some quarters.

The dealers' section of the Kodak show will be fitted up as a shop front, the windows of which will be changed every day. One window will show how to make an effective display in a large space, while in the other smaller window the visitor will be able to learn how to produce an equally effective style of window dressing, even though he has little space at his disposal. There will also be a display of Graflex cameras, fitted with telephoto lenses, as well as many new aids to picture making for the amateur. Those engaged in developing and printing of amateurs' films should not omit to note an electric heater for the tank solutions, by means of

which the latter are very conveniently and quickly brought to a proper working temperature simply by immersion of the heater in them for a minute or two.

The Wratten Division of the Kodak Co. will include Wratten light-filters, with transparencies showing the actual light transmitted by them; also reproduction of engravings and coloured originals in monochrome and colours on film. In addition to Wratten dark-room lamps and safelights, aerial mapping cameras will be shown, and examples of commercial photography on film.

Stand No. 3—White Band Manufacturing Co., Ltd.

New introductions at this stand are a one-solution concentrated developer for all makes of British gaslight and bromide papers and plates; ready-for-use gaslight and tank developers, green, blue and sepia toners; a glazing solution (Glosso) for prints and an intensifier of the re-developer kind. The firm is also showing the Loopa daylight developing tank for beginners' use and of extremely simple construction. The Monomet developer and the various compressed tablet and packet developers, in addition to the mountants, fixing salts, and other chemical preparations, will form part of the exhibit.

Stand No. 4—Johnson, Matthey and Co.

Inasmuch as the salts of silver, gold and platinum, so essential to photographic processes, reach us now-a-days in the manufactures of the sensitive material firms, an exhibit such as that of Messrs. Johnson, Matthey is of special interest in showing the refined skill which is applied to the manufacture of these so-called "raw materials" of the photographic industry. One cannot look at the glittering specimens of silver nitrate, gold chloride, and potassium chloroplatinite without being convinced that at this initial stage nothing has been left undone in giving to these products the highest degree of purity. Messrs. Johnson, Matthey's name stands for this hall-mark of quality, and their exhibit serves as a useful reminder of the debt which users of photographic materials owe to the skill and science of the refiners of precious metals.

Stand No. 5—Sanger-Shepherd and Co.

The student of sensitometric methods in the testing of plates and printing papers has special reason to spend a time at Messrs. Sanger-Shepherd's stand, where are shown instruments—some of them quite simple and inexpensive—for the measurement of density, exposure of plates, etc. These include the even and step wedges by the use of which many sensitometric experiments are greatly simplified.

In orthochromatic photography the exhibit includes numerous accessories, such as the firm's well-known graduated light-filters and filters, cameras, and other appliances for processes of colour photography.

Stand No. 6—R. and J. Beck, Ltd.

Messrs. Beck's exhibit will consist of a complete series of the photographic lenses manufactured by them in various forms of mountings and shutters together with examples of work done by the lenses. The latter include the Isostigmar, Neostigmar, and Bystigmar series.

Stand No. 7—The Platinotype Co.

Some recently introduced new grades of Platinotype, Palladiotype and Satista papers will be shown for the first time, and demonstrations given at frequent intervals of the great simplicity of the manipulation of these papers. The Platinotype Company are fortunate in being able to put before the eyes of the visitor, within a few seconds, the making of a print in one or other of these media, and the specimens which they are accustomed to show must always awake envious thoughts in the minds of those who set store by superlatively beautiful technical quality in prints.

Stand No. 8—The Autotype Co.

The growing favour of the Carbro process among both professional and amateur photographers is reflected in the announcement that the Autotype Company will devote a chief part of the services of their staff at the Fair to demonstrations of this method of making carbon prints. They will also exhibit their latest styles in carbon and bromide enlargements, finished in monochrome, water colours, etc., also ivory and ivorine miniatures and vitrified copper enamels. As on previous occasions a special feature will be prints from portrait negatives illustrating the great range of colours (of the image and its support) offered by the double transfer carbon process.

Stands Nos. 9, 22, 23, 24—Amalgamated Photographic Manufacturers, Ltd.

Corresponding with the formation last year of this combination of the interests of Messrs. Marion, Paget, Rajar, and other firms, the manufactures of the Company are grouped under the single title, although the goods will be found displayed at different stands.

Perhaps the most notable of the exhibits will be the new models of roll-film and reflex camera manufactured by the Kershaw branch of the Company, and just issued under the trade mark of "Apem." The film cameras are of both box and folding pattern, and the reflex, in quarter-plate size, represents the success with which the manufacturers of the long-renowned Soho reflex have applied their resources to the supply of a reflex instrument at a most popular price. Another new introduction, marking the larger entry of Messrs. Kershaw into the manufacture of photographic requisites, is the developing tank which we reviewed a few weeks ago. At the Fair a daylight developing tank for roll-film will also be shown, and also a circular print trimmer.

Professional photographers will have the opportunity of seeing the unique Norka studio camera and the electric studio lighting outfits in which the Marion branch of the A.P.M. has so long specialised.

In photographic materials the exhibits will show the results obtainable on Rajar, Marion and Paget plates and papers, and of course also the latest specimens of the Paget process of colour photography.

Stand No. 10—Adams and Co.

A Fair would be incomplete without some new design of hand camera from makers of such experience and originality as Messrs. Adams. This year it takes the form of a new folding reflex—the Aidex made in quarter-plate size only, instantly opened and erected for use, yet exceedingly small and compact when folded. These facilities at the same time permit of any lens from 6 to 9 inches focal length being fitted, as also various focal lengths of telephoto. The Aidex is supplied with the well-known Minex self-capping focal-plane shutter.

The folding Minex itself will be shown in the 1922 model embodying a number of improvements, whilst retaining the triple extension, revolving back, large rising front and other features of this notable instrument. In the box form Minex A a long viewing hood is provided together with rotating back and automatic adjustment of mirror and shutter. These Minex instruments will also be shown in tropical patterns of brass-bound teak.

Other items in Messrs. Adams' exhibit will be the studio Minex camera and the series of folding Vesta cameras, an addition to which this year is a shutter giving speeds up to 1-300th of a second.

Stand No. 11—Taylor, Taylor and Hobson, Ltd.

Among the new optical introductions of the year are a series of ultra-rapid *f* 3.1 cinematograph-taking lenses designed by Messrs. Taylor, Taylor & Hobson, which will be shown at this stand. The firm has also introduced a new cinema projection lens, giving a greatly increased luminosity on the screen. The well known series of Cooke lenses, of apertures ranging from *f*/3.5 to *f* 6.5, will, of course, form a prominent part of the exhibit, and there is also the recently introduced Cooke fixed-focus telephoto lens. Photographs and enlargements serve to demonstrate the high optical excellence of these instruments.

Stand No. 12—Leto Photo Materials Co., Ltd.

The excellent results which are obtained by modifications in the treatment of the renowned Seltona (collodion) paper and Boardoids are to be shown in profusion at this stand, where the visitor may see the definite and agreeable tones obtained according as the paper is fixed with or without the use of a salt bath, and also the striking effects most readily obtained by partial use of a salt bath and of platinum toning. The Leto Company have a number of specialties in the way of plate markers, frame border negatives, shaders, etc., which will be shown.

Stand No. 13—O. Sichel and Samuelson.

This stand will be devoted specially to the exhibition and demonstration of machinery for the development and printing of amateurs' film negatives. Messrs. Sichel will show the Hodgson printing machine and the Hodgson drier, both of which have been reviewed in our pages, and also a cheaper printing machine and a series of new iron tanks measuring 42 by 12 by 8 inches for the handling of film negatives. It is hoped also to show a new pattern of vertical enlarger shortly to be placed upon the market at a moderate price. Messrs. Sichel are also specialists in the supply of oval and square frames, and these goods will form a part of their exhibit.

Stand No. 14—Ross, Ltd.

The professional and the amateur will have every opportunity of choosing a lens for their requirements from the many series of high-class instruments of which Messrs. Ross are the designers and manufacturers. These include the *f*/4.5 Xpres lenses, for studio and outdoor work and for hand cameras, and the Ross cabinet and other lenses of the portrait type. Among lenses of somewhat lesser aperture are the Homocentric and the Combinable, the latter affording three focal lengths by the purchase of a single instrument. Then for Press and other cameras the extension of which is limited there are the *f*/5.4 and *f*/6.8 Telecentric lenses affording a focal length very nearly double that of the permissible camera extension and peculiarly suitable for the photography of such different subjects as sports and Nature studies. Messrs. Ross will also show their established patterns of hand and stand cameras and their most recent work, the cinematograph projector outfit, as used in many super-cinemas.

Stand No. 15—Kosmos Photographics, Ltd.

A new Kosmos paper, self-toning collodion, will be introduced for the first time at the Fair, and examples of its use shown. The exhibit will likewise draw special attention to the results on the Company's newly-introduced Novex plates, as shown by prints and enlargements on Vitegas and Kosmos bromide and on Novex gaslight papers. Workers of the Bromoil process will be provided with a demonstration of the special suitability of Vitegas paper in the shape of Bromoils made from prints obtained on it. The contents of the Kosmos stand will also include a collection of portraiture by British and Continental artists.

Stands Nos. 16 and 17—Houghtons, Ltd.

Some three hundred different models of British-made Ensign cameras will be shown by this leading firm of manufacturers. Among them are a considerable number of new models, notable among which are the Ensign Klitos, single extension hand cameras for plates or film-packs in the 3½ by 2½ inch size and also the 8 by 12 cm. size, the latter, the No. 4 standard size, yielding pictures measuring 4¼ by 2⅞ inches. The prices of these cameras range from £3 17s. 6d. A de luxe model will also be introduced fitted with a high-class *f*/4.5 anastigmat and Ilex Acme shutter. Among reflexes Messrs. Houghtons will show at the Fair the Tropical-Popular model of their Ensign reflex. Other new models of folding hand camera are the flush back popular Ensigns and others of similar design fitted with *f*/4.5 lenses; and a popular model of the Ensignette. Some new patterns of folding metal tripods, dark room lamps and printing boxes, printing frames and albums will likewise be included in this comprehensive exhibit. In particular reference may be made to Mr. K. C. D. Hickman's water circulator, an appliance for the conversion of any dish or vessel into a washer for negatives or prints.

Equipment for developing and printing of amateurs' films will be shown in the shape of printers, driers and tanks for this branch of work, together with advertisement showcards, etc., for the use of dealers.

In a room on the first floor next to the exhibition of American portaiture Messrs. Houghtons are bringing together an exhibition of their apparatus and other requisites for professional portrait photography, including studio cameras and stands, studio accessories, equipment for the dark room and printing room, mounts and albums, among all of which there will be an exhibit of English professional portraiture.

Stand No. 18—Thornton-Pickard Co., Ltd.

The widely-known specialities of this firm, many of which have been issued in improved models for the coming season, include such old standbys as the T.P. roller-blind shutter, the College, Imperial and Royal Ruby field outfits, and a great variety of hand cameras. Among these is an improved Imperial pocket camera, the Klippa collapsible camera, an all-weather press camera, and various models of the Thornton-Pickard reflex. Enlargers and other accessories will be included.

Stand No. 19—Newman and Guardia, Ltd.

At Messrs. Newman & Guardia's stand we are promised a new model of the Sybil folding pocket camera, an addition to the many models of this most excellent instrument for roll film or plates. A new folding enlarger, for use either with daylight or by artificial light, will be shown. The exhibit will, of course, include the folding reflex camera which was the notable introduction at last year's Fair, and also ultra-portable tripods and other accessories for hand camera photography.

Stand No. 20—W. Butcher and Sons, Ltd.

Messrs. Butcher have many hand cameras to show, and commendably are emphasising the reductions in price which apply to them. For example, a new model of the watch-pocket Carbine is obtainable at £2 10s., and the Popular Carbine, for roll-film or plates, from £3 12s. 6d. in 3½ by 2½ and 2⅞ by 4⅞ sizes. Another plate camera, to which they are directing special attention, is the popular Cameo of 8 by 12 cm. size, priced at £3 7s. 6d. upwards. At the new prices a metal dark slide is included with each camera taking plates or films.

Their watch-pocket Carbine may be obtained in a roll-film model for 3¼ by 2¼ pictures, fitted with *f*/4.5 lens.

Amateur enlargers will be interested in the Primus half-watt light, suitable for different voltages. The light is given by a globe filament provided with a special mirror.

Messrs. Butcher are also showing a series of new models of electric dark room lamp, one of which is supplied complete with battery for use in houses where there is no electric current.

Dealers should not omit to inspect the sundries cabinet, for the display and handling of stock, which is made in polished oak with a glass top, and is sent out on loan free of charge.

Stand No. 21—Acme Art Association.

This old-established firm of colourists and artistic craftsmanship for professional photographers will show a selection of its recent work in miniature painting on ivory and ivorine, with and without basis, water colours, oils, pastels and pencil sketches. Recently it has taken up certain specialties in more popular demand such as statuettes and jig-saw puzzles, examples of which will be shown. And its very latest excursion into a new field of artistic work is in the fabrication of

leather hand bags, book covers, and even such articles as bedroom slippers. We have recently seen some of the first examples of these goods which are certainly of most artistic design and workmanship, and may very properly be offered for sale in many photographic businesses. We expect that the many women photographers will at once fall in love with them and will have no hesitation in adding them as a profitable side line to their portrait businesses. If any excuse were necessary—we do not think it is—it may be found in the fact that the goods differ distinctly from those which are on sale at the large stores or in the shops which handle articles of this kind: at the same time, they are made in a variety of styles. Moreover, the hand bags and book covers lend themselves to the inclusion of a miniature photograph and thus form most acceptable photographic gifts, as may be seen from the specimens at the Fair.

Stand No. 25—Criterion, Ltd.

At an attractive stand, representing an ancient half-timbered building, the Criterion Co. are bringing together a full display of results on the many descriptions of sensitive materials made by them. Prints on the Criterion Non-stress series of bromide and gaslight papers figure prominently in this display, as also do those on the firm's P.O.P. and Estona (self-toning) papers. Criterion plates and Criterion roll-film come in for equal emphasis. The film is now manufactured in 22 sizes, designated by letters from A to V, so that a given size is readily supplied for fitting to any camera.

As manufacturers of the Kerotype transfer bromide and gaslight papers, the Company is showing the many and varied artistic effects which are obtainable by the transfer of the prints to surfaces such as silk, satin, canvas, linen, wood, ivory, metal, etc. Professional photographers in particular will be interested in these prints representing effects which are very readily obtained with the new commercial material. For the professional who undertakes cinematograph work there is the Criterion cinematograph film both negative and positive.

Stand No. 26—James A. Sinclair & Co., Ltd.

The Fair is fortunate in including for exhibition a most important advance in cinematography in the shape of the electric drive of a cinematograph camera, which has been worked out by Messrs. Sinclair and applied to their surpassingly designed and made N.S. cine camera. The drive is provided by a small dynamo, taking its current from an equally small battery, the two together occupying only a few cubic inches of space, and weighing only 3½ lbs. The dynamo is mounted on a panel, which is instantly attached to the metal casing of the camera, the operation providing a gear wheel of the interior mechanism with a positive drive. The battery may be held on the top of the camera or carried by the operator. Although Messrs. Sinclair claim for their device that one battery will drive only 400 ft. of film through the camera, they are able to quote the experience of Captain Noel, in command of the photographic section of the Mount Everest expedition, that a battery suffices to drive nearly 2,000 ft. of film. It must be remembered, however, that the N.S. camera has an extraordinarily light-running mechanism, and it can hardly be assumed that the battery-actuated dynamo would drive even the claimed length of film in other cameras. The facility of a self-contained mechanical drive for the cinematograph camera is one of the greatest importance in topical work, since it makes the cine press-photographer as mobile as his colleague with an ordinary camera. How often is it noticed in topical films of current events that the cinematograph operator, owing to the fixed position of his camera on a tripod, has his view blocked at the critical moment. Messrs. Sinclair, moreover, have provided their electric drive with a further feature, which extends its scope, namely, that of starting and stopping the drive by electrical control at any distance. Their device for this purpose also includes a relay, which shows that the mechanism of the distant camera is working. This distance control is at present being used with very great advantage on the Mount Everest expedition for obtaining cinematograph records of Thibetan and other natives. On account of the objection, common to many of the races in the Far East, to allow themselves to be photographed, any camera which required the operator to be near at hand would be useless in many circumstances.

Messrs. Sinclair are, of course, showing their well-known photographic specialties, such as "Una" cameras, lens hoods, Bromoil requisites, etc. Among them is a neat frame finder and view meter which the user can set in exact correspondence with the focal length of his own lens and can fix conveniently on almost any type of folding or box camera. When not in use this little accessory folds flat within an incredibly small space.

Stand No. 27—Reginald E. Carter, Ltd.

Mounts and frames for the professional photographer form the staple of this exhibit. As agents for Messrs. Bartons', of Birmingham, Messrs. Carter offer an exceedingly fine display of mounts and mounting papers, folders and albums, and the very artistic and strong metal binding for framing in the passe-partout style. The opportunity for seeing the difficultly-describable tints and textures of mounts is one which forms a particular inducement for professional photographers to visit the Fair and to study at their leisure a collection such as that of Messrs. Carter's.

Frames in wood, metal, and leather, and also cases and rims for miniatures, are other specialties of this firm, which are offered in many exclusive and beautiful styles.

Stand No. 28—J. H. Dallmeyer, Ltd.

A new anastigmat, working at the great aperture of *f*/2.9 and issued in focal lengths from 1½ inches to 12 inches, is the outstanding novelty at this stand. Although the depth of focus of the medium and greater focal lengths is necessarily small, lenses of such enormous aperture open up possibilities for exposures under conditions which have hitherto been impossible. In the focal lengths from 8 inches to 12 inches the lenses are obtainable in a special type of mount allowing of diffusion in portraiture.

Fixed focus telephoto lenses (the Dallons) of aperture *f*/5.6 to *f*/7.7 are made in focal lengths from 5.3 to 17 inches corresponding with camera extensions from 3 to 8½ inches. These lenses are of extremely simple construction and can be fitted to many folding hand cameras, thus providing the facilities which otherwise would call for a camera of double extension.

Among lenses of the ordinary type, a new anastigmat is the Series V. Perfac, in which only four glasses are used and which is suitable for fitting to hand cameras. Messrs. Dallmeyer are showing others of their lenses including the universally known Patent Portrait Series and also a naturalist's reflex hand camera fitted with a Grandac telephoto lens giving 25 inches focal length at a camera extension of 6 inches and working at an aperture of *f*/10. A large, new catalogue announcing considerable reduction in price of a number of the lenses will be published on the opening day of the Fair and will be obtainable there.

Stand No. 29—John J. Griffin and Sons.

Messrs. Griffins, as suppliers and manufacturers of requisites for both the professional and amateur photographer, will exhibit on their stand a large variety of goods representing these two departments of their business. In the professional section they will show new flash lamps, the Howellite gas outfit for studio portraiture, and many pieces of apparatus and accessories for the studio, such as reflectors, vignetters, cameras and lenses, shutters and backgrounds. Among other items of workroom equipment they will exhibit card bevellers and cutters, printing-boxes, die-embossing presses, plate-marking platens, re-touching desks and their latest styles in mounts and folders.

For the amateur special prominence is given to results on

the Noctona (gaslight) and Goldona (self-toning) printing papers, on the firm's Bromoil papers and specimens of the use of the many Griffin chemical preparations in the shape of developers, fixing salts and toning compounds; also developing tanks for plates and roll film and a full range of folding plate and film and reflex cameras.

Stand No. 30—Elliott and Sons, Ltd.

Messrs. Elliott invariably provide an object lesson in artistic display of prints, and this year will apply their taste in this direction to the showing of leading professional, technical and portrait work on Barnet plates and papers. Their 550 H. & D. Super-Speed plate is obtainable also as a matt emulsion, facilitating hand work on the film with pencil, crayon, etc., to a remarkable degree. Examples will be shown. Their bromide papers include Verona for warm black prints by direct development, with others of cream and white colour in a wide range of distinctive textures, a feature of their business in which they have long successfully specialised. The Bar-Gas (gaslight) paper is made specially for the requirements of D. & P. trade, and their Bartona (self-toning) is a paper providing a wide range of tones simply by modification in the strength of the hypo-fixing bath.

Messrs. Elliott will also show Bromoil prints made on their bromide papers, and will have on sale a new and revised edition of the "Barnet Book of Photography," the regular publication of which has, unfortunately, been suspended for some years. Professional photographers are particularly invited to inspect portfolios of the firm's enlarging work finished in monochrome and colours.

Stand No. 31—Johnson and Sons.

As in previous years Messrs. Johnsons will show an exhibit composed of the bulk chemicals and chemical preparations (compressed tablets, packets and cartons) for the photographic processes. Naturally the amidol, metol, glycin and hydroquinone of their manufacture obtain a very prominent place in this display, as do also the single-solution developer Azol and the tablet developer Vedol, in the use of both of which they have helped the photographer by working out tables for development by time and temperature. Chemicals, such as iron perchloride and collodions, for process work, will also be shown, and the visitor will have an opportunity of seeing the results obtained by preparations for blue, green, red and sepia toning of prints.

Stands Nos. 32 and 33—Gevaert, Ltd.

The special feature of the comprehensive exhibit at this stand is the collection of prints on the new Vittex paper, of the chlorobrom variety for exceedingly pleasing brown-black tones by ordinary metol-hydroquinone development. The professional photographer in particular will be interested in these renowned results and indeed equally in those on the other varieties of Gevaert development papers.

Practically the whole of the exhibit is made up of specimens from negatives on the various grades of Gevaert plates, the Sensima ultra-rapid 500 H. & D., the Special Sensitive and the Professional Green Label. The amateur worker will turn to the work done on Gevaert gaslight and self-toning papers to that with the Filter Ortho plate, and to the transparencies on the Gevaert lantern plates.

Stand No. 34—Bean and Halliday.

As in previous years, this Yorkshire firm of mount makers will bring together a representative exhibit of their latest styles in mounts, folders, albums, and wallets. Their specialties include also all descriptions of mount, slip-in, etc., for amateur requirements; also calendars for photographers undertaking commercial work mounts for enlargements, and flexible art mounting boards are among their other manufactures.

Stand No. 35—Adhesive Dry Mounting Co., Ltd.

This pioneer Company's display of equipment and materials for dry-mounting includes presses for both professional and amateur use, and visitors will have the opportunity of witnessing constant demonstrations of the process. The latest type of visible trimming desk will be shown, and the exhibit will be completed by inclusion of a full range of mounts, loose-leaf albums and of border tints for the many effective styles of multiple mounting to which the dry-mounting process is specially applicable. The Company will also show and demonstrate a new small electric iron suitable for amateurs for the dry-mounting of prints from about 3 x 2 ins. to cabinet size.

Stand No. 36—J. Lizars.

Among the many models of the well-known Challenge series of cameras, will be shown the most recent introduction, namely, a $3\frac{1}{4} \times 2\frac{1}{4}$ folding pocket camera for roll film and glass plates, requring no change of the focussing scale when using one or the other of these different sensitive materials. Messrs. Lizars will also show examples of the tropical models of cameras in which they have long specialised.

A new exposure meter will be shown in the shape of the Milner light-gauge, a very small and thin form of meter, in which an entirely novel principle is adopted, the light being gauged by reflection through a disc of tinted film. The exhibit will also include several models of Brunette home cinematograph projectors, taking films of the standard size. The light in one model is generated by manual operation of the handle which moves the film, others are provided with a small motor for the machine drive, taking their current for the lamp from the ordinary house supply.

Stand No. 37—Robinson and Co.

In this exclusively profesional exhibit—Messrs. Robinson undertake their work in enlarging and water colouring only for professional photographers—there will be examples of several new styles in coloured enlarged portraits. One of the choicest of these is that named the Ideal—a beautiful style of water colouring, with an appropriate line ruling around the portrait. Messrs. Robinson make a specialty of masked enlarging work on a single sheet of paper, and obtain some very striking and pleasing effects by the work of their colourists on the margins or backgrounds.

Another new series is the Barribal, both solid and vignetted in the style of this artist. Broad slashes of colour are used to produce a very decorative effect in either a light or a dark key, the style lending itself to portraits of both men and women and children. For men, Messrs. Robinson have another new style, the Vandyke, in which a brown background is worked in by themselves. Another new introduction is the Duchesse panel, a vignette with a cleverly-added background in wash. For portraits of children there are some examples of the firm's exceedingly clever work produced in a sketch style of 20 x 16 size, in which an appropriate background is added to the portrait.

Messrs. Robinson are also making a special study of masonic portraits in water colours, and show the very excellent effects they obtain in the rendering of regalia. Another specimen, containing the red robe of a mayor, shows also the effective use which they make of water colours.

A notable feature at the stand is a 40 x 30 water-colour portrait of a lady draped in ropes of pearls. For the effect five colours were used for each pearl, a sufficiently eloquent tribute to the craftsmanship and patience of the firm's staff. This and the other exhibits, some of which we have mentioned, should not be passed by without noticing the distinctive frames which Messrs. Robinson adopt for their work, and to which they are constantly adding new patterns.

Stand No. 38—Thomas Illingworth and Co., Ltd.

Two new Illingworth manufactures will be launched at the Fair. One is Illingworth roll film, negatives made on which will form a prominent part of the display. The other is a collodion self-toning paper, a variety of printing material which has not hitherto been made at the Willesden factory, but which has now arrived to take its place with the other

favourite papers, Slogas (gaslight), and Enitone (gelatine self-toning). Messrs. Illingworth have thus the satisfaction of emphasising to dealers that their manufactures now include the whole range of materials for the amateur worker, film, plates, and all varieties of printing paper.

At their large stand, so conveniently adjacent to the refreshment department, Messrs. Illingworth will also show a collection of big toned enlargements made on their Bromide De Luxe. Some of these are from negatives taken by Mr. T. Midgley Illingworth on his recent tour round the world: others are portraits by Mr. Herbert Vandyk, of Princess Mary and Viscount Lascelles and other members of the Royal Family, whilst the recent royal wedding is represented by an enlargement of a photograph of the ceremony in Westminster Abbey, from a negative taken by the photographic department of "The Times," on the Illingworth Super Fleet plate.

The merits of Illingworth panchromatic and studio plates, lantern plates, and other grades of dry plate, will also form part of the exhibit.

Stand No. 39—Wellington and Ward.

The introduction of a new Wellington printing paper is assuredly in itself an event of photographic importance. Messrs. Wellington and Ward will make the Fair the occasion to bring before the public a new development paper which they are calling Q-Tone. It is a paper yielding a rich warm black image, together with an exceedingly long scale of gradation by direct development. Professional photographers in particular will be anxious to make themselves acquainted with this new product from a factory which has provided them with so many plates and papers of the highest excellence in use wherever photography is practised.

A new edition, the twelfth, of the Wellington photographic handbook will also make its appearance at the Fair, with added chapters on cameras and the Bromoil process, and including instructions for the new Q-Tone paper which we have just mentioned.

As regards other items of the exhibit, it is hardly necessary to say that those delighting in prints, negatives, and transparencies of the highest technical quality will be able to see them in the shape of the specimens on the many Wellington printing papers, plates, and lantern plates.

Stand No. 40—Witt and Westley.

Mounts and mounting materials for the professional photographer are the customary exhibit of this firm, and will again be shown in the latest styles, demonstrating Messrs. Witt & Westley's long experience in the highest branches of this manufacture. Frames of inlaid wood and leather are also among the firm's specialties, and the exhibit will also include dry-mounting machines, the Weslem dry-mounting tissue, and Ivorex retouching varnish.

Stand No. 41—Raines and Co., Ltd.

Messrs. Raines are bringing together a powerful exhibit of their resources as high-class enlargers, artists and colourists for photographers. A striking item is a 54-in. sepia carbon enlargement, a full-length portrait of a lady on a staircase. Straight bromide enlargements, in black and sepia, have long been a specialty of the Ealing firm, which has rightly emphasised the great merits of such work if done as well as it can be done. One of these enlargements is a portrait of the late Sir Ross Smith. The firm's work in oil portraits on canvas, with and without photographic basis, will be shown, and also a series of specimens of its styles in water-colour portraits, including a new one 18 x 14 ins. in an oval frame. We are glad to see that Messrs. Raines are directing attention to portraits in pencil-sketch finish, a style particularly effective for studios whose customers can appreciate work of taste. The exhibit will incidentally provide a demonstration of the firm's artistic craftsmanship in mounting and framing, and will also include lantern slides and mounted contact prints in carbon, bromide and gaslight.

Stand No. 42—F. Brodrick, Ltd.

Equipment for the quantity development and printing of amateurs' films forms a chief part of Messrs. Brodrick's exhibit, and includes teak tanks and dishes of all descriptions, printing and washing machines, etc. The professional photographer will also find at this stand many of the dark-room and work-room accessories which are a specialty of the firm. As designers, builders, and fitters of studios, shops and works, Messrs. Brodrick welcome inquiries for contracts of this kind, and will have on view a selection of designs illustrating their experience in this field, and in particular in the artistic furnishing and decoration of premises.

Stand No. 43—Burroughs Wellcome and Co.

The special feature at Messrs. Burroughs, Wellcome's stan is a collection of 88 quarter-plate negatives, each developed with a single fluid oz. of developer made up from the firm's well-known "tabloid" Rytol, a demonstration of the efficiency and economy of this compressed developer, for the use of which tables for development by time and temperature are available and may be obtained at the stand. The exhibit will also contain enlargements from some of Mr. Ponting's South Pole negatives, in the making of which Rytol was exclusively used. The green tone of these enlargements is obtained by the "tabloid" green toner, and the exhibit will show the range of tones in lantern slides obtainable by the use of other "tabloid" developers and toners.

Stand No. 44—Anglo-French Photography Co.

As agents for the old-established firm of Grieshaber et Cie, this company will show a collection of artistic photographs made on the Grieshaber papers, and will show results obtained on the full range of dry plates issued by the French makers. There will be also on view a collection of stereoscopic views of war scenes on the French front, depicting a number of incidents in the actual fighting with more gruesome reality than has commonly been displayed in war photographs. It is claimed for these views that they are almost unique in their truthful representation of the horrors of warfare.

Stand No. 45—Ilford, Ltd.

As in previous years, the Ilford Company will bring together a great variety of exhibits of technical interest. The amateur or professional desirous of studying the different effects obtainable by variations of material or method of treatment will probably find a greater number of specimens repaying his attention at this stand than at any other. The range of tones from red to cold purple obtained by using different strengths of hypo bath with Intona self-toning paper, is one of these exhibits. Another is a somewhat similar collection showing the variation in tone obtained on the Ilford P.O.P. by simple dilution of the toning bath. In the case of the Ilford gaslight papers, the exhibit demonstrates the correct variety of paper to use for the printing of different classes of negatives, and also the range of tones obtainable from black to sepia or red.

The characteristically beautiful results in the shape of transparencies on Alpha lantern plates by simple development, with or without gold toning, should not be omitted by the slide maker, who may also observe the results on the more rapid Ilford Special lantern plates when metol-hydroquinone or pyro is the developer.

Naturally, an Ilford exhibit would not be complete without a demonstration of the Ilford negative plates, and particularly the panchromatic. Examples of the use of the latter in aerial photography will be shown, and also specimens of three-colour and orthochromatic work. Negatives on the ultra fast Zenith 650 H. & D. plate will also be shown, and the Company will include also such specialties of its manufacture as Desensitol, light-filters and safelights, and its new colourless Q filter for absorption of the ultra-violet.

Stand No. 46—E. B. Fry, Ltd.

In addition to everything for passe-partout and lantern-slide work, Messrs. Fry have quite a series of new introductions which will be shown for the first time at the Fair. Among these are several new specialties for passe-partout work. One of them is a passe-partout binder gauge, a neat device which quickly permits of the binding being placed on the glass of the passe-partout so as to give a perfectly even band, the width of which is exactly determined beforehand by setting the position of the gauge on its baseboard. Messrs. Fry have also some new styles of passe-partout binder in imitation of burr walnut and grained oak, these binding papers, especially when used in considerable width, giving an imitation of a wood frame. Gilt and pebbled white passe-partout binders of quarter-inch width are other new specialties, and still another is a convenient damper consisting of a water filled tube with its mouthpiece fitted with porous felt.

Messrs. Fry are also showing an entirely new pattern of film printing box, the special feature of which is the curved glass bed, on which the film negative is laid, the paper placed upon it, and uniform pressure obtained by drawing down a stout fabric apron which smooths out the printing paper and switches on the printing light as soon as it comes into its fully extended position. This printing box is supplied for use with ordinary current and, in an amateur model, for current supplied by a battery incorporated in the box. Two other printing novelties are spring-back printing frames, for development and print-out papers respectively. The former is specially designed for saving time in the dark room and may be adapted to form the top of a printing box; the latter provides a full view when printing on P.O.P.

A further new printing requisite is an orange mask for making white margin prints. A series of minute perforations are made parallel with the edges in the cut-out and serve as a clear and sharp guide when trimming the prints, and thus render the production of strictly "square" prints, with margins of exactly equal width, most certain and rapid. In addition, Messrs. Fry have some interesting novelties for the D. & P. business, and are also showing specimens of dry-mounting tissue which they are issuing in shilling and half-crown packets as well as in gross lots.

Stand No. 47—Iliffe and Sons, Ltd.

At this stand the publishers of our contemporary, "The Amateur Photographer," and of the series of numerous text books and manuals of photography, will have a display appropriate to the place which these publications occupy among photographic readers and students.

Stand No. 48—Jules de Gottal.

The manufacturers of the well-known French firm of Guilleminot, Boespflug et Cie will be shown at this stand, and will include the firm's series of dry plates, including the anti-halation variety in which a non-actinic transparent film is provided between the glass and the emulsion. Another notable negative-making material is the Guilleminot Folio-Brom, a stripping negative paper. Prints on bromide, gaslight, and P.O.P. papers serve to represent this side of Messrs. Guilleminot's business.

Stand No. 49—Mackenzie and Co.

The Mackenzie-Wishart system of carrying plates for exposure in envelopes, and the convenient slide by which one can dispense with a number of plate-holders, are so well known to many photographers that an exhibit of the appliances ought not to be absent from a gathering such as the Fair, which brings before the public the many and different photographic facilities which are available. Yet it is our experience that many of the more serious amateurs are not acquainted with this system; they should, therefore, take the opportunity of making themselves familiar with it.

Stand No. 50—All-British Photographic Competition.

At this wall space, as at many of the stands in the Fair, prominence will be given to the £3,000 competition, which is being held during the present year for photographs made with British cameras and with British materials. The competition is for prints from negatives on dry plates, a branch of manufacture in which makers in this country have, by common consent, been pre-eminent in the markets of the world. Full particulars and entry forms for the competition will be obtainable at the Fair at the stands of any of the promoting firms, *i.e.*, Messrs. Butcher, Elliott, Griffin, Houghtons, Ilford, Illingworth, Kosmos, Leto, and Wellington & Ward.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

(We begin in this issue the publication of a series of chapters by an eminent portrait photographer, whose identity is somewhat thinly disguised by the pseudonym which he has chosen. Although the business side of photographic portraiture is a subject on which much can be written to the advantage of those less liberally endowed by Nature with the business instinct, it is rare in our experience to find one of the leaders in professional portraiture coming forward for the instruction of his brethren. The present introductory article is general in character. Succeeding chapters will deal more specifically with the relations of the photographer to his client, with systems of book-keeping and costing, and with the art of collecting accounts. Our contributor has a lively style in writing and it may, therefore, be hoped that the series of papers will obtain a close reading from those engaged in the business carried on in photographic studios.)

I. THE ECONOMIC POSITION OF THE PHOTOGRAPHER.

Firstly, I must apologise for the sub-title of this first chapter. It is both crude and commercial, and not at all in harmony with the tone in which any really high-class photographic studio is conducted. To suggest to an artist that he occupies an economic position is almost as bad taste as that of a certain noble lord who takes pleasure in pointing out to eminent and justly ruffled portrait painters that the value of their work is assessable at a price per square yard. Nevertheless, the professional photographer who balances cash, renders accounts, and performs other mundane but highly necessary duties, is a person conducting a business, and as such he occupies a very definite place in the world of commerce and economics.

It may be taken that all photographers realise their social position in the community. One can see this by the advertisements of "Studios for Sale." They are all either "High-class Studios," "Middle-class Studios," "Post-card Studios," or "Lock-up Studios"—whatever this last term may mean. Evidently a studio which will lock is the lowest type of studio obtainable.

What, I venture to suggest, however, is, that the average professional photographer does not usually realise the actual economic position which his particular business occupies, and consequently he is unaware of the advantages, disadvantages, or the ultimate possibilities of his particular studio as a source of revenue.

For the sake of simplicity we shall imagine the case of a studio which is of good average class—not one which is unapproachably exclusive, nor yet one which merely makes a profit on wages and materials; for this latter class of studio is really akin to any retail trader dealing in a cheap luxury, and the economic problems of such a photographer are not really coincident with those of the higher classes of studio. The position of an average good-class photographer is, therefore, as follows:—His portraits, besides being luxury articles, are commodities of which there is necessarily a very limited consumption. No matter how cheaply he may offer his goods to the public, nor how wealthy his public may be, photographs are of use to them only once in a period of years—and then only in a very limited quantity. After I have been photographed, have ordered, say, two dozen, and have distributed these among my friends, I am not inclined to order further copies of the same portrait unless they are offered to me at a very much reduced price. Supposing, however, that I am weak enough to do so, and I order a third dozen, any photographs in excess of that number will probably be not only worthless to me, but a nuisance. They would merely occupy cupboard space in my house, and would become what the economists term a "disutility." And these conditions will last for a period varying from five to twenty years, according to the extent of my personal vanity.

Now, compare this with the same individual's dealings with his baker. This refers to bread only. An individual consuming three loaves per week, at 10d. per loaf, would spend £6 10s. per annum. The photographer, on the other hand, may obtain scarcely that sum from one customer in a period of five years. Hence, if the photographer wishes to be as prosperous as the baker, he must obtain sufficient profit on his one quinquennial transaction to equal that of the baker during five years of daily custom. Further, the photographer does not always sell extra items such as miniatures and enlargements to each client; yet the baker sells regularly to the same customer many other articles which are a great deal more profitable than bread. Thus the baker may secure a steady and profitable business by having a limited number of customers who buy from him every day.

The recurring periods at which people are photographed vary, of course, in accordance with the rapidity of change in the person concerned. Children are therefore photographed more frequently than adults. Of the latter, women are more susceptible to the camera than men. In their case, however, it is their clothes which change. They themselves endeavour to remain as unchanged as possible, and it is the business of the gallant photographer to assist them in this. As for men, it is well known that they rarely enter a photographic studio save in order to terminate a feminine persecution. Men are in the habit of affecting an enormous contempt for the idea of being photographed. They enter the photographer's reception room with an air of apology for doing anything so vain and so effeminate. Creatures, however, who accept knighthoods and O.B.E.s with gratification, or who can listen with smug self-satisfaction to the magnification of their own abilities in an after-dinner speech, need have no fear that either their modesty or their manliness will be tainted in a photographic studio.

If, then, the photographer cannot increase the sale of his product to the individual, what other resources has the poor wretch who may harbour visions of one day possessing a sufficient fortune wherewith to retire from business, buy an estate, and become a gentleman? He has no other course but to increase the number of his customers. To a merchant or manufacturer this normally presents no great difficulties. They say to their minions: "Let us now send our travellers abroad, and open up an international trade." Or, "Let us issue a catalogue, and sell our goods through the post." But the poor photographer cannot do either. His customers must come to him in person. He may consider the hiring of an operator whom he could send to scour the country. But this involves heavy hotel expenses and train fares, which would probably absorb all his profits. Thus, a photographer situated in a small town may with difficulty achieve a comfortable retirement, but he can never hope to purchase either the estate or the gentility.

This brings us to the question of locality, a factor which, in the teeth of all the disciples of tone, composition, double, treble, or quadruple lighting, I hold to be the most important in the successful conduct of a photographic business. It takes undoubted precedence over capital, and is the *sine qua non* of financial success. First, however, we must appreciate the true meaning of rent, the underlying reasons why rents vary in different localities, and why, in short, one pays rent at all. The apparent reason is not the real one.

Let us imagine, for example, a small village possessing only one street, and let us suppose a shop-keeper sets up a business there. There will exist at first a certain moderate demand for his goods, and the price which he will be able to obtain will be relatively low. But the community increases, and gradually side streets are built adjoining the main one. Our shop-keeper now finds the demand for his goods to be increasing, and he is able to obtain a more satisfactory profit on each article. Now let us suppose that a second shop-keeper, possessing equal ability and capital, comes to the village, sees that it is a growing one, and sets up his business in one of the side streets. Previously, one shop was sufficient to supply the needs of all the village, and it would not have been profitable for this second shop-keeper to have commenced business there, but now the village is of such a size that this has just become possible, and the second man opens his shop, and charges somewhat less for his goods than his competitor in order to encourage custom in his side street.

At this stage the landlord of the first shop approaches his tenant and points out that here, in the same village, is a second shop-keeper, evidently possessing equal capital and ability, and who is apparently making a satisfactory living. "Yet you," he adds, "are making much higher profits than he. What is the reason of this? It must be solely on account of the premises which you occupy. As these desirable premises are mine, I must ask you to hand over to me each year those surplus profits which you are thereby able to make." Thus the premises of the first shop-keeper yield rent.

Similarly, as the community increases still further, and the demand for goods becomes still greater, a third shop-keeper may arrive on the scene and set up business in a still less favourable locality. Provided he, too, can make a reasonable living, the business of the second shop-keeper will be found to yield a surplus over that of the third, and he, too, will be required to hand over that sum to his landlord.

This method of viewing one's rent in the light of a surplus created by reason of the premises—and not as an expense deducted from a hard-earned profit—is a very comforting one.

My reason, however, for thus dragging my readers through the morass of an economic theory is to point out an important fact connected with professional photography. If rents were always assessed according to the surplus created in each case, this world would be a happier place. But as, in practice, the rent of each building tends to be a fixed one, and as, also, the amount of capital and personal ability possessed by different tenants tend to vary, it becomes possible that the same premises in the hands of a new tenant may be found to produce a very much smaller surplus than should normally be created. Thus the wretched tenant is compelled to hand over each year a sum of money which is not surplus at all, but a part of his private earnings.

This may be the result of subnormal ability or capital on the part of the tenant, but it may also be on account of the unsuitability of the kind of business to the premises. Now, a photographic business is a peculiar one, and because a certain surplus or rent has been yielded under the occupation of any other type of business dealing directly with the public, that is no criterion as to the surplus which a photographic studio would create. This law is evidenced by the fact that it is only in the suburbs or in small towns that the use of a shop or ground-floor premises is an economic possibility for a photographer. Few studios in fashionable or central localities can afford such a luxury.

The average trader who occupies a shop gets continuous custom all day and every day; the photographer only intermittently. These unused intervals yield no rental surplus. On the other hand, it would be equally impossible for the shopkeeper to carry on his business successfully in the photographer's upstairs premises. And here the photographer gains. Such premises being usually assessed at their probable value to a purely commercial firm, and not with a view to their occupancy by a photographer, the rental surplus which the rooms yield to him is really greater than that which he is required to pay to the landlord. It is, of course, unnecessary to inform one's landlord of this fact. So long as the photographer possesses space at his doorway in which to display his work, that is all the street publicity which he requires. The woman who espies an article of clothing in a shop window, and conceives a desire for it, enters the shop and makes her purchase —frequently on the spur of the moment. If she were obliged to climb a stair in order to do so she would probably return home without the article. Her portrait, on the other hand, is a premeditated act. It is preceded by an appointment, and after due consideration.

Linked with the obvious advantages of a well-populated area to a photographic studio is the extraordinary magnetic effect which such an area seems to exercise over persons not living in it. Thus a provincial photographer is not only faced with the difficulty of maintaining himself out of the precarious patronage of a thin population (in the numerical sense, of course), but he has the additional hardship of witnessing much of what should be his custom drawn London-wards, or to a larger town, or to a more fashionable district than his own. The public will not listen to his arguments, which are obviously the outcome of a natural but provincial jealousy; and they themselves have their gaze turned toward what they consider fashionable, with a paralytic fascination similar to that of a hen with its head on a chalk line.

The reasons for the super-normal financial success to which, for instance, a west-end London photographer may attain, are therefore obvious. He has not only a very large population at his disposal, wherewith he can multiply the comparatively small individual consumption of his product, but he has also the advantage of an enormous floating or visiting population not counted in the census returns. All these people "up from the country," are possessed of money saved, maybe for months, in order to "buy it in London." No matter if they pay double the provincial price for less than provincial quality, they will proudly show the article to their secretly envious friends, saying "I got it at So-and-So's—in London, you know." Or, if they have passed more than a week or ten days in the metropolis, they will probably call it "Town," having acquired the language.

For all these advantages of locality the London shop-keeper has to pay very sweetly in rent. But, as already pointed out, the photographer, in his upstairs premises, gains more from good locality than he is required to pay for. Hence, a west-end London studio should make more profit in relation to capital and personal ability than any other.

All this is very galling to the provincial photographer, who may not possess sufficient capital to remove his business to so coveted a position. On the other hand, he should bear in mind for his comfort, that there must be many photographers in London who could not scrape a living in the provinces. To this the London photographer replies: "Who wants to?" And there the matter rests.

Next in importance to locality comes the social status of the studio. This depends entirely on whether one wishes to dispense art at a high figure, or photographs at a low one. Both now form an equally precarious means of livelihood. As a choice, however, between two methods of attaining to poverty, it is perhaps better to favour the former, and to grow poor on art. There are, of course, definite limits, in any one town or district, beyond which it is not possible to rise in the social altitude of one's business. In a large community such as London or New York, for example, a photographer may betake himself and his camera to a private mansion, fix a brass nameplate at his door, charge ten guineas per dozen, and become, like Pooh-Bah, a very exclusive gentleman. In less populous areas, however, this is economically impossible. One can be a gentleman, but not exclusive. Like the geometrical point, such a firm would have position, but no magnitude.

The third factor, and next in importance, is capital. This, fortunately, does not need to bear so high a relation to profit as is the case in other kinds of business. Its use, in fact, in a photographic business is very limited. To a man who buys and sells goods, capital is everything, because the more he possesses the more goods he can buy and sell. To the photographer, however, after he has furnished his premises, bought his apparatus, procured a reasonable stock of materials, and placed a certain sum in the bank, extra capital is useless. So long as he remains in that locality, and conducts a business of that particular class, any amount of surplus capital will never increase his profits. This is another point in which photography seems to differ from almost all other kinds of business.

Fourthly, we have personal ability. In this case I refer to artistic ability. To those who would challenge me for placing this factor last, I would point out that this article professes to deal with only the business aspect of photography—that aspect which measures success by net cash returns. And as there are so many photographic firms who, up till recently, used regularly to produce substantial profits, and who showed no evidence of artistic abilty at all, this factor in professional photography must have very little importance indeed. Certainly, art in a man's portraiture will not be observed by the public if his studio is rented below a certain figure. Thus we have the woeful corollary that a brilliantly artistic photographer in the provinces, or in a suburb, is an example of a wasted life. However great a genius, he can never achieve more than a local fame. His work may be well known throughout the country, or the world, to those who frequent photographic exhibitions; but to the general public he is born to blush unseen, and waste his art upon suburban air.

If, however, we take personal ability to mean "ability to please the public," then the position of such a photographer is briefly as follows: Since he has found some means of satisfying the local public taste to a greater extent than his competitors, he will be able either to charge higher prices or he will create a larger clientèle. This means that he will make larger profits than his rivals, although they may be equally well placed as regards locality, capital, and class of business. The surplus profit which he thus makes is, therefore, another form of rent; but the result, this time, of his own exceptional abilty. This, which is known in economic parlance as quasi-rent, belongs to the man who creates it, and not to the landlord.

This very just law is, unfortunately, influenced to the bad by that tyrant, locality. The local public, as already explained, will flock inevitably to the more fashionable district or town; and while such a photographer will always reap a certain reward for this special ability, he will never gain the reward which is really his due unless he improves his locality to the maximum. In this country this can only be achieved by removing his studio to the west-end of London. There he will obtain full credit for all his skill, as well as credit for much

that he never aspired to. He will yield to himself a maximum locality-rent, the fullest quasi-rent, together with the highest possible social-rent. All his work will be considered artistic, the public will breathe his name with awe, and his clients will flaunt examples of his portraiture in the faces of provincial photographers.

To borrow a line from "The Beggar's Opera," "Is there aught else on earth desirous?"

PELHAM SWINTON.

PHOTOGRAPHIC DEALERS' ASSOCIATION.

THE Annual Congress of the Photographic Dealers' Association will take place at the Photographic Fair, which will be held at the Horticultural Hall, Westminster, from Monday, May 1, to Saturday, May 6, inclusive.

Congress tickets will be issued to members. The cost will be 2s. each, and by the kindness of the promoter of the Fair, Mr. Arthur C. Brookes, the ticket will entitle the holder to admission to the Congress, and to the Fair at any time during the week.

The annual dinner will be held at the Holborn Restaurant on May 1. Ladies will be welcome. The dinner promises to be even more successful than the last. The reception will be at 6.30, dinner at 7. The dinner will be open to all interested in the photographic industry, including professionals. A first-class musical programme will be provided, and speeches will be reduced to a minimum. Tickets will be 10s. each.

At the request of members an outing has been arranged for May 3. Char-à-bancs will attend the Fair at 10.30 a.m. to convey the party to Windsor, where a lunch will be provided. After lunch a launch will be in readiness, and the party will be taken on the river to Marlow. This trip includes some of the most charming scenery on the Thames. Tea will be provided on the launch, and the char-à-bancs will take the party back to London. The cost of this outing, including lunch and tea, will be £1. Ladies are invited.

It is felt that this year's Congress is the most important one in the history of the Association. The very difficult conditions which have prevailed since it was formed in May, 1914, have naturally retarded its progress somewhat. Conditions are now happily, improving by leaps and bounds, and the Photographic Dealers' Association will become of more vital importance to the dealer every day. A good attendance at the general meeting will do more than anything else to encourage officers to persevere in their efforts to maintain and improve the photographic trade. It is, therefore, clearly in a dealer's interest to make a real effort to be present.

AN EXPERIENCE IN MAKING D. & P. TANKS FROM DRAIN PIPES.

THIS being the time when many photographers are busy opening up, extending, and generally preparing for the season's D. & P., the following experience which recently befell me may be interesting, and although I do not expect any reader to "go and do likewise," but advise a more cautious and premeditated policy, there may be something of practical value in what follows.

Through circumstances which need not be recorded, a certain business took a lightning decision to extend, in order to undertake a new contract, the extension necessitating the fitting up of new workrooms. As it happened, everything was at hand except a set of deep spool developing tanks. A perusal of manufacturers' catalogues brought to light tanks that were too large—and too expensive—and tanks that seemed a trifle small for the business in view, and all of them were many miles away, and no indication was given of whether delivery might be expected in two days or two weeks, or when. It was then that I remembered that an American photographer had made his own tanks out of drain pipes, but, of course, I could not find the particular issue of the "B.J." which described them in detail, so I set out to see what I could find on chance.

I soon found that the only common pipes were ridiculously small for the purpose in view, but there was a size *manufactured* (2 ft. 6 in. × 1 ft. 3 in.) which would just about do. At first it seemed that this size had never got beyond the manufacturer's premises, but at last I found a merchant who said he could supply at once. In the meantime I had made various inquiries about making bottoms for the pipes, and some had advised me to block the flange with wood, while others said slate and cement. I decided on the latter, with the addition of a layer of chicken netting for strength.

The pipes arrived. They were to be used on a floor which could only be approached viâ four flights of narrow stairs. They weighed over 1 cwt. each, and were about as wide as the stairs. But I will cut out the upstairs trip. We got them up—eventually. Then two of us set about cutting the slates. Not being *au fait* with the slate-chipping art, we drilled holes at half-inch intervals before attempting to break. It looked easy, but that was all. Next the cement. We calculated that about half a stone would do the lot, but those flanges swallowed over a stone each, and then yawned for as much again. With the wire net buried in a 1½-inch layer we gave it up and retired, myself to dream that it was a busy summer day, with still 200 spools to go and the tank bottom dropping from under the metol-hydroquinone-pyro formulæ. Next morning we filled each flange with a T-piece of 3 × 1½ wood, and re-cemented the edges. Then I calculated for volume $\pi r^2 \times h$ with 277 cub. inches to the gallon, and 9 gallons to the lb., etc. Being somewhat fagged, I first calculated with πr^2, and, seeing the result, I sent out for timber to reinforce the floor. Then I discovered the error, finding the approximate volume to be about 14 gallons and the gross weight a little over 2 cwt. for each tank. The timber having arrived, we decided to use it, and with three 7 ft. lengths of 3 × 2 laid on their edges, 2 ft. apart, and covered with cross-pieces of ¾-in. floor-boarding, we spread the total weight over 14 sq. ft.

The next day we filled the tanks. Since then they have been emptied once—syphoned with rubber tubing to an outlet in the wall at a lower level than the inside tank bottom—and the bottoms examined. Apparently there had been no cracking or leaking, but in spite of this seeming success, if I did another I would first consult a good text-book on cement. One authority advised me to give it half an hour to set; another said a day; another, two days; another, four. Some thought it wanted sand; some that it must be very wet. I tried to steer a middle course, but, in face of the differing opinions, I felt uncertain about a very important point.

The necessary rods, which had to be of varying lengths on account of the curvature of the pipe, were cut from copper wire and well silver-plated in used hypo solution. One pound of wire made two sets, each rod having a dip of 3 inches.—D. P.

FORTHCOMING EXHIBITIONS.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 26, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography." Open daily from 11 to 5 p.m. 35, Russell Square, London, W.C.1.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries by carrier, August 25. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Mask Making.

The following method is a very quick and efficient way of making paper masks which are at the same time strong and neat. Mark out on a piece of black paper the size of opening required, then cut it out roughly about a quarter of an inch larger all round. Obtain some lantern slide or passe-partout binding, and fill in the unnecessary part of the opening. It is best to use two layers of a thin binding rather than one of a thick variety.

In ruling out the opening required continue the pencil lines to the edge of the paper, this serving as a guide for placing the binding in position.—A. W. Woodmansee.

On Not Waiting for Business.

Much is written nowadays about encouraging public interest in photography, but the line taken usually by our class is that of the doctor who cannot seek publicity beyond having his name-plate outside his surgery. Why do we not force ourselves on the public as the manufacturer who has goods to sell, and knows their value to the extent of sending out his commercial travellers to push his lines. Surely photographers believe in the value of the articles they offer? For too long has professional etiquette stood in the way of photographers really reaching the public. Why should not the proprietor of a business, or the chief assistant, too, in these slack days, go out with the idea of looking for business? Much might be cultivated by offering suggestions to the public. A row of shops is being demolished and a large warehouse will shortly be in course of construction. Would it not interest those shopkeepers to have, perhaps, their first, but certainly their last photograph of their premises? The contractor for the demolition, the builders of the new premises, the fitters of shop windows, all should be approached, and suggestions should be made. They may be only too glad to hear them, and by all means leave them examples of similar work done by you, with your address. Persist in calling if your first approaches are not successful. A business man likes to see that you are dogged.

No effort should be spared to find business in these quiet times, and measures that were turned down as not worth while in normal times should be given a trial. Anything that helps to clear establishment charges should be considered. A certain business has made a remarkable success of copying photographs and making enlargements of people deceased, and this has been built up by obtaining details from local papers in the outskirts of a large town, of visiting the addresses of the relatives after advising them by postcard, and then gaining their confidence by showing work already done, and refusing any payment until the work is returned completed. This is now a very successful business, and very fully justifies the forethought of the method of looking for business, and not merely waiting "for something to turn up."

On the subject of copying, how often is this held up as a most difficult business, and although photographers do not point blank refuse it, such a price is put on it as to prove prohibitive, and with the object of discouraging the work. Yet it can be made to pay an assistant's wages, if interest is taken in it, and the work is encouraged, and cultivated. While on this subject, it may be mentioned that many people on their annual seaside holiday, have their photographs taken, and very frequently soon after their return take a copy to a local man for an enlargement. What opportunities the seaside photographer is missing here. A month or so after the holiday season has slackened, or towards Christmas, when trade is slack, a judiciously worded letter in the personal strain, sent to the people reminding them that an enlargement would revive pleasant memories might be sent to the home addresses of those clients, together with a postcard copy of the original photograph. In many cases, this would be productive of business.

A further sphere for activity is amongst the clergy, for as a class they are very shy of the studio, and many only visit it under pressure, when a bazaar is to be held, and their photographs are wanted for sale "towards the cause." Many clergy dabble with photography, and this kindred interest at once established a welcome to the photographer calling on the clergy. There are many cases where a good connection has been built up, for not only were the photographer's efforts appreciated in portraying events in the parish, such as groups of choir, clergy, scouts, guilds, and societies, but much work was afforded in doing lantern slides from a series of negatives to illustrate lectures, and the photographer was recommended amongst other clergy. All these circumstances help to the building of a connection, and cannot be ignored.

The object of calling attention to such matters is to ask the photographer to go about with an eye for business. There is a case of a large combine opening out many branches in a large provincial city. Many shop-fronts were altered where premises had been acquired, and an amateur photographer seeing the chance of using some of his spare time, secured the work of supplying photographs of all the branches. On occasions of special dressing, such as at Christmas, he is regularly asked to photograph all the windows, and a very good result has accrued from his seeing eye, which led him to interview the secretary and secure the job.

In conclusion, look about you, encourage the assistants to bring in their ideas, and where there are six pairs of eyes on the look-out for business, there will be more fruitful results than where the method prevails of waiting in the studios for brighter days. There is business, go out, and suggest it, and then you will secure it.—H. J. K.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 10 to 13:—

Cameras.—No. 10,219. Photographic cameras and view-finders therefor. H. Bishop and W. Langdon-Davies.

Cameras.—No. 10,705. Photographic cameras and printing-apparatus. H. R. Eason.

Printing-out Paper.—No. 10,363. Photographic printing-out paper and prints made therefrom. J. A. Johnson.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Kodak Tested Chemicals (Design).—No. 421,047. Photographic chemicals. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials. November 30, 1921.

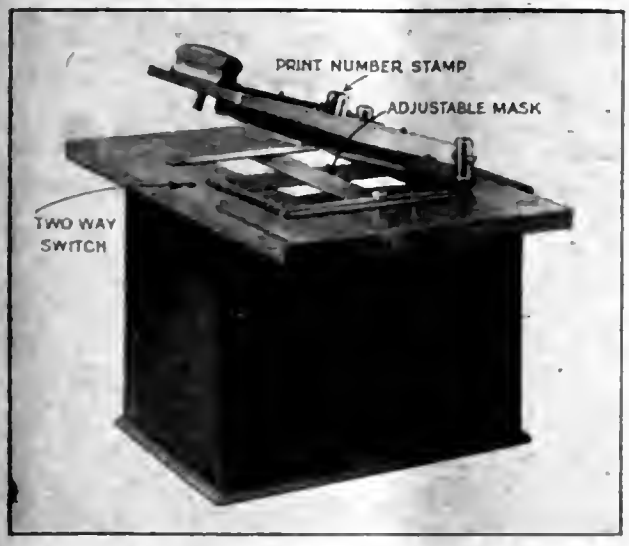
Photographic Test for Old Masters.—It is stated in the daily Press that photography has proved the authenticity of Rembrandt's picture, "The Good Samaritan," which is in the Wallace Collection, and said not to be a genuine Rembrandt. Professor Laurie, of the Heriot Watt College, Edinburgh, whose work in deciding on the authenticity of pictures by taking enlarged photographs of portions of them has already been described in our pages, was consulted. He took photographs of part of the picture, and compared them with photographs of other pictures known to be the work of Rembrandt. "The photographs show the identity of the brushwork in the two pictures," he told a "Daily Mail" representative. "It is not possible for the magnified brushwork of two different painters to agree so closely."

The Cinema as a Teacher.—A congress is being held this week at the National Arts and Crafts Institute in Paris to consider the possibilities of instruction by means of the cinema. The Congress, presided over by M. Gaston Vidal, Under-Secretary of State for Technical Education, is dealing with the cinema as an aid to the choice of a profession; technical, industrial and agricultural education, and artistic education, this section being organised under the anspices of the Council General of the Seine and the Paris Municipal Council. Experts connected with the development of the cinema have been invited to take part in the Congress; more than 500 have consented to give the Congress the benefit of their experience. Among those who will address the meetings are M. Louis Lumière, one of the pioneers of the cinematograph.

New Apparatus.

The XL. Film Printer. Made by Brodrick, Ltd., 50, High Street, London, W.C.2.

THIS printing box for single or band film negatives is now supplied by Messrs. Brodrick at the reduced price of £7 10s. The metal box is provded with a most substantial oak bed, measuring 20 x 13 inches, and fitted with a pair of masks adjustable to negatives from the very smallest size up to the full half-plate taken by the machine.



The pressure back, operating the lamp switch is most solidly made in the shape of a metal framework, on which the wooden pressure back proper is spring mounted. The latter is fitted with an automatic numbering device by means of which a series number may be impressed on the back of each print which is taken off. It is a thoroughly well made piece of apparatus.

Eastman Portrait Diffusion Discs. Made by Kodak, Ltd., Kingsway, London, W.C.2.

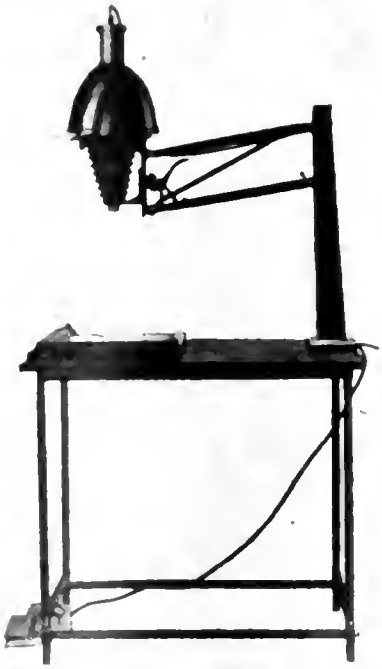
WHEN the ingenious plane-parallel "light-filters" were introduced at the same time as the first model of the Eastman Projection Printer, for the purpose of introducing certain degrees of diffusion into the enlargements made with that instrument, it was natural to assume that similar "diffusion discs" might be employed on camera lenses for introducing a certain degree of softened definition into the negatives made with anastigmat or other lenses. As long

ago as August, 1920, we published an article by Mr. C. W. Frederick, the inventor of the discs, in which it was stated that those fitted to the enlarger were, however, not found suitable for camera use in the making of negatives, but that further experiments were in progress for the purpose of devising filters of a suitable kind. These have now been placed upon the market, and are seen to consist of what are apparently plane-parallel glass discs provided with a series of extremely slight corrugations in concentric circle formation. In the case of the enlarger discs, these corrugations were in star form. The discs for camera use are made in two types—A and B—the former exercising a very slight softening of the definition; so slight, indeed, as to retain in considerable measure the sharpness given by the lens to which they are fitted. The B type gives considerably more diffusion, but even in its case the effect would by no means be called "out of focus." On the other hand, it corresponds with a degree of moderate diffusion somewhat resembling that which is obtained by a moderate employment of the diffusion adjustment of a Dallmeyer patent portrait lens. Prints made with the filters of both types show that the softness of definition is obtained without any sacrifice of the brightness of contrast resulting from the prevailing conditions of lighting and exposure of plate.

It is scarcely necessary to point out that many possessors of large anastigmat lenses will welcome these discs as a most convenient means of obtaining negatives of soft definition when the subject or the fashion of the moment renders such quality desirable. Again, many a photographer of modest means feels himself compelled to obtain one lens for both studio portraiture and such outdoor work as groups or architecture. For the latter he must, perforce, have a lens giving sharp definition, and hence the facility of obtaining soft focus in his studio negatives when he so desires is one which will substantially add to his resources. Each type of disc is made in two sizes—No. 1, of 3½ inches diameter, price 34s.; and No. 2, of 4½ inches diameter, for 43s. Adjustable disc holders, for fitting to the hood of the lens, are supplied in two sizes, No. 1 for lens hoods from 3 to 4½ inches diameter, price 23s., and No. 2, for lens hoods from 4½ to 5½ inches, price 29s. 6d. Those in London during the Fair Week may be interested in the intimation that the discs may be tried in the studio of the Kodak Co. in the Kingsway building.

The Kodak Projection Printer. Made by Kodak, Ltd., Kingsway, London, W.C.2.

THIS apparatus is a smaller model of the Eastman Projection Printer, possessing the characteristic features of vertical build and self-adjusting focussing of the latter, but differing in a number of



minor respects appropriate to the special work for which it is designed, namely, the enlargement of amateurs' negatives, either film or glass. The apparatus takes negatives up to and including 5½ x 3½ and 5 x 4 inches, from either of which enlargements may be made on any scale from 1½ to 6 diameters. The ingenious self-focussing adjustment by a cam mechanism, introduced in such refinement in the Eastman Projection Printer, is employed also in this apparatus with certain facilities added. One of these is that the two arms of the link work which support the camera and light-box work sufficiently stiffly to render unnecessary any locking of

the apparatus in any position. Thus the operator simply raises or lowers the camera, according to the degree of enlargement, and it "stays put" in any position. Another feature which is new in this model is a very ready adjustment by means of a toothed wheel for the initial setting of the enlarger.

The camera is fitted with universal masks, providing a truly rectangular masking of any size, for the production of white margin enlargements. For one of these masks, namely, that in the position which renders it liable to be shifted, a lock is provided. The negative carrier has a clip for holding a film negative in position, and also a sliding pointer which serves to permit of a whole series of small negatives of the same size being placed in the same position in the carrier so as to obviate alteration of the setting of the easel or paper carrier. The apparatus, although apparently of most simple construction, actually abounds in little devices such as these for the saving of time and labour. Illumination is by a 200-watt Mazda lamp, and the camera is fitted with an *f*/6.3 anastigmat. The whole apparatus is of the best in design and construction, and will come as a boon to individual producers of enlargements from amateurs' negatives. The price complete with lamp and lens is £50.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, APRIL 30.

Hammersmith Hampshire House P.S. Outing to Egham.

TUESDAY, MAY 2.

Royal Photographic Society. "Reproduction of Pictorial Work." E. L. Turner.

Bournemouth Camera Club. "Amateur Photographer" Prize Slides, 1921.

Cambridge Photographic Club. "Paget Process of Colour Photography." C. B. Coulson.

Hackney Phot. Soc. Annual Dinner.

WEDNESDAY, MAY 3.

Croydon C.C. "The Story of a Photographer with Two Lenses." A. Dordan Pyke.

Rochdale A.P.S. "Home Portraiture." T. Crabtree.

THURSDAY, MAY 4.

Gateshead Camera Club. Annual Meeting.

Hammersmith Hampshire House P.S. "The Story of the Photographer with Two Lenses." A. Dordan Pyke.

SATURDAY, MAY 6.

Hammersmith Hampshire House P.S. Outing to Barking Creek.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 25, Mr. E. W. Mellor in the chair.

The first part of the proceedings consisted in the annual general meeting of the Scientific and Technical Group. Mr. O. Bloch read the report of the committee, briefly reviewing the meetings which had been held, and the inauguration and publication of the Group's valuable work, "Photographic Abstracts." On the proposition of the chairman, seconded by Dr. Slater Price, the report and balance-sheet were adopted. The result of the ballot for the election of committee of the Scientific and Technical Group was:—Messrs. O. Bloch, H. W. Greenwood, K. C. D. Hickman, J. W. Grundy, and S. Read.

Mr. Mellor then vacated the chair in favour of Mr. Dudley Johnstone, who first declared open an exhibition of prints by Colonial readers of the "Amateur Photographer."

He then called upon Dr. Slater Price to deliver a lecture on "Gelatine."

Dr. Price read a most interesting paper, illustrated by a great number of experiments, describing the present state of knowledge of the properties of gelatine, as ascertained from modern work in colloid chemistry. He provided an introduction setting forth and illustrating the properties of the two different types of colloid, suspensoid, and emulsoid, and dwelt at length on the character of gelatine as an amphoteric substanee, namely, one which functioned as an acid toward bases and as a base towards acids. He gave, in popular and extremely lucid form, an account of recent work, done chiefly in this country, Austria and America, which had contributed to a better knowledge of the chemical and physico-chemical properties of gelatine, showing how some of the apparently anomalous results of earlier investigators had recently been made plain. He concluded with a discussion of the processes which take place in the hardening of gelatine.

A short discussion followed, in which Messrs. Storr, Hickman, and Grundy took part. On the proposition of the chairman, a most hearty vote of thanks was accorded to Dr. Slater Price, and to Mr. Rawling, who had performed the many experiments, not one of which failed to "come off."

CROYDON CAMERA CLUB.

Mr. F. C. Reynolds, who has made light and colour a special study, read an instructive paper on "Some Aspects of Colour Vision." As is his wont, many pretty and striking experiments were shown, nicely interspersed between more solid matter.

Little had direct bearing on photography, save a consideration of screen-plates, and some artificial equivalents of daylight, which are selected for brief notice. Daylight, he pointed out, is obviously not constant in spectral quality, and an average north light is adopted as the best standard, if somewhat a loose one.

Wratten's dyed gelatine filters, for use with metallic filament lamps, were shown. Edison and Swan employ suitably coloured glass for the bulb, and claim a loss of only 35 per cent. of the light emitted by the glowing filament, a claim, in the lecturer's opinion, which certainly errs on the side of numerical modesty. Messrs. Chance also manufacture sheet glass coloured to transmit only rays approximating daylight. In the Sheringham system a reflector is used, which reflects the colours wanted, whilst absorbing the excess of those which require damping. The illumination by this method is, however, materially reduced.

Among many other diversions was shown the "Plastograph." Spectacles fitted with one red and one green gelatine filter throw into stereoscopic relief two overlapping pictures similarly coloured. Mr. Reynolds was lucky enough to pick up the pictures from a stall in Farringdon Market for a penny apiece, securing a fashionable reduction in price by pointing out they were evidently throw-outs, as the faulty registration indicated.

In the discussion, which was contributed to by many, Mr. Hibbert mentioned that successful Autochrome portraits had been taken with artificial illumination. An enclosed electric arc was employed supplemented by two high candle-power half-watt lamps, one with a Lumière "Virida" green filter in front. The respective distances of the half-watt lamps from the sitter were determined by trial and error, their positions being varied till true colour representation was obtained. A most hearty vote of thanks was accorded Mr. Reynolds with much acclamation.

The club's Easter outing was held on the Monday, and proved a great success, despite distinctly nippy weather conditions. The Leatherhead district was visited, and things warmed up mid-day at the "Running Horse" at Mickleham, from where the party emerged full of enthusiasm and high resolves. Two teas were subsequently indulged in, and it is believed some photographs were taken. Reserved carriages in the train both ways gave the customary feeling of superiority over the cheap tripper.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The Council of the Association met at 35, Russell Square, on Friday, April 21, Mr. A. Corbett in the chair. There were also present the President (Mr. A. Swan Watson), Messrs. Marcus Adams, Angus Basil, A. Bennett, Frank Brown, W. B. Chaplin, Chas. Dickinson, W. E. Gray, Gordon Chase, H. A. St. George, George Hana, R. Haines, W. Illingworth, R. Lang Sims, F. G. Wakefield, W. Wedlake, and the Secretary (Mr. Alfred Ellis).

Apologies for absence were received from Messrs. Spink, Chidley, Chapman, Lambert, Wheeler, and Speaight.

The Secretary reported that he had received a letter from the Royal Photographic Society referring to the Fox Talbot Memorial Fund, and stating that the Society would gladly welcome any assistance. He had replied that he was afraid the Association could not do very much without the consent of the members at the general meeting, and suggesting that an appeal from the President of the Royal Photographic Society would be more effective than any he could make.

The Secretary also reported that the President of the Royal Photographic Society had written inviting the members of the Association to visit the Society's exhibition on Friday, September 15, from 11 o'clock to 5 p.m., and on Saturday, September 16,

from 11 to 1. The Secretary said he had written saying he was sure the members would much appreciate this kind thought. The exhibition would practically open when the Congress closed.

The Chairman remarked that they were largely indebted to Mr. Adams and Mr. Lambert for this concession, which the Council much appreciated.

The Secretary read a letter from the Editor of "La Photographie" referring to the centenary of photography, to be held in Paris in 1924, and asking for support. He had written saying he was sure they would do what they could, and inviting their friends across the Channel to come over and visit or send exhibits to the Association's Congress.

A Problem of Copyright.

The Secretary reported that a member had written asking for advice as to copyright. He took photographs of the child of a lady friend, not charging for the sitting. The mother bought some of the prints, and held that it was not a free sitting, as she had wished the child to be photographed. He now wished to dispose of the negatives to a firm of paper manufacturers.

The Secretary suggested that in this case, as the mother bought copies, the photographer could not claim the copyright. The member had replied that, to avoid any unpleasantness, he would not dispose of the negatives. The Council confirmed the action of the Secretary in the matter.

The Secretary read a letter which had been addressed to the President by the London Press Exchange on the subject of co-operative advertising.

The President said he had replied that at present the Council had too much work on hand to consider the subject fully. The suggestion was that professional photographers should combine in a scheme which would increase the demand for portraiture. Mr. Sykes had had a wide experience of collective or association advertising, and by his schemes had greatly increased the consumption of various articles. The President added that Mr. Bell, Editor of the "Professional Photographer," had written to him saying he could give some remarkable figures as to how co-operative advertising had improved business in America.

Mr. Basil observed that a good case had certainly been made out for some such scheme.

Mr. Bennett agreed that if a good scheme was adopted the demand for portraiture might be greatly increased.

Mr. Chase said a great many more men would be photographed for business purposes if the necessity was only impressed upon them.

Mr. Marcus Adams pointed out that six months previously he was asked to make inquiries as to the possibility of such a scheme, but, owing to the pressure of business, he had held it over. He feared it was hopeless to carry out such a scheme unless they had two or three thousand pounds for the purpose. And many of them would be willing to put down £10 without knowing more about it. He had worked out a simple scheme which, when the right moment came, he would ask them to consider.

Mr. Basil thought they could do nothing in a hurry. They needed first of all to impress the idea on the members generally.

Mr. Illingworth moved that some expert should be invited to give a paper containing information on this matter.

Mr. Adams seconded, and the motion was carried, the matter being left in the hands of the Congress Committee.

It was further agreed that the Secretary should write confirming what the President had already written as to the impossibility of dealing with the question until after the Congress.

Mr. Wakefield called attention to an advertisement in a newspaper in which a trade enlarger said, "We will help you to take good photographs. Call and talk over your photographic troubles." He strongly complained that this was taking the bread out of the mouth of the photographer for whom this trade house worked. The Chairman thanked Mr. Wakefield for bringing the matter forward, and said they would deal with it later on.

The Secretary read a letter from a provincial member in regard to a copyright problem. He was instructed to photograph certain original paintings, but the owners could not assure him that they possessed the copyright. The pictures were purchased before the last Copyright Act was introduced.

The Secretary said he had replied that under the old Copyright Act of 1862, when a picture was sold by the artist, unless at or before the time of selling an agreement was signed by the parties reserving the copyright, the copyright was lost. In the absence of an agreement the copyright lapsed and the picture could be copied by anyone. Under the new Act of 1911 the copyright remained vested in the artist unless he assigned it in writing to the purchaser of the picture.

There was useful information regarding copyright matters in the "P.P.A. Handbook," pages 16-33.

The Secretary read a letter from a member who asked for an opinion regarding his charges for special work away from his studio.

The Secretary had replied that it was difficult to answer the question without knowledge of his class of work. If he usually charged for outdoor work 10s. 6d. for a whole plate and finished proof, why not always charge in the same way, with travelling expenses extra? That was the usual way of doing it, although most firms charged a guinea for the first position, and half-a-guinea for extra ones.

In the course of the discussion which followed, it was suggested that it would greatly help members of the Association if standard rates could be published in the new "Record." Mr. Brown gave details of a case in which he was asked to take 12-in. × 10-in. photographs in a basement in which there were many mirrors. It was a long and difficult task, but the firm in question complained that his charges were too high.

The Chairman concluded the discussion by remarking that the important points raised would be debated fully as soon as possible. He hoped they would be able to help all members to arrive at a proper basis. In time no doubt they would be able to make standard charges for all classes of photography.

The Secretary said a letter had been received from a member who said he had had some trouble with his landlord under the Rent Act. It appeared he had been direct to the Association's solicitor, and the Secretary said he had informed him that as he had done that without any intimation to the Council, it must be considered a case in which payment would be between client and solicitor. He had written to Mr. Vaughan stating that if any member consulted him without any authority from the Council he was to consider it a private matter. Mr. Vaughan had concurred. The Secretary's action was confirmed.

Commercial & Legal Intelligence.

NEW COMPANIES.

R. W. Bell, Ltd. This private company was registered on April 18, with a capital of £500 in £1 shares. Objects: To take over the drug business carried on by R. W. Bell at South View, Forest Hall, Northumberland, and to carry on the business of chemists, druggists, opticians, dealers in photographic materials, etc. The first directors are:—R. W. Bell, South View, Forest Hall, pharmacy proprietor; Mrs M. G. Bell, 10, Briar Edge, Forest Hall; J. Scott, secr., 39, Windsor Terrace, Gosforth Northumberland, pharmacist. Qualification: 1 share. Registered office: South View, Forest Hall, Northumberland.

Royal Arms and Trade Marks Bill.—The text of the Bill to amend the Merchandise Marks Acts, introduced in the House of Lords before Easter by Lord Gorell, the Under-Secretary for the Air Ministry, was issued last Friday. It provides that where the Board of Trade are of opinion that a false impression as to the origin of any class or description of goods is likely to arise, the Board may make an order requiring an indication of origin—either of the actual country or of the fact that they came from outside the Empire—to be given by publishing notice of their intention in the "Gazette," giving all persons affected an opportunity of making representations on the point. A fine not exceeding £20 may be imposed under the Bill upon any person or association using in connection with trade without authority the Royal arms or any Royal device, or any arms or device closely resembling them, any title containing the word "Royal," or any name suggesting the patronage of the King or any member of the Royal Family, or connection with the Government, unless they were in use on April 10 last.

News and Notes.

TYNESIDE PHOTOGRAPHIC SOCIETY.—This society has changd its name to the "Newcastle and Tyneside Photographic Society" since its headquarters are in Newcastle.

THE BIGGEST AUSTRALIAN PHOTOGRAPHIC SOCIETY.—We learn from the Australian papers to hand this week that the Melbourne (Victoria) Camera Club now has a membership of 200, making it the largest photographic society in Australasia.

"F. W. P.," BRIGHTON.—A customer of Messrs. Hood & Co., Ltd., having the initials we have quoted, and resident at Brighton, who recently sent a small remittance to Messrs. Hood, but without giving his address, is asked to write again, in order that his request may be complied with.

PLATINOTYPE PAPERS.—The Platinotype Co. announce a reduction in the prices of Platinotype and Palladiotype papers of about 12½ per cent., which they have been enabled to make in part as a result of some reduction in the price of platinum metal, although the latter still remains at an exceedingly high level.

PICTORIAL PHOTOGRAPHY IN AMERICA.—The annual publication issued under this title as a selective record of the harvest of pictorial photography in the United States is announced to appear in October next. The selecting committee consists of Dr. A. V. Chaffee, Mr. John Paul Edwards, Dr. Arnold Genthe, Mrs. Gertrude Kasebier, and Mr. O. C. Reiter. From the circular which has been sent to us it would appear that the volume will be published by Mr. J. D. Drew, 63, Cliff Street, New York.

THE CITY SALE AND EXCHANGE sends us from its branch 90-94, Fleet Street, a bulky list running to 144 pages of all descriptions of second-hand apparatus, including folding cameras of all descriptions. The catalogue contains particulars of some of the firm's own specialties in the way of new apparatus, such as the Salex vest pocket focal plane camera and the Salex reflex camera, the latter an instrument which is supplied in 3½ × 2½ size, complete with *f*/4.5 lens, for £10 17s. 6d.

THE CHOICE OF A LENS.—Messrs. Ross, Ltd., have just issued an illustrated booklet containing hints and suggestions on the choice of a lens, in the text of which will be found much information written in non-technical language and conveying advice on the most advisable choice of a lens for different branches of work. The booklet includes particulars and prices of the Ross objectives of various types, and is obtainable free on application to 3, North Side, Clapham Common, London, S.W.4.

MESSRS. DALLMEYER'S NEW CATALOGUE of their well-known lenses is a handsome production which will perhaps invite perusal as much for the reductions in prices of many instruments as for the excellence of the printing. A feature of the list is the full particulars given of the many series of lenses and of the cameras of repute which can be supplied fitted with one or another of the Dallmeyer objectives. The list is obtainable free from Carlton House, 11d, Regent Street, Piccadilly Circus, London, S.W.1.

PHOTOGRAPHS NOT EVIDENCE.—During the hearing of a bigamy charge at the West London police-court last Saturday, evidence was being given by one of the secretaries of the Marriage Department at the town hall in Paris, when the prosecution sought to prove publication of the notice of intention to marry by producing a photograph of a notice stated to have been posted up at the town hall. The accused's counsel objected to this, as being unauthorised and secondary evidence. The magistrate upheld the objection, and excluded the question of publication of the notice. It was stated that the French authorities would not allow the original notice to leave the country; hence a photograph of it.

MESSRS. ROBBINS, MANISTRE (The London Camera Exchange), 2, Poultry, Cheapside, London, E.C.2, send us a copy of their 60-page list, just issued, of second-hand apparatus, offered at prices which represent systematic marking down in accordance with the reductions now taking place in the apparatus trade. The list includes an immense variety of folding pocket, reflex, Press, and other cameras, and has a particularly large section itemising the field, stand, and studio cameras of interest to professionals. Lenses also occupy a number of pages, so that portrait photographers revising or adding to their equipment are offered a favourable opportunity of doing so by paying a visit to this leading firm whilst in London next week for the Fair.

SOLDERING ALUMINIUM.—The following method has proved very satisfactory and far superior to and more lasting than any previously tried. Use a pure aluminium soldering "iron," which can readily be made from a piece of ⅝ in. or ¾ in. round or square aluminium; tin the parts to be soldered wth a composition of 81 per cent. tin, 16 per cent. aluminium, and 3 per cent. of copper. This is not a new composition, but in the proper method of preparing lies the success. After fusing the copper, add the aluminium a little at a time while constantly stirring with a piece of iron; then add the tin, and also a small portion of tallow; after the ingredients have all been added, care should be taken not to overheat.—"Amer. Machinist," through "Chem. Trade Journ.," March 31, 1922, 398.

OSRAM DAYLIGHT LAMPS.—A recent new introduction of the General Electric Co. is a metallic filament lamp in a blue bulb, the light from which approximates very closely to daylight in its spectral composition. The lamp is finding applications for many purposes where exact matching of colours by artificial light is of importance, as, for example, in drapers' shops, colour-printing factories and in museums and art galleries. It can be readily assumed that the lamps will be found useful in photographic workrooms, where the toning of print-out or development prints has to be done by artificial light. With P.O.P., particularly, it is by no means the easiest matter to judge correctly of the progress of toning except by examining the prints for a moment in daylight. Particulars of the lamps are given in a circular, No. O.S. 2706, now obtainable from the General Electric Co., Magnet House, Kingsway, London, W.C.2.

PHOTOGRAPHS USED FOR SMUGGLING.—In an "Evening News" special article on cocaine smuggling it is stated that "a man in Manchester was suspected of receiving cocaine. All kinds of traps were unsuccessful, and for months the detectives could not discover his source of supply. Then they noticed that a number of photographs, but only one at a time, reached him through the post. They were enclosed in envelopes marked 'Photograph only,' and the flap was left open for inspection by the postal authorities. Ostensibly to protect the photograph two pieces of cardboard were inserted in the envelope, an elastic band covering the whole contents. Between the two layers of cardboard was a thin sheet of tissue paper, and there was a similar sheet between the cardboard and the photograph. The cocaine was very carefully dusted over the tissue paper, and to the astonishment of the authorities a remarkable quantity was conveyed in the one envelope."

Correspondence.

CONVECTION CURRENTS.

To the Editors.

Gentlemen,—The words "either one strip immediately above another, or," in the second paragraph of column II. of the communication "On Convection Effect in Photographic Bathing Operations in the Absence of Agitation," on p. 110 of the February 24 number of your journal should have been either qualified or deleted. That this was not done is due to an oversight on the part of the writer when gathering the established facts from his note-book, and endeavouring to describe them as concisely as possible. The full sentence reads: "If two or more strips of film are arranged in a long tube, either one strip immediately above another, or with intervals between each strip, and bleached simultaneously, each strip shows the effect independently of its position, and in a degree varying only with its length."

Tests had, indeed, been made, when testing the effect of hydrostatic pressure with strips of film immediately above one another, but in vertical planes alternately at right angles, and under these conditions it appeared that each strip showed the effect approximately independently of its position, and in a degree varying only with its length. Somewhat later tests in which the strips were in

the same vertical plane, but separated by intervals of one picture height (¾ inch) or more, gave the same result; and the two sets of facts were then incompletely and, therefore, inaccurately described together in one sentence.

In your comment on this, in the second paragraph in column II., on page 107, you remark that "one would naturally have expected that the exhausted stream from one strip would have affected the rate of bleaching on the next strip." Further tests, using strips of cinematograph film with identical developed images—a "stationary movie"—and ferricyanide-iodide bleach as before, show beyond doubt that two strips carefully arranged immediately above each other in the same vertical plane bleach *as one*. Nevertheless, with an interval equal to the height of one picture, the original observation of approximate independence of effect is confirmed; and, what is somewhat surprising, the interval may be reduced to 5 millimetres with no marked difference in the result, although the vertical convection current can be seen rising without perceptible deviation and striking the lower edge of the upper film. A still further reduction of the interval gives effects *intermediate* between approximate independence and an action as one unit. With a break of 5 millimetres or more, it may be surmised that the depleted concentration of iodide ion in the liquid of the upward current is largely restored by diffusion before the upper strip is reached, although the current still continues (under its own momentum).

The word "independently" should not in strictness have been used without qualification, for density measurements show that the action on the upper strip as a whole is (slightly) slower than that on the lower strip. Qualitatively, however, the effect is the same, namely, a continuous, but not uniform, diminution of density of residual silver on partially bleaching (and fixing) from the top to the bottom of each strip, the density changing faster near either end than near the centre.—Very truly yours,

E. R. Bullock.

Research Laboratory, Kodak Park, Rochester, April 14.

PORTRAITS AND THEATROGRAMS.

To the Editors.

Gentlemen,—With reference to your reports of recent lectures by Dr. Goodwin and Mr. Lambert, and the letter from Mrs. Maud Basil in your issue of the 21st inst., will you allow me to express a very hearty agreement with most of the contentions of the former gentlemen, more particularly with Dr. Goodwin's denunciation of what he justly called "adulterated portraiture," of which, with its "fancy lighting, stagey posing, and loud backgrounds," we are seeing a good deal too much of late! Further, though without any intention of being ungallant to a clever lady, much of whose work I have often admired, may I say that her letter does not appear to do much to disprove the opinions of Dr. Goodwin, while, at the same time, she contradicts herself by saying in one place that "portraits and theatrograms are not the same thing," and in another that the "best portraits are also theatrograms," two statements which the mere male mind is not able to reconcile.

I am especially moved just now to support both Dr. Goodwin and Mr. Lambert because I have recently become aware of a certain propaganda to popularise what is known as "spot lighting," with all its accompanying eccentricities and unnatural vagaries, ostensibly with the idea of creating a fresh vogue and of stimulating public interest in the at present rather moribund business of portrait photography. This it might possibly do, but only among unthinking and inartistic people, and only then for a very short time, and the new fashion would soon go the same way that, as I am glad to observe, the so-called "sketch" work is going, and that is out of favour among the better class of clients. Besides, just anybody would quickly learn to "play about" with a spot light, just as everybody quickly learned to do "sketch" work, whereas what every photographer should do to improve his business is to try to produce something absolutely personal, and which cannot be got just "round the corner."

The way to do this is to study Nature and human nature, and the powers and limitations of the process; and to do this from the solidly sane, natural, and serious standpoint, as was done by the new "old-fashioned" (from the modern art student's point of view) Old Masters, and by such photographers as D. O. Hill at the one end and Furley Lewis at the other of photographic practice.

Their plain, simple methods of posing and lighting would, I think, do more to "emphasise the personality of the sitter," which Mrs. Basil rightly regards as of so much importance, and, incidentally, to improve business among educated and worth-while clients, than any amount of "spot lighting" and other theatrical devices, in which the art (or artfulness) is not of the type "eclare artem."—I am, Yours faithfully,

Drinkwater Butt, F.R.P.S.

2, Margravine Studios, Baron's Court, W.6.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—In reply to Messrs. W. J. Smith and E. L. Turner I am afraid that they have misread the passage referring to the change of stops. What I said was that the screen distances advocated by them would not produce satisfactory negatives with the same stop and exposure with different screen rulings. This is strictly true when one stop only is used for the exposure, and is the basis of my argument.

If at Bolt Court they teach a system based upon the use of more than one stop then it may be possible to use the same stops with different rulings, but the proportion of exposure with each stop of the series will vary with each ruling, which is much the same thing in principle, and makes exposure a variable when it should be a constant.

With regard to the so-called "pin-hole theory," it was perhaps not quite the best term to use, but it is one which I have heard so frequently when discussing some of these problems with operators that it came naturally. What I had chiefly in mind were the writings of some of the early investigators, such as U. Ray, Max Levy, and others in "The Process Year Book" in the late eighteen hundreds, about the time that the normal distance equation was evolved, and particularly an article by U. Ray in 1898, page 37, where he showed diagrammatically that the enlargement of a stop would actually decrease the nucleus of the dot from the fact that the screen focus had been upset. Many operators to-day believe in focussing the screen for each change of extension and stop.

Personally I do not agree with U. Ray's conclusions, and I only introduced the subject to try and arouse discussion. I see no reason why the stop should not vary from the usual equation if it is varied with a definite object in view. What I find fault with is the use of several stops in the making of a negative, when, in my opinion, a single stop will do the work as well, or better.

I am pleased to see that Mr. Hislop has written on the subject, and that he is in practical agreement with me on most points. He has fallen into the same error as Messrs. Smith and Turner with regard to the change of stop. My remarks about the necessity of using *f*/64 with a 200-line screen to obtain the same effect as *f*/32 with a 50-line screen were intended as an illustration of what undoubtedly is necessary when one stop only is used. The same gradation can be obtained with the same stop and exposure with both screens, but not with the screen distances as advocated by them.

I am satisfied that diffraction is the deciding factor in locating screen distances by calculation, and although I agree with Mr. Hislop that every screen has its own individuality, when the diffraction fringe has been measured and allowed for in the calculation the screen distance so found is so near that very little final adjustment is necessary. My investigations are not yet completed, but I shall probably publish some diffraction photographs shortly to prove my contentions, and then Mr. Hislop will, I hope, agree that no very great accuracy is needed to be able to measure the phenomenon and profit by it in every-day practice. As far as I have gone at the moment I can state the following:—

1. That the diffraction is strictly in proportion to the screen ruling.

2. That the diffraction is in inverse proportion to the diameter of the stop.

There, for the present, I would like to let the matter rest until I hear if anyone else has anything to say about it, especially as I purposely raised several controversial points in my article.

E. A. Bierman, F.R.P.S.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 3-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. V.—We suppose you refer to film title negatives. You can get these from Mr. A. W. Bowen, 26, Dartmouth Park Road, London, N.W.

J. A. F.—Plaster busts to serve as models for studies in lighting may be bought from Messrs. D. Brucciani and Co., 254, Goswell Road, London, E.C.1.

H. and D.—The collected researches of Hurter and Driffield, edited by Mr. W. B. Ferguson, are published by the Royal Photographic Society, 35, Russell Square, London, W.C.1.

L. E. T.—The Society of Radiographers has its headquarters at the Electrical Department, Cancer Hospital, Fulham Road, London, S.W.6. Particulars from the Secretary, Mr. George F. Westlake, at this address.

T. F. E.—Two firms of printers of stylish letter headings suitable for use by photographic studios are Messrs. Hood, Ltd., Sanbride Works, Middlesbrough, and Messrs. Walter Pearce and Co., St. George's Press, Brentford.

F. M. C.—From the greenish tint of the image in the negative we should say that it has been developed with pyro-metol, formula for which you will find in the "Almanac," and in the instructions issued for their plates by the Imperial Dry Plate Co.

INVENTION.—If you know the name of the patentee, you can find any given specification of his which has been published by reference to the annual indexes of patentees which are kept in the Library of the Patent Office, 25, Southampton Buildings, London, W.C.2.

T. F.—The address of the Registrar of Business Names is now 4, Clement's Inn, London, W.C.2. Form for registration of your business is obtainable from him. As you do not trade under your own name, you are required by the Business Names Act to register. The Act applies both to British subjects and to aliens.

C. C. E.—There is no really satisfactory method of reducing the depth of sulphide-toned prints which are too dark. Most sulphide-toned prints become lighter on immersion in a weak solution of potass cyanide, but the action is somewhat erratic, and this treatment is pretty certain to affect both the colour and the gradation of the print prejudicially.

R. E.—There is nothing in the fact of enlargement by daylight to account for the failure in subsequent sulphide toning. We think the cause is to be sought in the method of development. Possibly your daylight exposure received less development, and so caused an inferior result in the sulphide toner, although not showing perceptible inferiority as a black-and-white print.

EURYSCOPE.—We are quite sure you will regret going to the expense of fitting a heavy rear extension to your light model half-plate camera. The latter is not strong enough for the purpose. Far better buy an old pattern square bellows camera of sufficient extension. You can get cameras of this kind second-hand at prices which probably will be less than the amount which your suggested extension will cost you.

Q. Q.—Trade lantern-slide colourists chiefly use oil colours. The technique of using oil colours requires some practice, especially as regards getting an even tint in skies and similar parts. If you write to Messrs. Winsor and Newton, 37-38, Rathbone Place, London, W.1, they will send you a reprint of an article which we published last year, giving very good working instructions in the use of oil colours for lantern slides.

J. B. A.—There is nothing in the particulars which you give of your manipulation of P.O.P., bromide and self-toning papers to account for the fading. The manipulation is quite correct, and shows you to be exercising more care in the operations than is often given. If you were to send a few unmounted specimens of prints which have faded, we could perhaps give some indication of the cause, although it is by no means easy to do so.

T. B. M.—No, it is scarcely correct to say that the depth of focus of one 6-inch *f* 6 lens is exactly the same as that given by any other lens of the same focal length and relative aperture. Such would be so only if all lenses were identical as regards the flatness of field. But since the field of sharp definition given by some lenses is distinctly curved, subjects may frequently be encountered with which this defect is a substantial advantage as regards getting near and distant objects in focus with a comparatively large aperture.

21—X.—We are afraid you are letting yourself in for a much longer job than you realise. Of late years there have been hosts of patents for cinematograph shutters, in many of which avoidance of flicker is claimed as a feature. The only thing you can do is to look through these specifications in the Library of the Patent Office, 25, Southampton Buildings, London, W.C.2. The classified abridgments of specifications, published by the Patent Office, will give you a pretty reliable key to the numbers of specifications to be examined.

F. J. C.—Sulphide toning is a very satisfactory method of making sepia-toned lantern slides, provided the black-developed slides tone readily. Some brands of lantern plate yield slides which tone most satisfactorily by this method, while others that we have met with bleach out, but do not come up fully again in the sulphide solution. The process gives slides of great transparency in the shadows. In this respect it is inferior to the results obtained by copper toning, although the latter is a process which works without exception on any make of lantern plate.

H. J.—The "B.J." pyro-soda developer can be used as a tank developer, although as it is a rather slow-acting formula, it is, we think, not altogether the best for tank work, and we would just as soon use a formula of the ordinary type, especially where the developer will be thrown away after it has been used for a batch of plates. It is usually advisable to employ a 5 per cent. sulphite solution for dilution of the developer in place of, say, half the water, when diluting an ordinary formula for use in a tank, but the "B.J." formula is so free from stain that if you do use it we do not think extra sulphite is necessary. The only time and temperature tables which have been published are those contained in an article in our issue of July 9, 1915, p. 445, in which dilutions and times were given in accordance with the Watkins' classification of plates as regards speed of development. We think you could develop a second batch, although in these circumstances you could not expect to repeat a given time of development at a given temperature. As good a formula for the acid fixing bath as any that we know is the ordinary 5 ozs. hypo in 20 ozs. water, with the addition of about ½ oz. of potass meta-bisulphite.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3235. Vol. LXIX. FRIDAY, MAY 5, 1922. Price Fourpence.

Contents.

SUMMARY.

In the second of the series of chapters on the business side of professional photography, "Pelham Swinton" has many shrewd observations to make on the relation of the photographer to his customer, and inquires particularly into the average customer's state of mind regarding the artistic quality of portrait photographs. (P. 263.)

A contributor to one of the electrical journals expresses the opinion that photographers are justly entitled to the power rate for current used for studio lamps, etc. (P. 266.)

The thirty-guinea cup offered by Mr. Arthur Brookes for the best exhibit of American portraiture at the Photographic Fair has been awarded by Mr. William Crooke to Mr. F. A. Free, of Davenport, Iowa. (P. 267.)

To sue a customer for the cost of a sitting, the results from which fail to satisfy, not only raises a legal issue of much doubt, but involves the risk of a very bad advertisement for the photographer. (P. 261.)

In a leading article we review some of the practical methods which can be adopted in making presentable enlargements from negatives which may suffer from excessive hardness and from coarse-grained originals, even prints from half tone blocks. (P. 262.)

A committee has been appointed under the Safeguarding of Industries Act to hear "complaints" regarding the sale of optical and other instruments manufactured in Germany. The committee will hold its first sitting on Monday, May 15. (P. 270.)

The third Hurter and Driffield memorial lecture will be delivered next week by Professor Svedberg. This meeting will be held at the Royal Society of Arts, and will begin at 8 o'clock. (P. 267.)

Photography with a hand camera is now permitted in the Royal parks without a permit. (P. 269.)

Processes for obtaining distinctive effects by transfer of a development print are described in a recent patent specification. (P. 266.)

A mixture of two desensitising dyes has been worked out by Dr. König, and is said to be free from the defects of phenosafranine while equally efficient as a desensitiser. (P. 262.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In an article on some causes of failure in Autochrome work, Mr. R. M. Fanstone emphasises the importance of bright lighting at the time of making the exposure, and also of several details in the development and after-treatment of the plates. (P. 17.)

The conclusion of the illustrated chronology of the Photochromoscope, by E. J. Wall, will be found on page 18.

M. A. Keller-Dorian has patented the use of a reflector in the refraction colour screen-plate process. (P. 20.)

A new edition of Dr. Lindsay Johnson's "Photography in Colours" is announced. (P. 20.)

EX CATHEDRA.

The Unsatisfied Sitter.

We are sometimes asked whether a customer can legally claim the return of any money paid at the time of the sitting, if he, or she, is not satisfied with the proofs and cannot, or will not, give another sitting. Any dispute of this kind, if taken into a County Court, would turn upon the particular circumstances of the case and also, very largely, upon the personal opinion of the judge on the point of whether the photograph was, or was not, a satisfactory likeness. We would never for an instant recommend a photographer to be led into such proceedings as these. Legally the issue is doubtful in the highest degree; it would serve just as useful a purpose to agree with the sitter to decide the dispute by tossing a halfpenny. But apart from this it is a very poor policy to confess an inability to do what the customer wants. If his, or her, requirements appear to be unreasonable, and if there is a flat refusal to visit the studio for another sitting, by far the best course is to return the money with regret that an opportunity is not available for making further negatives. The customer must then be left with the impression that the photographer is, at least, a fair and obliging person, and if she is no more fortunate elsewhere may return to him in the end. In the alternative the result may be that reported County Court proceedings may advertise the photographer as both inefficient and unreasonable.

* * *

The Sitter's Permission.

As a correspondent points out in references to our paragraph of last week on "Speculative Portraits," a photographer is not within his legal right in commissioning the making of an enlargement in colours from the negative which he has taken of a sitter nor in showing the enlargement in his window. Nevertheless, we do not think that the legal disability need deter anyone from acting upon the suggestion which we made. For, as a matter of fact, it is surely generally recognised that this right of the sitter is very seldom exercised, and is more honoured in the breach than in the observance. In ninety-nine cases out of a hundred a sitter has no objection to her portrait being shown in a photographer's window, but, on the contrary, is secretly flattered by its selection for this purpose. Occasions may arise in transactions with normal people when the request is made for a portrait to be removed from exhibition in this way, and to that request, of course, a photographer has no option but to comply. Therefore, despite our correspondent's objection, we think that opposition to the showing of a more elaborate or ornate portrait than that which the sitter ordered is likely to be very seldom made. The photographer's choice of a subject will indeed be taken as a special compliment, and will smooth the way for sale of the enlarged portrait to Mrs. A, or of others like it to Mrs. B, C, or D.

Pinakryptol Desensitiser. In an article which appears in the current issue of "Photographische Rundschau," Dr. E. König, of the Hoechst firm of Meister, Lucius and Brüning, has an article which gives a general outline of further experiments which he has been making on dyes which act as desensitisers of photographic emulsions. Dr. König was associated with Dr. Lüppo-Cramer in the latter's work on this subject, and has now completed a lengthy series of experiments which, it is stated, have led to a desensitiser fully equal in its effects to phenosafranine, but without some of the drawbacks of this latter. The name "Pinakryptol" is applied to this preparation, which is a mixture of two desensitising substances, forming a greenish-grey powder. It is used in the same dilution as phenosafranine, namely, 1 part in 5,000 parts of water, and has the advantage of being free from any staining action on fingers or nails or the gelatine or celluloid of photographic materials. Dr. König expresses himself satisfied that the advantages of the new preparation are such that it will immediately displace phenosafranine as a desensitiser.

SOFTENING ENLARGEMENTS.

THERE are many negatives which, from a variety of causes, are incapable of yielding good results if enlarged from in a straightforward way which would answer well with a good negative, and it may be well at the outset to define clearly between the two main classes which necessitate softening methods. In one may be placed those negatives which although satisfactory in other respects are very harsh in their contrasts, leaving the operator to choose between "soot and whitewash," the result of a normal exposure or the poor rusty colour which comes from the long exposure necessary to penetrate the high-lights. In the other class may be placed those which by reason of great enlargement from a granular image, or by being copied from bad originals, need the grain to be rendered less obtrusive than it would be in a "straight" print. In a few cases both these conditions may be present in one subject.

The methods to be adopted to remedy these defects vary considerably in their character, and cannot be appropriated entirely to either class of negative, several being of all-round efficacy. The most obvious course in dealing with a negative whose only fault is harshness is to use a paper with a long scale of tones, that is to say, one which will allow detail in the lights to be developed out without burying shadow details, at the same time preserving a good colour. Such papers are usually listed as "soft," and contrary to what might be imagined are not always rapid in working. Many of the newer brands, designed primarily for giving warm tones, are excellent for the purpose. It must be borne in mind that a strong illuminant is necessary with such papers, as a weak one, such as an oil light, would not penetrate the most opaque parts with any length of exposure, especially if the negative were at all yellow in colour.

Another method of reducing contrast is by breaking up the image into more or less distinct dots by means of a lined screen. This method was originated some years ago by Mr. Howard Farmer, who used a photographic copy of a cross-lined process screen. This was placed in contact with the bromide paper during exposure, which was five or six times as long as would be necessary with a normal negative. The action of the screen was to introduce a certain amount of white into the deepest shadows, thereby lightening them; although the same amount of white was present throughout the whole subject it was less apparent in the lighter parts. From considerable experience with such a screen, we are able to assert that the results so obtained are remarkably good. The only weak point about this method is that the necessary screens cannot be produced at a sufficiently low price to render them available for general use.

Failing such a screen, a piece of fine bolting silk, stretched upon a sheet of clear glass, forms a substitute which is by no means to be despised. This acts in the same way, but not quite to the same extent. If the bolting silk is in contact with the paper the grain is sharply defined, while, if the glass side is in contact, the grain is softened and the reduction of contrast is rather less. If the entire screen is removed farther from the paper, a somewhat different action is set up. Instead of breaking up the image, a diffusing action which scatters some of the light over the shadows is produced, the general definition being affected.

Coming to the other class of negatives, in which the granularity of the image is the trouble, the foregoing expedients may be used, or others less expensive may be adopted. A small lined screen fitted as a cap to the enlarging lens gives an agreeable amount of softening, enough to obliterate small freckles, retouching marks, scratches and similar defects, as well as reducing the coarse texture of copy negatives. With this, the degree of diffusion varies with the size of the grain of the screen, a fine screen giving the maximum of diffusion. In this position the action of the screen is quite different, the softening effect being due to diffraction. Instead of the lined screen, many workers use a piece of fine silk chiffon, which is stretched tightly over the lens and secured with a rubber band. Two or more thicknesses may be used if greater diffusion be desired. When using the cap-screen or chiffon, the image should first be focussed before screening the lens. The increase of exposure necessary is slight, compared with the screen in contact with the paper, from twenty to one hundred per cent. being the usual limits.

Various optical methods for reducing granularity have been proposed, and in some cases are satisfactory. When using a flat field lens, the image may be put slightly out of focus or, what is better, a lens with a soft focus adjustment, such as exists in the Dallmeyer, Cooke, and Aldis lenses, may be used. This, however, cannot be done to any great extent, as the halo thus produced spreads *inwards* round the shadows, and the effect is far from pleasing. An ordinary single landscape lens used at an aperture of about *f*/8 may be used as the enlarging objective with good effect; in fact, such lenses were used in the old days to subdue the brush markings on hand-painted lantern slides, before photography was generally utilised for lantern slide making.

As an example of a difficult problem in softening the image the following may be interesting. A 15 × 12 enlargement had to be made from a one-inch head, the only available original being a coarse half-tone print cut from a daily paper. This was copied, full size, in the ordinary way. The image was projected by means of a Cooke lens and focussed so that the edges of the screen image were slightly softened. The Farmer grader was placed in contact with the paper and the exposure made with the result that the image appeared like a fine-grained process block, the large grain being so broken up as to be practically invisible. When finished, there was no trace of the origin of the picture. It is seldom that such a problem presents itself, but there are many lesser ones, such as the practical worker encounters every day, when the adoption of one of the hints we have given will reduce the labour of finishing by fifty to seventy-five per cent., besides greatly reducing the risk of losing the likeness.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

[In this second of a series of papers by a professional photographer of note, the author, writing over a *nom de plume*, examines with much insight and a good deal of humour the relation in which a photographer peculiarly stands towards his client or customer. He is under no illusions as to the appreciation of "art" by the public, and his healthy cynicism in this respect, however unpalatable to those who interpret generous patronage as a kind of certificate that their works are "art," may be recommended as sound guidance in the business of selling portraits to people whose standard of art is something very different from that of an artist's.]

II. THE PHOTOGRAPHER AND HIS CLIENT.

I have used the word "client" with diffidence owing to the fact that, in a recent court case, the judge is said to have registered his objection to the use of the term by other than professional gentlemen; and it has not yet been definitely decided whether we are really professional gentlemen or merely commercial persons with no hope of heaven at all. It will be remembered that a test-case arose during the war, when a well-known photographer applied for exemption from payment of excess-profits duty on the ground that he was a professional man. The court, however, made the startling discovery that the applicant was not a man, but a limited company, and the case was dismissed. The inference which we may draw from this decision, therefore, is, that when a man wishes to limit himself, and goes through the somewhat expensive ceremony of registering his name at Somerset House, he surrenders all claim to individuality, and that, logically, he should, like the professional cricketer, forfeit his right to be a Christian, and be known only by his last name.

Yet, how can a man enter the hereafter as a limited company? These intricate metaphysical questions are a source of considerable worry to the professional photographer, and it is a pity that the legal intellect has not favoured the world with an opinion on the subject—if a hereafter is recognised by a court of law.

To descend, however, to the practical, the photographer's client, or customer, is—or should be—his first object of study. A man may possess a deep insight into chemistry, understand all knowledge and all mysteries concerning optics, and have sufficient Art so that he could remove mountains, yet if he understand not his customer he is as sounding brass or a tinkling cymbal, and his balance-sheet will show a deficit at the end of the year.

This understanding of his customer is one of the factors of his business which has been most consistently neglected by the professional photographer. The grocer and the draper have brought this subject to the level of a science; yet the photographer has contented himself with immersion in such things as Art, the latent image, and the anastigmatic lens. Art is the prerogative of the academician and the amateur, while the other subjects are surely the concern of the apparatus and material manufacturers. The business of the professional photographer is to produce photographs for the public, and to discover what kind of photographs is best calculated to please the majority of those people with whom he wishes to deal. He should, therefore, cease his endeavour to study other people's businesses, and turn his attention to the direction of his own. It is, fortunately, a much more simple undertaking. It is not suggested that he should be entirely ignorant of such matters; but it is suggested that this aspect of professional photography is pre-eminently the most important.

Many photographers fail to realise that they are in business primarily for the purpose of making a living, and that this can be done only by selling their product to the people who pass by. These people in the street may be good citizens—and even Christians—but they will certainly not stop on their way to drop a guinea or two into the photographer's cash-drawer merely because the poor but honest gentleman is under the necessity, like the rest of the world, of paying his tradesmen's bills. They know quite well that the photographer must live—but so also must they; and if the photographer in question has an old-fashioned show-case and insanitary specimens, they presume that he is doing well enough, and that he has no need to bestir himself like other people. Certainly there is nothing in his specimen display calculated to induce anyone to patronise him for other than charitable reasons.

Meanwhile, our photographer sits in his studio, hating the people who pass by, and wondering why they do it. "Things weren't like this in the old days," he says. Those were the days, probably, when his specimens were new. "The public doesn't seem to appreciate good work as they used to do," he concludes. And he drowns his sorrows in the problems of diffused focus.

If the photographer wishes to earn a livelihood, he must, by means of his show-cases and other forms of advertising, create the desire for possession in the minds of the passers-by. It has already been pointed out that a photograph is a luxury. Except in a time of war, there is absolutely no necessity for anyone to be photographed. A woman will go out of her way to buy bread because she needs it in order to live; but she will not think of having a photograph taken unless she sees one which is displayed in a manner sufficiently attractive to create in her mind first the suggestion and then the desire.

But here we come to the next point. Suppose that the photographer's show-cases are clean, his specimens new, and his doorway not unattractive. He has arranged his display with care; and he bethinks himself fondly of the fine compositions, the correct tone-values, and all the subtle lightings, exemplified in the various prints. Yet his specimens still remain unadmired by the passing crowd. What can he do now? Surely here is proof of the public apathy toward Art! It is. And it is also convincing proof of the photographer's lack of appreciation of the public. He has thought of nothing but his lighting and his composition, and has forgotten entirely the fact that his object is to sell his portraits to the people outside, and not to himself. He is fully aware of the qualities which he admires in a photograph, but he has never exercised his imagination to discover what the public may prefer. This lethargic attitude is based on the fallacy that the general public is artistic. It is not. It is only necessary to look at the things which it hangs on the walls of its homes to realise this fact in its most awful form. And the shocking truth of the whole matter is that these people rarely notice lighting, do not care twopence for composition, and have not the slightest idea what tone-values are.

This lack of appreciation of the fact that the public may hold a different opinion as to the merits of a photograph is the chief cause of non-success in a photographic business. I do not suggest that the public is right in its opinions; on the contrary, it is nearly always wrong from the aesthetic or artistic point of view. But here is the crux of the matter. The man or woman purchasing a photograph does not want Art. What he or she desires primarily is likeness. So long as the Art does not interfere with the likeness, no objection will be made, and the photographer may amuse himself in this way if he care; but when the pictorial properties of the photograph commence to subordinate the likeness, then friction

arises. The reason of this is obvious. When people wish to decorate their rooms they buy oils, water-colours, or etchings. In their choice of these they may allow free play to their personal taste; or, if they are wise, they purchase works by only expensive artists, and their taste is established beyond doubt. But when the same people require a photograph it is rarely for decorative purposes, but usually in order to record the likeness of someone at a particular age, or in a particular dress. Hence the æsthetic in a photograph is not sought for, and is, at best, of purely secondary consideration.

It may be taken that only about one person out of every five hundred customers of a normal high-class studio will object to a photograph being poor in quality, or badly composed; while only one individual out of five thousand who patronise such a studio will so much as understand a portrait in an oil process. Thus, if a photographer sets out to do only that kind of work which is most pleasing to his own taste, and that taste is a high one, he will require a potential *clientele* as large as London in order to live comfortably.

Yet, in spite of all these facts, it is found that when a photographer has his portraiture praised by a customer he says to himself: "That client, at any rate, appreciates my artistic endeavour." And he looks with pride upon the long scale of gradation, the transparent shadows, and the sparkling high-lights (complete as advertised by the material manufacturers). He would feel somewhat pained, however, if he could know what that customer really admires in the photograph. If it is not merely the likeness which has evoked the expression of pleasure, it will be the effect of some hard outline or insufficiency of half-tone which has unwittingly crept into the picture, and of which the photographer is secretly ashamed.

When, on the other hand, a client violently condemns a portrait—apart from the likeness—it is because he has stumbled upon the results of the "artistic endeavour" just mentioned, and objects to it very strongly. Then the photographer says to himself: "This person has evidently no appreciation of tone or quality or composition. How can I make him see what I see, so that he may realise all that I have put into this portrait?" And he concludes: "I must educate him"—forgetting the millions of pounds spent on education by the Government every year with so little result.

In order to gain fuller experience in the business side of photography, I spent some time acting as receptionist for my own firm. A male receptionist is an unusual thing, but the public did not seem to show surprise. During part of my tenure of this important office there hung in the reception room, in a prominent place, a picture of which we were rather proud. It was an oil print, one of the best we had produced, and in its year had been hung in the Royal Society's exhibition. It had occasioned some notice at the time, and had been described by the art critics as "a noble work in oil."

None of our customers, however, seemed to pay any attention to this picture; and I commenced to wonder why "a noble work in oil" should cause so little comment. One day, however, I learned the reason. A lady, while waiting for her son to arrange an appointment, caught sight of this masterpiece, and, raising her lorgnettes, she exclaimed to the young man: "Or, *do* come heah! Isn't this keoice! So doke." Which is to say, being interpreted, "Isn't this curious! So dark!"

They examined the portrait for a moment, and then went their way. For all its art and its nobility, to the passer-by it was but a freak—obviously a photograph which had been left too long in the sun, and had become badly over-printed. I thought of the puny opinions of the art critics, and bowed my head in silence before the verdict of the great British Public, by whom we eat, drink, and have our being. This portrait is now removed to a quiet corner, and a large vignette hangs in its place.

Conversely, photographs at the opposite end of the æsthetic scale I have found to be praised rapturously. Especially is this the case with studio photographs emanating from Australia. A few of these have percolated into our studio from time to time for the purpose of being framed, and invariably we have been told how beautifully Australian photographs "come out." "They are so clear," it is pointed out. "Of course, it is the atmosphere there, you know. *So* different from our own climate."

As far as one can judge from these examples, the secret of the Australian portrait is embodied in the fact that it is simply three times harder than anything anyone has dared to produce in this conservative country, and that the retouching is performed with an even greater obliviousness to anatomy than the wildest dreams of the Society photographer. And the public is delighted. Nevertheless, it will be noted, the poor Australian photographer receives no credit for his cleverness. It is the atmosphere.

Thus we may conclude that if the photographer wishes earnestly to do business, and not merely to conduct an expensive and cultured type of hobby, he must not only have an attractive means of displaying his work, but he must show that kind of work most pleasing to his class of customer. Let him forget about art, and the latent image, and the anastigmatic lens, and turn all his energies in the direction of creating desire for his photographs in the minds of the public. Let him ask his wife, or someone who knows nothing of art, to give him a frank criticism of his specimens, and let him encourage her to point out those prints which she finds appeal to her most. Provided her mind is quite untrammelled by a knowledge of either composition or quality, she will select rightly, and her opinion may safely be taken as the opinion of the crowds who pass by.

People who have no immediate intention of being photographed look at a photographer's show-case for two reasons: Firstly, in order to see if there is a portrait of anyone whom they know, and, secondly, in order to see if there are any "pretty photographs." A "pretty photograph" involves, primarily, good looks; secondly, an attractive dress (such as in the case of a bride); and, thirdly, any unusual manner of posing which may be employed. It will be noted that neither quality nor composition is necessary. Lighting, if very unusual, may have an effect on the spectator, and this, in most cases, will be a subconscious one. A bride is probably the most attractive specimen which can be placed in any show-case. It may be relied upon to possess a magnetic range of twenty yards.

Thus, attractiveness in a specimen has little to do with the skill of the photographer, save in the case of posing. Even this depends largely upon the sitter, because if she have not an elegant figure it will be difficult to make much of the portrait, so far as a specimen is concerned. All that the photographer can do, having secured a well-dressed and handsome sitter, is to make the most of the opportunity. And this is no great task. Well-dressed and handsome women are rarely difficult subjects; yet, for every graceful curve of the body, and each beautiful line of the nose and mouth, the photographer will receive credit. People do not stop to think how much is photographer and how much is sitter in a photograph. On the other hand, no matter how great his triumph in producing a pleasing photograph of an awkward, nervous, and not too handsome subject, he will get credit only from the sitter and those who know her. Let him never, in the pride of the moment, attempt to use such as a specimen. Strangers would glance at it, say, "I don't think much of *that* photograph, anyway," and pass on. He must be prepared to accept all blame for the physiological deficiencies of his clients.

The far-seeing photographer, therefore, will fill his show-cases with a series of beauteous damsels—preferably of slightly theatrical appearance—gazing upward (or downward) with an expression of what is presumably fashionable languidness, but which strongly suggests indigestion. These—the other

to his doorway, and some up to his reception room. Here a further array of similar ladies must be on view, and not inferior in beauty, languidness, etc., to those downstairs. On the fresh wave of admiration which these arouse, the prospective client should be washed into the studio. But here a different attitude must be adopted. We return to grim realities, and likeness is once more the predominant factor. However greatly a client may admire languidness and double-lighting in the portrait of a stranger, she will not allow them to interfere with the rendering of a recognisable likeness of herself. The photographer need have little fear of complaint being made at the omission of such things in the portrait. As soon as the proofs reach the sitter all thought of these things vanish. The beautiful damsels are quite forgotten, and an entirely new interest is aroused.

There are, of course, cases where likeness is not desired, and idealisation is frankly demanded. But such portraits are usually for the purpose of publication in the press; and there is no reason why truth should be told in the half-tone reproductions any more than in the text.

Next in importance to an alluring display of specimens comes the name of the photographer or his firm. If his name, as generously given him by his godfathers and godmothers in his baptism, be William Smith or Harry Jones, let him conceal the fact like a murder. More skill and art are expected—and discovered—in the creations of a foreigner than of anyone unfortunate enough to be British. In practice, however, it is not necessary that the aspiring photographer should be of French or Italian birth. All that is required of him is that he should assume a French or Italian name. Many far-sighted photographers in this country have already done this, and, unfortunately, most of the best names have already been used up.

The psychological reason for all this is to create an "atmosphere." It is no more possible to conduct a successful photographic business without an "atmosphere" than to produce a play without scenery or costume. While the vast majority of the public do not recognise an artistic photograph when they see one, it must not be supposed that they will pay three, four, or five guineas for photographs which they do not believe to be "artistic." It must never be forgotten that when a picture of any kind appeals to a middle- or upper-class person, he or she calls it "artistic." It is psychologically impossible for such a human being to imagine that anything which delights his eye can be otherwise. Hence, although Art in its true sense is not desired in a photograph, the purchaser will always endow with artistic qualities any portrait which pleases him. It may be because the likeness is good; it may be because the print is hard and clean; or it may be because the dress or suit is depicted in unexpected detail. The photographer, on the other hand, may wish that the print had been softer, or that the dress had been lower in tone, and he dispatches the order with feelings of misgiving. He is surprised to learn, however, a few days later, that his customer is delighted.

This atmosphere of "Art" must be maintained in the reception room and in the studio. The customer expects it; and to jar his susceptibilities by any suggestion of the truth is fatal. To prove that this is no idle cynicism I shall give an actual instance. A young woman entered our reception-room and asked to see the different styles. I showed her the various sizes, and told her the price of each. Having selected the size which she preferred, I pointed out that this could be obtained either with a dark background or with a light one finished in the sketch style, and I asked her which she would like. She said: "O, now which is the *newest?*" (She did not say "newer.") "The sketch is the latest and most artistic, isn't it?" I replied that the sketch style was by no means *new;* that our own firm had produced it continuously for the previous twelve years; and I added, by way of explanation, that there was really nothing new in photography; that one must have either a sketch portrait or a solid one, and that there was no escape from these alternatives. She made an appointment for the following day, and went out. She never came back. Had I told her a direct lie, and said, "O, yes, madam, this sketch style is the very latest thing in portraiture, and the most artistic style as yet reached by photography," she would have been delighted, and I should not have lost a customer.

PELHAM SWINTON.

(To be continued.)

FORTHCOMING EXHIBITIONS.

April 21 to May 11.—Hammersmith Hampshire House Photographic Society. Particulars from the Hon. Exhibition Secretary, J. Ainger Hall, 2b, Bishop's Mansions, Bishop's Park Road, London, S.W.6.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography." Open daily from 11 to 5 p.m. 35, Russell Square, London, W.C.1.

May 1 to 6.—Photographic Fair. Horticultural Hall, Westminster. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 18 to 22.

APPARATUS.—No. 11,175. Apparatus for coating photographic, etc., films. H. Lichte.

NEGATIVES.—No. 11,130. Negative registering devices. Offset Directoplate Co.

CINEMATOGRAPHY.—No. 10,909. Moving-picture cameras. G. W. Bingham.

CINEMATOGRAPH-PHONOGRAPH.—No. 11,019. Machines for synchronously reproducing sounds and projecting pictures. G. Bohn.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

REFRACTION COLOUR SCREEN-PLATES.—No. 153,151 (January 21, 1920). The invention consists in apparatus for a process of colour photography, and includes the combination with a sensitive plate (having microscopic refracting surfaces) and a camera lens, of a reflecting device. The latter has inclined surfaces, placed

between the lens and the plate, for the purpose of producing interference.—Albert Keller-Dorian, Rue Daguerre, Mulhouse, Alsace, France. (Details of the invention are given on another page in the "Colour Photography" Supplement.)

TRANSFER PRINTING PROCESSES.—No. 177,255 (December 22, 1920). A photographic print, produced upon a stripping substratum giving a matt or nearly matt surface to the face of the film, is transfered with the matt surface uppermost, to a mount between which and the picture film is produced a gelatinous transparent substratum of a reflecting or shiny character, the transfer being effected in such a manner as to make optical contact between the film and the said reflecting substratum.

The substratum may be produced by the aid of a gelatine adhesive layer so prepared as to give a sheen showing through the transferred emulsion. The effect of this shiny under surface is to increase the reflection of light through the parts of the print which are not too dense, and especially through the parts which represent high-lights, with the result that the lighter parts of the print are thrown into much greater relief than is the case with ordinary photographs, while the dark portions or shadows are intensified. In the complete print there are three surfaces of reflection, the upper surface, where the reflection is reduced by the matt effect, the paper or other mount, and the surface of contact or union between the back of the transferred film and the underlayer, which reflecting surface lies between the first two. The increase of reflecting power at this intervening surface in accordance with the invention gives the enhanced effect sought.

A convenient method which may be adopted in carrying out the invention is to coat the paper, card or other material with a solution of gelatine, a suitable strength being about 2½ per cent. of gelatine dissolved in hot water, applying the solution rapidly to the mount over a sufficiently large area to take the print and as evenly as possible, leaving considerably more gelatine than is required to make the photograph adhere. The card or paper mount is preferably previously damped or soaked for about a minute, or until it becomes limp, in cold water, laid on a flat surface and the surplus water removed with a sponge, whereupon the gelatine is applied, and the print is also damped or soaked and has its surplus water sponged from it.

The print may be prepared with a stripping substratum in accordance with the specification of Patent No. 164,448 ("B.J.," July 29, 1921, p. 452), but the present process is not confined to any special type of transfer print excepting that when transferred it must have a matt or nearly matt surface and be of such a nature that the light can readily pass through the lighter parts and be reflected by the backing, to give the required effect. The preparation of the print by the aid of the stripping substratum comprising an emulsion hardening agent as claimed in the patent above referred to, especially chrome alum, is a method particularly useful in conjunction with the present method of dealing with the transferred print.

The damp print is then placed face down on the mount, upon the coating of gelatine, the print being lowered gently down from one edge on to the gelatine surface, any air bubbles and surplus gelatine being squeezed out in the process of laying down and the surplus gelatine removed with a gelatine brush or a sponge. The mount surrounding the print is then sponged with clean water to remove any traces of gelatine.

Drying is effected by placing the mounted print in a current of warm air so that it dries fairly quickly, when dry the original support of the film being pulled away from the mount, leaving the picture on the mount with a shiny layer of gelatine beneath the film. The excess gelatine which is put on the mount is to minimise the risk of air bubbles getting in between the film and the mount, and avoids the necessity for heavily squeezing the transferred film, the method adopted giving a very even layer of gelatine.

In cold weather the damp mount can be laid on a warm surface such as a folded piece of fabric quickly removed from a dish of hot water, or the wet fabric may be laid on a warm surface such as glass, this keeping the mount sufficiently warm to prevent the gelatine from setting before the transfer is complete. When the print has been laid down, the mount can be removed to a cold surface such as a sheet of cold glass, quickly chilling the gelatine and allowing of sponging the mount without shifting the print.

The actual method of mounting can, of course, be varied, and a very satisfactory method in cold weather is to lay the damp mounting paper or card upon a piece of glass a little smaller than the card and just removed from warm or hot water before applying the gelatine; a soft gelatine is preferably employed, which may be put on with a brush or poured on the mount from a spouted jug, the warm glass providing sufficient heat to prevent the gelatine setting before the print is in position; the surplus gelatine can be poured into a jar and the margins of mount sponged with clean water to remove the traces of gelatine, after which the mounted print is removed from the glass and dried. By this method no gelatine is likely to get on the back of the mount. The best temperature of gelatine solution and water for warming the mounting glasses or fabric depends on the atmospheric temperature, as also does the temperature of the gelatine solution for mounting, such temperatures being readily determined by a little experience, as all that is required is enough heat to keep the gelatine solution in a sufficiently liquid condition till the print is properly laid down on the mount. Any other method of mounting which produces the underlying shiny layer may, however, be employed in the process.

The strength of gelatine solution can also be varied; generally from 2½ per cent. to 5 per cent. will be satisfactory; the warmer the weather the stronger the solution. For wood, glass, and such like surfaces a 5 per cent. solution will generally be found satisfactory.

No added pressure is put upon the print after it is laid upon the mount, merely the weight of the wet print being utilised; squeegeeing would squeeze out some of the gelatine and spoil the effect.

Most ordinary photographs on paper or card show a gloss or sheen more or less over the whole surface; in the case of certain papers, however, it has been found possible to eliminate the gloss and produce a matt or nearly matt surface without a glossy effect, but the result of this is often a loss of brilliancy. On the other hand, engravings on vellum or a similar surface appear much more brilliant than ordinary photographic prints owing to the contrast produced between the uninked surface and the matt or nearly matt surface of the ink, by the sheen of the vellum. The present process obtains an effect by purely photographic means which approaches that of an engraving printed on vellum or a similar surface.

The photographic transfer print may be prepared in accordance with the method described in specification No. 164,448 already mentioned. The method employed must not impair the ability of the film to transmit light readily through the parts which are not in deep shadow.—Frank William Kent, 5, Thornton Avenue, Streatham Hill, London, S.W.

The following complete specifications are open to public inspection before acceptance :—

APPARATUS.—No. 178,127. Photographing-apparatus. J. Pecsi.

APPARATUS.—No. 178,128. Apparatus for use in joining together lengths of photographic or cinematographic film. Correxmuvek Filmipari Gepgyar C. Lazzlo.

APPARATUS.—No. 178,430. Apparatus for direct vision or for projection of separate transparent photographic views upon films or the like. H. de Ruyter.

CURRENT AT POWER RATE.—In the issue of April 21, "Electricity," "Elektron" refers to the question of rates for electric current for photographic work. He says: "As an impartial observer I should say they (photographers) are justly entitled to the power rate for current so used. Cinemas and theatres are supplied with projector current and current for other special services at power rate, and there is no justification for any compromise. It is in the best interests of the supply authorities to encourage the more widespread use of electrical energy, and not to militate against its use by these vexatious and irritating objections. After all, a power rate is justified because of the greater average demand per consumer, which helps the station load curve. If that greater average consumption is due to demand for current for feeding photographic arcs or projectors, it is no concern of the supply people. The greater demand exists and the lower charge is justified. What about the consumer who installs a motor-generator to light his premises, and pays for current at power rate? To my mind there is only one answer; if he cares to incur the initial expense, and go about his lighting in such an inefficient manner, he will require a greater current supply and is entitled to the privilege for which he is paying. His case is on a par with that of the cinemas."

New Books.

THE THEORY OF MODERN OPTICAL INSTRUMENTS.—A second edition of a translation of this treatise by Dr. Alexander Gleichen has been published by the Department of Scientific and Industrial Research, for whom it is issued by H.M. Stationery Office, Imperial House, Kingsway, London, W.C.2, post free 13s. 6d. In addition to making such corrections as escaped notice in the first edition, the translators have carried out further revisions chiefly by way of explanatory footnotes. While they have left the main text practically untouched, we are glad to see that they have done something towards correcting the historically inaccurate impression which the first edition conveyed as regards the origin of certain notable British lenses. We called attention to this defect when reviewing the first edition three years ago. In the present volume the chapter on the photographic objective is provided with a chronological appendix giving optical constants of a very large number of lenses, together with particulars of the date of their introduction or patenting. This compilation is certainly of great value to the student of photographic lens construction since it identifies the names by which notable objectives are known with the patent specifications relating to them. Nevertheless, it seems unfortunate that the very partial account given in the text of the commercial development of the telephoto lens could not have been amended.

New Materials.

Novex Plates. Made by Kosmos Photographics, Ltd., Letchworth.

SOONER or later a firm which has made its entrance into the photographic trade by the manufacture of printing papers extends its scope to the production of dry plates. The Kosmos Company, while one of the youngest of photo-material firms, has quickly come into the front rank through the excellence of its papers and from its enterprise in originating distinctive grades of printing paper. Not content with the large trade in its well-known bromide, Vitegas and Novex printing papers, it has recently extended its borders to the manufacture of dry plates, to which the trade name of "Novex" is also applied. Without the intention of taking liberties with the Latin vocabulary they have coined this word to be read as a purely English contraction of "no vexation," a name which has amply justified itself in the experience of users of the gaslight papers to which it was first applied.

We are quite sure from our experience that those who employ the plates for their negative making will confirm the extended use of this trade designation. Novex plates are made in four grades, namely, "Maximum Speed" (400 H. and D.); "Studio Orthochromatic" (400 H. and D.); "Extra Rapid" (350 H. and D.); and "Orthochromatic" (300 H. and D.). The two first of these are exceedingly rapid plates, the behaviour of which in the camera confirms the claim of the makers that the H. and D. marking is a genuine indication of speed. Employed with an ordinary pyro-soda developer the "Maximum Speed" yields any required degree of vigour combined with excellent gradation and with absence of any fogging or veiling. The "Studio Orthochromatic" seems to be a somewhat softer plate, admirably adapted to studio portraiture, particularly for short exposures by artificial light. Those who prefer a somewhat lesser degree of speed will find that the other two grades maintain an equally high standard in their photographic qualities and mechanical perfection. All four grades evidently represent the best modern skill of the maker of photographic emulsions, and will certainly take their place among the leading dry plates for which this country has been and is justly celebrated wherever photography is practised.

AMERICAN PORTRAITURE AT THE FAIR.—Mr. William Crooke, of Edinburgh, who has judged the exhibition of work by American professional photographers which is being shown during the present week at the Photographic Fair, has awarded the thirty-guinea cup offered by Mr. Arthur C. Brookes to Mr. F. A. Free, of 1,426, Brady Street, Davenport, Iowa.

New Apparatus.

The Apem Daylight Developing Roll Film Tank. Made by Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1.

IT seems incredible on first looking into the inside of this tank that an apparatus so innocent of moving parts should provide the means of the transference in full daylight of the exposed band of film from its spool to the tank in a way to permit of its subsequent development. The only working mechanism, if such a description may be used, is a thin spindle placed across the width of the tank about two inches from one end. The spool of exposed film is placed within the space between this roller and the end of the tank, and the paper wrapping passed under the roller and then in a loop

back out of the tank after the lid has been put on. Then, as shown in the drawing, the wrapping has simply to be drawn completely away in order to leave the length of film extended in a bubble loop, uncoated side outwards, in the tank. This apparent feat of legerdemain is made possible by the provision of a length of fine metal webbing attached to the lid of the tank, the removal of the paper wrapping moving the film band in the opposite direction within the tank. A light-trapped inlet in the lid of the tank provides for the admission of developer and a screw cap outlet for removal of the latter and for washing the developed film before fixing, which latter operation may be done either in the tank itself or by removal of the film to an ordinary dish. The apparatus is very well made in nickelled metal, and is obtainable in five sizes for films from 2½ x 1¾ inches to 5½ x 3½ inches, at prices from 17s. to 37s. 6d. Developing powders for use with it are supplied at from 1s. to 2s. per box of six packets.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MAY 8.

City of London and Cripplegate P.S. "Printing Dodges." G. C. Weston.
Southampton Camera Club. "Carbro." A. Dordan Pyke.
Wallasey A.P.S. Members' Review of Exhibition.

TUESDAY, MAY 9.

R.P.S. Third Hurter and Driffield Memorial Lecture. "The Interpretation of Light Sensitivity in Photography." Prof. Dr. The Svedberg. At the Royal Society of Arts, John Street, Adelphi, W.C.2, at 8.
Bournemouth C.C. Outing. Horse Shoe Common.
Cambridge Photo Club. "Photograms of the Year," originals.
Hackney Phot. Soc. "Amateur Photographer" Prize Slides.

WEDNESDAY, MAY 10.

Croydon Camera Club. Display of Outing Prints.
Dennistoun A.P.A. Demonstration for Beginners. Leading Up.
Hackney Phot. Soc. Outing to Whipp's Cross.
Photo-micrographic Soc. Annual General Meeting, [illegible].
Rochdale A.P.S. [illegible] Photography." J. C. W[illegible].

THURSDAY, MAY 11.

Hammersmith Hapsburg House P.S. "The Possibilities of a Small Camera." E. Homan.
Optical Society. Ordinary Meeting.

SATURDAY, MAY 13.

Dennistoun A.P.A. Outing—Castlemilk Estate.
Hackney Phot. Soc. Outing—Ayot to Wheathampstead.
Wallasey A.P.S. Outing. Burton and Puddington.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 2. Mr. Dudley Johnston in the chair.

A paper on "The Reproduction of Pictorial Work by Modern Methods" was read by Mr. E. L. Turner, who briefly outlined the technics of the half-tone process, rotary photogravure, and photo-litho offset. He explained that none of these processes was able to give a tonally facsimile reproduction of an original. In rotary photogravure there was marked deficiency in the rendering of the deepest shadow tones.

A lively discussion followed, chiefly on the fine etching in the half-tone process, the speakers including Messrs. A. J. Bull, E. A. Bierman, W. J. Cartwright, F. W. Jackson, A. J Banfield, F. T. Usher, and Maxwell Wilson. A hearty vote of thanks was accorded to Mr. Turner.

CROYDON CAMERA CLUB.

Mr. G. E. W. Herbert gave a highly interesting lantern lecture on the "Isle of Purbeck," consisting of a walk along the coast from Studholme to Lulworth Cove, with occasional trips inland. He claimed, for the length of the ground, it was without rival for varied picturesqueness, and certainly the pictures supported this contention.

Almost the entire route was photographed, the scenery in advance of the standpoints adopted, and often the country already traversed, looking backwards. This necessitated many slides—in fact, far too many. Mr. Herbert's stuff was really good, and it was a pity atrophy was induced by a surfeit.

At the conclusion of the lengthy lecture, further slides, unconnected with the subject, were thrown in as "makeweight." There was a subtle humour about this, appreciated by the members, who thus acquired a second wind. All the slides were from roll films, and their crystal-cut appearance was favourably commented on.

In the discussion, Mr. Harpur, whilst praising their general quality, felt that the lecturer "had not got much inspiration from the pictorial element, as was evidenced by a sneaking regard for avoiding anything pictorial." Only Mr. Harpur can phrase things like this, and one is enough. But he should have excepted not a few slides well up to exhibition standard. In reply to a hearty vote of thanks for an enjoyable evening, the lecturer mentioned the film negatives were stereos, demanding treatment not always in sympathy with art principles.

Next, "A Criticism of the Affiliation of Photographic Societies," by the Editor of "The Club Photographer," appearing in the April number, was considered. Though the Croydon Club is a loyal supporter of the Affiliation, all agreed that no objection could be raised to fair criticism, however adverse. But the particular method of criticising it adopted by the Editor of "The Club Photographer" was (to put it mildly) referred to in terms the reverse of complimentary by speaker after speaker. Finally, a formal protest was unanimously registered at "the regrettable and deplorable way in which the matter had been dealt with by him."

It should in fairness be also recorded that a firm conviction was expressed that the great majority of the famous Liverpool Society, whatever opinions they might have as to the value of the Affiliation, would resent being associated with the article in question.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.

The fourteenth annual meeting of this Society was held at the headquarters, Plough Hall, Lewisham, S.E., on 26th ult., when Mr. P. R. Salmon was re-elected president, and Mr. H. D. Fretwell (10, The Grove, Greenwich, S.E.), hon. sec. and treasurer. Although badly hit by the war, a most satisfactory year's working was reported; 25 new members joined during the past season, and there were 10 resignations, mainly removals from the district; the active membership is now 76, and the average weekly attendance 30. The expenses were a little in excess of the receipts, but the treasurer reported a balance at the bank of nearly £4. All were most optimistic, but some time must elapse before the club can get back to its pre-war membership roll of 120. The Society is one of the most curiously constituted in the photographic world, and an insuccessful attempt was made to place the Society upon an orthodox footing; older and, maybe, wiser minds prevailed, however, and the Society will continue upon the lines it started. The Society, in brief, is an offshoot or satellite of the South Suburban Camera Club, a body one hears or knows little about—one founded on strict business and legal lines, and registered under the Friendly Societies Act.

GLASGOW AND WEST OF SCOTLAND SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

The monthly meeting of the Society was held in the Religious Institution Rooms, Glasgow, on April 28, 1922, Mr. J. R. Brinkley, president, in the chair.

Interesting and instructive papers were read by the following gentlemen :—

Mr. J. Doig on "Panchromatic Plates and their Uses."

Mr. A. Fairbairn on "Business Methods in Photography," and

Mr. J. Douglas Ritchie on "Reminiscences and Experiences."

There was also exhibited to the meeting a very fine collection of prints by Mr. Herbert Lambert, of Bath.

It was decided to hold a photographic exhibition under the auspices of the Association in the autumn of this year, and the hope was expressed that not only the members but outsiders would participate in the exhibition.

Votes of thanks to the lecturers, Mr. Lambert and the Chairman terminated the meeting.

Commercial & Legal Intelligence.

LEGAL NOTICES.—At an extraordinary general meeting of the members of the Morland Studios, Ltd., held at 37, High Holborn, W.C.2, a resolution was passed to the effect that the company be wound up voluntarily, and that Mr. Richard George Brake, 33, Mulgrave Road, Neasden, Middlesex, be appointed liquidator. Creditors are required, on or before May 15, to send particulars of their debts or claims to the liquidator.

NEW COMPANIES.

PI-RA, LTD.—This private company was registered on April 21 with a capital of £3,000 in 2,450 ordinary "A" and 550 ordinary "B" shares of £1 each. Objects: To adopt an agreement with F. W. Cook, A. H. Phillips, J. A. Houlton, and J. Nevitt, trading as the Pi-Ra Photo. Co., at Terrace Gardens, St. Albans Road, Watford, for the acquisition of the freehold buildings, works and factory there, and the stock, plant, fixtures, etc., used by them in their business of photographic picture-postcard manufacturers. The subscribers (each with one "A" ordinary share) are: G. Stracey, 100, Mildred Avenue, Watford, director, and F. W. Cook, 23, Malden Road, Watford, chemist. The first directors are: F. W. Cook (managing director), J. Nevitt, and G. Stracey. Qualification: 100 "A" or "B" shares. Registered office: Pi-Ra Works, Terrace Gardens, St. Albans Road, Watford.

LESTY AND CO. (1922), LTD.—This private company was registered on April 24 with a capital of £1,000 in £1 shares. Objects: To carry on the business of lithographers, stereotypers, letterpress, music, photographic, intaglio and colour printers, printers' contractors, etc. The permanent directors are: A. G. Jackson, 92, Chancery Lane, W.C., stationer, etc., and E. H. Diprose, 9 and 10, Sheffield Street, Kingsway, W.C.2, printer.

THE NEW KOSMOS FACTORY.—Visitors to the exhibition of the Royal Academy this year will find in the Architectural room an exhibit, No. 1,228, of special interest to them. This is the drawing of the front elevation of the new factory which is in course of erection at Baldock by Messrs. Kosmos Photographics, Ltd. The architect, Mr. Thomas H. Burditt, a cousin of Mr. W. H. Burditt, of the Company, has adopted a beautiful design based on the Greek style, and embodying, so we are told, the results of recent investigation of Greek architecture, from which it is found that the frontal facade of an ancient Greek building is not a flat surface, but part of a sphere having a very great radius. Extraordinary pains have been taken in the case of the Kosmos factory to carry out this plan, with most successful results as regards the beauty and dignity of the building. The factory has been designed upon a very large scale, and provides for expansion of the Company's business without disturbing the scheme of the departments according to which material pursues a continuous course in process of manufacture.

News and Notes.

HOUGHTONS PROFESSIONAL BULLETIN in its latest issue has some interesting notes on American professional photographers and their studios by Mr. Reginald Haines, who visited the United States last year and attended the Convention of the Photographers' Association of America.

A SWISS NATIONAL PHOTOGRAPHIC EXHIBITION is to be held at Geneva in May next year. Wide support has been obtained for the exhibition, which will include within its scope both professional and amateur photography. Particulars are obtainable from M. P. Rudhardt, at 12, Boulevard du Theatre, Geneva.

PHOTOGRAPHIC BARGAINS is the title of the 52-page list of second-hand cameras of all descriptions, but chiefly the folding pocket instruments for film and plates issued by Messrs. Wallace Heaton, Ltd., 17-19, Change Alley, Sheffield. The list includes also particulars of a great number of lenses. It is sent on receipt of 2d for postage.

MESSRS. W. BUTCHER & SONS are issuing a series of complete outfits at prices from 18s. 6d. to 62s. 6d., including dishes, dark room lamp, measures and essential chemicals. A special leaflet and window bill drawing attention to the sales to be made of these goods in connection with the All British £3,000 competition are obtainable by dealers on application to Camera House, Farringdon Avenue, London, E.C.4.

THE WESTMINSTER PHOTOGRAPHIC EXCHANGE, 119, Victoria Street, London, S.W.1, sends us a 44-page list, about one-half of which is devoted to cameras and other accessories for the amateur photographer, representing the most recent introductions of photographic manufacturers, whilst the other half is a list of second-hand roll film, plate, focal-plane, reflex and other cameras. The list is obtainable free on application.

THE PHOTOGRAPHY OF GOLFING STROKES.—The golfing world is now very much interested in some slow-motion photographs of Harry Vardon's strokes, which are now being shown, and portions of which are being reproduced in the illustrated Press. The pictures, it is stated, were taken at the rate of 160-200 per second, instead of the normal rate of 16 a second, the projected rate (also 16 a second) allowing golfers to study the slowed-down movements carefully and comfortably.

PORTRAITS BY MR. HERBERT LAMBERT.—There is being shown in the foyer of the Covent Garden theatre, during the present season (May to July) of grand opera, a collection of photographic portraits by Mr. Herbert Lambert of modern British musical composers. The collection exhibits Mr. Lambert's art in its virility, for all of the portraits impress one as strong character studies of notable personalities. Lovers and students of music, of which Mr. Lambert himself is one, will obtain a few minutes' pleasure by stepping aside from the shabby thoroughfare of Bow Street and looking at these fine examples of his artistry.

PREPARATION OF COLLOIDAL SILVER.—Five gms. of albumen is dissolved in 25 c.c. of water by the aid of 0.75 gm. of sodium hydroxide and warming on a water bath. The solution is then filtered. Silver oxide prepared from 10 gms. of silver nitrate and washed by decantation is then mixed by stirring with the albumen solution, and the mixture diluted to 200 c.c. and warmed for an hour on the water-bath. After cooling, it is precipitated with acetic acid, and the precipitate washed with very dilute soda solution, then dried. The product contains 75 per cent. of silver.—*Journ. Soc. Phys. Chim., Russ.*, through *Amer. Drugg.*, February, 1922, 42.

SECRET PHOTOGRAPHY AT THE ZOO.—According to the daily papers the authorities of the London Zoo are very much concerned about some natural history pictures now being shown at the picture halls, and taken unmistakably at the Zoo, and inquiries are being made as to how these were obtained. Though it is thought possible that they may be reproductions from old films known to have been taken surreptitiously about two years ago, it is suspected that they are new ones taken recently with a portable apparatus fitted with a gyrometer to obviate the use of a handle. Reliable films of animal life in the Gardens have been taken by the official cinematographer, and these, it is understood, will be released for public exhibition so soon as the approval of the Council has been obtained.

HARDENED GELATINE IMAGES.—A patent specification (No. 175,988, of P. Schrott, 98, Hauptstrasse, Vienna), which is abridged and open to inspection under the International Convention, relates to a process for obtaining images consisting of hardened gelatine. To transform a silver image into a tanned gelatine image by hardening the gelatine in the presence of the image by a bichromate, the silver image is first treated in a bath, such as copper bromide or chloride or silver ferrocyanide, to obtain a compound metal image which acts as a reducing-agent to a bichromate, and the image is then treated in the bichromate bath. A yellow image is formed which is an indication that the tanning is complete. The metal image can be dissolved out by acid leaving a clear tanned gelatine image which can then be coloured by dyes, or a greasy printing colouring matter can be used and the image used as a phototype.

SHOPPING-WEEK PHOTOGRAPHS.—This week the Catford, Lee, and Lewisham traders are having a special shopping week, and photography is playing its part in the events of the week in these South-East London districts. We clip the following from the official programme, a copy of which was delivered at every house in the districts named:—A prize for photograph of the brightest smile during the week; also a prize for the smiler. A guinea for a smile. Whenever you see a camera during Shopping Week, smile; it may bring you a guinea. That prize will be given to the owner of the best smile found in the shopping area during Shopping Week. A guinea for the photographer who photographs the best smile. Never mind whether you know the owner or not. If you see a good smile, snap it. Send the print to, or hand the negative into, Leslie's (a local chemist and photographic dealer). The prints will be judged by the Catford Camera Club Committee.

PACKING CASES FOR AMERICA.—We all know that there is a tariff on almost all British goods entering the United States, but not everybody knows the far-reaching effects of these tariffs. A writer in the "Evening News" calls attention to a very curious state of affairs. "I have been hearing," he says, "a lot about packing cases. These, like their contents, are dutiable, it seems, and the amount to be paid depends on the amount of the tax upon their contents. For some things, therefore, the tax on the packing case is a very heavy item. But packing cases made of American wood go in duty free, with the result that a new industry is springing up in this country, the manufacture of packing cases from American wood specially imported for the purpose. One large exporting agent I met yesterday is circularising his clients, insisting on their sending their goods packed in cases of American wood. The extra cost involved is less than the amount of the duty."

PHOTOGRAPHY IN ROYAL PARKS.—The free use of hand cameras in Bushey, Green, Greenwich, Hyde, Regent's, Richmond, Hampton Court, Primrose Hill, and St. James' Parks has now been sanctioned by the Office of Works. This concession was announced in the House of Commons last week. Sir John Gilmour, as representing the First Commissioner of Works, said that permits would not in future be necessary for hand cameras in the unenclosed portions of the Royal parks, but as the unrestricted use of stands and cinematographic cameras might cause obstruction and lead to infringement of the general regulations on trading in the parks, the First Commissioner of Works did not see his way to modify the regulations in that respect. It is to be hoped (writes a correspondent) that park-keepers and others concerned have been made acquainted with the concession, as although the "Red Book" has for many years served as a permit, many keepers have been ignorant of it, and have caused a considerable amount of trouble.

REVERSAL PROCESS. According to a patent, No. 176,357, of Kodak, Ltd. (assignees of J. G. Capstaff, Rochester), under the International Convention, in a reversal process, more particularly for cinematograph film negatives, the second exposure to light, after removing the first image, is controlled in accordance with the characteristics of the remaining emulsion as to its tendency towards re-reversal, its printing value and its contrasts. Also, previously to the second development an alkali bath may be used. The steps of the complete process are (1) exposure, (2) development, (3) washing, (4) reversal, i.e., removal of the silver image, (5) washing, (6) clearing by a bisulphate bath, (7) rinsing, (8) ascertaining the characteristics above-mentioned, (9) treatment in an alkali bath, which may be optional, (10) rinsing, (11) exposure to controlled light, (12) developing, (13) rinsing, (14) fixing with acid hypo. Particular formulæ are included for steps (2), (4),

(9), and (12). To ascertain the exposure for step (11) a test strip of film is cut off, the pictures exposed to a standard light beneath a series of density filters, and developed. The alkali bath of step (9) is adopted if the test film shows a tendency to reversal when developed.

LONDON CHAMBER OF COMMERCE.—The 40th annual general meeting of the London Chamber of Commerce was held on Wednesday last at the Skinners' Hall, Dowgate Hill, E.C., Mr. Stanley Machin, J.P., in the chair. The report of the Council of the Chamber on the transactions of the past year referred to the Italian duty on photographic papers, and stated that in view of the cancellation of the commercial treaties between Italy and Austria-Hungary, with the consequent abolition of the conventional rate of duty on certain goods, including photographic paper, it had been suggested to the Board of Trade that efforts should be made to obtain from the Italian Government special tariff treatment for such British papers. The Board replied that the matter would receive their consideration, and that the observations of the Chamber had been carefully noted, in case it should be possible to raise the question with the Italian authorities. Passing on to the work done during the 12 months by the various sections of the Chamber, the report states that the members of the Scientific Instrument, Optical and Photographic Section had maintained a keen interest in the various stages through which the Safeguarding of Industries Act, 1921, had passed. Every effort was made to secure the passage of the measure, and to ensure the inclusion of scientific and optical instruments in the Schedule of Part 1 of the Act, which is now, of course, an accomplished fact.

GERMAN OPTICAL GOODS.—The Board of Trade give notice that they have received under Section 2 (1) (*b*) of the Safeguarding of Industries Act a complaint by the British Optical Instrument Manufacturers' Association, Ltd., the British Photographic Manufacturers' Association, the Spectacle Manufacturers' Association, and the Drawing Instrument Manufacturers' Association in regard to the sale of optical and other scientific instruments manufactured in Germany. The Board of Trade, in exercise of the powers conferred upon them by Part II. of the Safeguarding of Industries Act, 1921, have referred the matter for inquiry to a Committee constituted for the purpose of that part of the Act and consisting of :—Sir R. Henry Rew, K.C.B. (Chairman), Mr. A. K. Davies, Mr. Rayner Goddard, Mr. A. E. Holmes, and Mr. J. F. Mason, J.P. The Committee propose to hold their first sitting for the taking of evidence at 3 p.m. on Monday, May 15,. 1922, at the Hotel Windsor (Mines Department), Victoria Street, London, S.W.1. The Secretary to the Committee is Mr. T. Turner, Board of Trade, Great George Street, London, S.W.1, to whom all communications should be addressed. In accordance with the statutory rules applying to the procedure of committees appointed under the Safeguarding of Industries Act, the sittings of the committee at which evidence is taken shall be held in public, except that the committee shall refuse to allow the public to be present at any proceedings during the hearing of evidence on matters which, in their opinion, are of a confidential character.

Correspondence.

THE EXHIBITION OF AMERICAN PICTORIAL PORTRAITURE.

To the Editors.

Gentlemen,—The Exhibition of American Pictorial Portraiture, which is now being held in connection with the Photographic Fair, has this feature of interest, that, being entirely composed of the work of the one country, an opportunity is afforded of comparing American portraiture in its general characteristics with our own. That the recognised leaders in photographic portraiture in that country have not exhibited is not surprising, considering the conditions of the competition. The valuable cup, which was the sole prize, was well worth winning, and the authority of the appointed judge, Mr. William Crooke, of Edinburgh, is beyond question, but there could only be one winner, and in the keen competition for supremacy the fear of being among the losers has proved more potent than the expectation of being exalted.

The competitors, I should judge, are generally of a similar class to the best photographers of our medium-size towns, and the second best of the more important towns and cities; that is to say, the best of our photographers, excluding the comparatively few whose reputation and whose work are well known to everyone in photographic circles. The exhibition, as a whole, no doubt would have gained in some respects by the rejection of perhaps thirty more prints than have been rejected, but it was considered that its purpose would be better served by hanging each exhibition set as a whole, wherever possible. Everyone who sent in has had at least two pictures hung. A few only have been rejected—all small prints—and in each case it was an act of mercy as well as of necessity arising from want of space. Thus the opportunity has been given of seeing both what the author rightfully thinks is good work, but also what he wrongfully believes so.

It is quite clear that our brethren across the seas are, most of them, as liable to fail in choosing the best of their work for exhibition as specimens of what they can do as most of our own professional photographers are. In many cases a set of six on the walls consists of three, four or five very creditable pictures, good, sound every-day professional work, and the remainder of an altogether lower standard. This clearly arises from want of ability to distinguish the good from the bad. Probably a better set might have been chosen from the specimens on the reception-room table. There are a few exhibits that can only be described as freaks. An attempt at originality in the treatment of the subject, it if succeeds, may be a work of genius, but if it fails it is merely a freak. The divisional line is a very narrow one. An unusual treatment of the print, if the result is unpleasing, may also be described as a freak. There are a few examples of that, but, on the other hand, there are prints unusual in appearance that require closely looking into to discover the method employed, that are pleasing.

There are not so many examples of "spot lighting" as one might expect to find. It is a very valuable aid to effects when skilfully used, but the ignorant are apt to imagine that it may be used indiscriminately; that because it is fashionable it must necessarily be good. There are examples both of its good use and misuse.

Many of the exhibitors sent letters, on their usual letter paper, notifying the sending off of their pictures, printed with a list of their awards at various exhibitions in the States. It is evident that many professional photographers there make a practice of exhibiting their work publicly. It is a practice that should be more frequently followed here. There is no method of learning the faults of one's work more effectual than seeing it in contrast with that of others, but in preparing work for exhibition some thought should be bestowed on the conditions to be dealt with in preparing an exhibition. A photographer may imagine that a large margin of mount to his print will enhance its effect, but wall space is limited in extent, and an unreasonable area of mount may entail the alternative either of cutting down the mount or rejecting the picture altogether. To send a print under 12 x 10 on a 24-in. mount is almost an outrage.

In these notes I have dealt more particularly with the faults to be discerned, but it must not be supposed that they are greatly conspicuous in the exhibition. The collection is really a very interesting one, and is strikingly different from what a similar collection of British professional work would be, and the prints generally are much larger. In America large direct photographs have always been more popular than here, possibly because they have more money to spend. If I have suggested practically only what there is to avoid, it is not because there is little to admire, but simply because I should have to extend my article to more than double its length, and the space is not available.

ALEXANDER MACKIE.

PHOTOGRAPHERS' STATIONERY.

To the Editors.

Gentlemen,—Allow us to thank you very much indeed for the kind reference you make to our letter headings in yours of to-day. You will see from the enclosed tabulated list that we have gone pretty thoroughly into this of late, and have added a considerable number of new designs. No charge whatever is made for the use of these designs, which have almost all the virtue of an original

design to the individuals using them, because we restrict their use to certain localities—that is, if a photographer in any one reasonably limited district uses a certain design, we do not allow that design to be used by any other photographer in that district.

While we are on the subject of photographers' work, we might again refer to a subject that you have often dealt with, and that is the aptitude of photographers for dealing with block orders and printing because of their having the *initial stages* in their hands, and in this respect it might do no harm to tell you of an experience which happened recently. We had made about a dozen blocks for a photographer in the South; he advised his principals (a very large though newly founded factory) that he knew a place where he could get the printing done specially well, and he received the order, which he placed with us. That in itself was a fairly good order, and the firm concerned were so extraordinarily pleased with it that they gave the photographer a handsome honorarium in order that they might be allowed to deal direct with us for a particularly urgent job. This is unusual, perhaps, but the photographer was a good deal more than satisfied with his share in the transaction, which would never have come his way but for his enterprise in the profitable art of *suggesting*.—With compliments,

Yours faithfully,

HAROLD HOOD.

Middlesbrough, April 28.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—Judging by the discussions and differences of opinion which still continue to appear in photographic journals on the optical and precise control of the dot formation of ruled screen negative making for half-tone printing, it is evident that even the most experienced operators and authorities have different views on the subject, and to those who are engaged professionally in this particular line of work the publication of the opinion of such authorities is most interesting and valuable. Screen negative making is one of those lines of work which with a little practice and experience and sane judgment and an appreciation of the basis of relative control of such photography, can soon be operated by an average photographer either wet or dry—but as in most other sciences there is just the difference between getting first-class results and the other sort, the difference which will always exist between the work of men of different degrees of intelligence, which includes carefulness, thoroughness, cleanliness and such attributes, in addition to the essential scientific knowledge.

No doubt the majority of screen plate operators are capable, and actually do make suitable negatives, which leave little room for fault finding, as is evidenced by the enormous number of illustrations in books, newspapers, periodicals, etc., which are continually being produced and printed by this method, but I think I am right in saying that in the great majority of cases the screen plate negatives from which these illustrations are made are produced by men who work by "rule of thumb," viz., by constant repetition and familiarity with this class of work, they become so accustomed to getting certain results by certain operations that they know instinctively what the result will be, and if there be a certain percentage of results that may not fulfil ideal conditions, they can still be used for the purpose, and need not be made over again. To produce the highest quality of screen negative requires a niceness of relative adjustment that only a comparative few operators really appreciate and understand, or will take the trouble to make; in other words, the calculations of most operators are only approximate, and although some of the results may be quite good, it is frequently a case of "near enough, but might be better." The point seems to be that because there is a certain amount of latitude in the extent to which the same aperture and the same screen distance can be used with various camera extensions, this fact is abused, because it would mean a little extra trouble in making more accurate calculations, and having a larger supply of stops to choose from, the deficiencies being partly made good by later aids in cutting and faking, which are liable to injure tone values and gradation, and possibly convert an otherwise good quality negative into a second-rate one, and it seems to me that it is exactly on this point that such a system as the Doutitt apparatus supplies a simple and efficient method of accurate control.

Although the screen negative is primarily responsible for obtaining the desired result in arriving at the ultimate printing effect, there are other factors which must be taken into consideration, which may do much to improve or mar the quality of the final impression. In letterpress block making, which is mostly used in producing the illustrations in question, the etcher may easily destroy the good qualities produced by a good screen negative, by injudicious handling, in which case a second-rate negative would have answered the purpose just as well. Forcing the etching and biting to too great a depth will have this effect, converting a smooth dot into a ragged dot, the difference between machine etching and still bath or rocking—face up or face down—bad or good staging or stopping out, may make all the difference in the appearance of the result, not to mention degrees of quality in printing and paper. Even now, after many years of practical application of the process, the last word has certainly not been said as to the actual scientific effect of interposing the ruled screen which produces the screen negative. Some of the most expert operators have their own methods and pet theories on the technicalities and effect of the action of light through the half-tone screen, such as the effect of diffraction.

But are the advantages sufficient to make it worth while? Can those who advocate consideration and measurement of diffraction show superior system, speed or quality of results? And if diffraction why not reflection, halation, absorption and other variations which may take place? I think not. Life is too short, and the customer wants the job. The main thing that the operator has to concern himself with is to be as exact as possible in applying the working hypothesis which is at the root of the whole business, that the ratio of screen distance is to the screen ruling as the aperture is to the camera extension, and working accurately on this basis, the other factors do not materially affect the result.—Yours faithfully,

LOUIS H. JOHNSON.

38, Heathhurst Road, Hampstead, London.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. C.—We do not think that the fault in the photograph (if any exists, which we cannot say without seeing the child) is due to the focal length of the lens. It is probably due to an unfortunate point of view, which makes the baby look lumpy and which also makes the roost of the chair.
